PROBABLE WEATHER, WEEK ENDING SATURDAY, JANUARY 12, 1867.—Our anticipations have all been realized to the letter, and the setting of the wind at N.E. has given us a taste of real winter. Next week bright and bracing, with wind easterly, and more or less frost everywhere. Snow in places, and of no great amount. Cold increasing as the week advances.

The Gardener's Magazine.

SATURDAY, JANUARY 5, 1867.

IMPROVEMENTS IN THE CULTIVATION OF THE GRAPE VINE have been variously described and criticized in these pages of late, and we may profitably consider as of primary importance what improvements have been made in the grape itself to increase its usefulness and value. During the past few years several new varieties have been brought into cultivation, and a certain few of them have proved of incalculable advantage both for their intrinsic merits as dessert fruits and their ready adaptability to simple and inexpensive modes of cultivation. The position acquired by some of the newer kinds in competitive exhibitions is quite consistent with their fine qualities in growth, productiveness, and flavour. Thus, for example, **BUCKLAND SWEETWATER**, introduced but a few years since by Messrs. Ivory, has become as famous among grape-growers as the oldest varieties in the lists, and is a real advance in the class of white grapes, to which it most properly belongs. The vine grows well, is not subject to disease, bears abundantly, and is adapted for any kind of structure in which grapes can be grown, and is especially adapted for cool vineries. When well done, this variety produces bunches as large as those of **Black Hamburg**; and when perfectly ripe, its beauty is not excelled by any other white grape we possess. The **GOLDEN HAMBURGH** of Busby is another of the comparatively newer kinds that has become firmly established in the good opinion of grape-growers. One of its good qualities is a high degree of productiveness, but it has also beauty of bunch and berry, and refined flesh such as a connoisseur of fruit will always enjoy. Still newer as respects the date of its first distribution is the **ROYAL VINEYARD**, which has now made its character as one of the best late white grapes we possess. For some time after the first sending out of this grape by Mr. B. S. Williams, it was reported to be shy of setting; but it has lived down the accusation, and is now known to be as free as any grape of equal quality, and much more free than some of our most esteemed varieties of white grapes. A cool house is all this noble grape requires, and it may be said to be of just the same value for a late supply as **Buckland Sweetwater** is for an early supply; and those who are prejudiced against **Sweetwaters** for their juiciness, will prefer it for its rich *croquant* flesh. Yet one more white grape must be mentioned here, and that is the smaller-berryed but high-flavoured **DUCHESS** or **BUCKLEUCH**, which presents us with a rich Muscat flavour, without demanding the high temperature and skilful cultivation necessary for the production of good samples of the most celebrated of the Muscat varieties. The smallness of the berries is a serious defect of this variety. Bunches may be grown to almost any size: have we not seen them on several occasions of four to six pounds weight? Thus from the many varieties introduced within less than ten years past, we may select four white-fruited varieties of the highest value, and which every grape-grower should keep in mind as desirable when opportunity or necessity occurs for planting any of them.

Black grapes may also be found amongst the newer kinds, and first in the selection we should place **Mrs. PINE'S BLACK**, now in process of distribution by Messrs. Pince and Locombe, which was reported in the "Garden Oracle" of 1865 as a grand contribution to the English vine. This variety has been brought under our notice again within the past few weeks, and we fell bound to direct attention to it as valuable for its good qualities as a dessert fruit, and pre-eminently valuable for long keeping, and for *improving by hanging* after it is ripe—which is not ordinarily the case with either grapes or men. This is a free-setting variety, producing large bunches and full medium-sized berries, the skin tough but not thick, the flesh quite crackling, very rich, and with more of a Frontignan than a Muscat flavour. When we first tasted this grape, three years since, the Muscat flavour was distinct and peculiar to it; but in the present season—the *Volux* we have tasted of it (taken from No. 1, NEW SERIES.—Samp. X.

a bunch a foot long) were destitute of Muscat flavour, but were strongly tainted with Frontignan, the result doubtless of the bunch having hung some time. This variety will in many instances render it unnecessary to force grapes for the earliest supply, because by careful keeping, it may be served to table fresh and delicious, at the same time as the first supplies of forced grapes, which are occasionally (!) sent to table wanting a few days more to ripen them. Such good keeping kinds as **Lady Downes**, **Alicante**, **Raisin de Calabre**, **West's St. Peter's**, have an admirable addition in **Mrs. Pince's Black**, which is distinct in character and flavour from them all, and may be kept for use as late as any.

Eminently useful, too, will be the **MUSCAT CHAMPION**, raised by Mr. Melville of Dalmeny Park, and the stock of which is in the hands of Messrs. Veitch. This grape has a true Muscat flavour, and Muscat aroma, and it does not need the usual Muscat heat to bring it to perfection—an advantage of the utmost moment. The vine grows freely, and is of robust constitution, and it is at least of average productiveness, if not excessively fruitful.

Passing from these newer kinds to one of the five old kinds, it is odd that **FRANKENTHAL** and **BLACK HAMBURGH** are generally considered the same by cultivators. Of course our more accomplished exhibitors know the radical distinctions between them, but we observe in many catalogues that they are regarded as identical, which is not the case. The **Frankenthal** grown to exhibition size is remarkable for the beauty of its bunches, and its qualities as a dessert fruit are of the very highest order. It is undoubtedly the best of the **Hamburg** group, and of the same stock as that most useful of all grapes the true **Black Hamburg**. We may yet hope to see, through improved methods of cultivation, and the adoption of improved varieties that possess high flavour and productiveness, and demand only average care and skill, cheap English grapes for the tables of the people. It is strange indeed that good English grapes are scarcely yet within the means of the masses, as they ought to be.

THE FIRE AT THE **CRYSTAL PALACE** on Sunday last made a cruel end of one of the prettiest collections of tropical trees in England, and at the same time annihilated a very complete and beautiful memorial of the labours and accomplishments of the Messrs. Loddiges. As respects the palace itself, the destruction of the whole of the building on the north side of the screen is a national calamity, for this is truly a "palace for the people"; but the loss, great as it is, can be repaired by a sufficient outlay. But as respects individual trees and various interesting curiosities, we may say with simple truth that they are gone for ever, and to replace them is impossible. Many of the beautiful examples of tropical vegetation lately located where now there is a ghastly wreck, had been housed in Hackney, in Messrs. Loddiges' care, so many years as to have acquired historical importance long ere the late Sir Joseph Paxton secured them for the embellishment of the **Crystal Palace**. To enumerate the losses is impossible, but there can be no doubt now that all the larger subjects, such as the **Muss**, the **Palmetta palm**, and others by which the well-known scene was peculiarly enriched, are injured beyond recovery. Many of the smaller aquatic plants have been gathered from amongst the ruins in a living state, and have been removed to nursery quarters to receive extra care for a time; but after all that will be saved will be as nothing compared with what is lost, and the losses include many valuable and interesting animals as well as plants. The origin of the fire appears to have been in some way connected with the practice of banking up the furnace fires, and it is conjectured that a choked flue and some adjacent well-dried timbers played severally their appropriate parts in inducing the catastrophe. We regret exceedingly to observe that the attendance of holiday folk has fallen off tremendously since the occurrence of the fire, and the diminution of receipts therefore adds to the embarrassment of the directors. We wish it to be known to our readers that all the entertainments specially prepared for the season are untouched, and for holiday merry-making the palace may be regarded as perfect as ever. Thousands of persons accustomed to visit the palace at this time of year never went beyond the screen, for the music and fun taking place in the transept were enough for them. There is therefore, as regards the entertainment of all such, no diminution of attraction, and we trust when this becomes fully known the public will swell the receipts to a degree sufficient in a great measure to promote the restoration of the structure to its former completeness and beauty.

TO DIE TIMBER WHILE IT IS GROWING is an ingenious proceeding, possible and practicable, but whether desirable remains to be ascertained. At the conservation of the **Crestmore** Agricultural College, Mr. Hyett exhibited sections of woods stained with various hues by means of metallic salts introduced to the sap of the living tree. The commercial value of the

process may not be immediately determinable, but the carrying it out on a large scale must of course turn upon the relations of monetary outgoing and incoming in the proceeding. Not so the scientific value of the process. It must be that the infusion of dyes into living woods will contribute something to our vague knowledge of the motions of the sap, and we do hope that science has herein furnished us with a new instrument for experimental inquiry on this important subject.

PARIS UNIVERSAL EXHIBITION OF 1867.—The British Commissioners for the Paris Exhibition of 1867 have issued from South Kensington a long series of "general questions which apply to all cases," which must be duly answered, signed, &c., by those who intend to advance their claims to the new "Distinct Order of Reward" which is to be adjudged at the Paris Exhibition of 1867. This particular order was instituted in favour of persons, establishments, or localities which by a special organisation or special institutions have developed a spirit of harmony among all those co-operating in the same work, and have provided for the material, moral, and intellectual well-being of the workman. The rewards consist of ten prizes of the total value of 100,000 francs (£4,000, or £400 each, and twenty honourable mentions. One grand prize of 100,000 francs may, in addition, be awarded to the person, establishment, or locality distinguished under this head by a very exceptional superiority. The form which is now issued must be filled up by or on behalf of any person, establishment, or institution in the United Kingdom for which the reward is claimed, and must be forwarded to the "Secretary, Paris Exhibition, South Kensington Museum," on or before the 26th inst.

THE ALOCASIA.

The prominent position which some of the best varieties of this truly beautiful genus generally occupy in most collections of plants distinguishable for the beauty and magnificence of their foliage at our principal horticultural exhibitions, is a pretty sure indication, if not an ample and conclusive proof, that the *Alocasia* is worthy of our attention, and has some claims upon our notice; for without doubt, no collection of fine-foliage plants which requires the assistance and advantages of a stove, combined with a liberal supply of heat and moisture for their successful management, can approach anything like competition unless it contains some varieties of the genus. I am, under the impression that I shall not be speaking far from the truth when I say that if well grown, *A. macrorhiza variegata* and *A. metallica*, two of the oldest kinds, saying nothing about the later introductions, are without exception two of the grandest ornamental leaved plants that we could possibly have for the decoration of the stove or the ornamentation of the exhibition table.

Before turning our attention to the cultivation, which by the way is by no means difficult, provided proper means are at hand, I may as well say that unless the convenience of a stove or some other house furnished with a plentiful command of heat, and sufficient space for the full and proper development of the plants, is obtainable, it will be only a useless and wasteful expenditure of time and patience to attempt to grow the best kinds. Of course the common greenhouse sorts, which are so extensively employed in outdoor decoration during the summer months, are an exception to this rule, and as they were ably treated in the magazine a short time since, it will be quite unnecessary for me to say anything about them, consequently I shall confine myself to those varieties requiring stove treatment. The best way to pot *metallica* and similar kinds is the same way as some of the orchidaceous plants are potted. Fill the pots about half full of large pieces of crocks, with a layer of rough lumps of peat to keep them from getting choked with the finer material; the plant is then potted in peat mixed with silver-sand and finely broken crocks; the crocks should be thoroughly clean. In selecting the peat, I am careful to use only that which has a large amount of fibres, and then shake out the finest portion, and only use the rough part; for so far as my experience goes in this respect, I consider it one of the most important and essential points in the culture of this section of the *Alocasia* to keep the roots out of close soil; it is next to impossible to grow the plants in it, for the roots are so thoroughly impatient of being confined that they will very soon rot if they are. Not so long since, I had a plant of *metallica* which lost a very large portion of its roots through the material in which it was potted, getting close and sour, aided by being kept in the conservatory until late in autumn; and for the benefit of any one who might be similarly situated at any time, I will describe what measures I resorted to to bring it back into a healthy condition again. As soon as the plant was brought from the conservatory, as much of the sour stuff was removed from amongst the roots as was consistent with the safety of the plant, and without giving it too great a check; and I then gave it a fresh pot, fresh soil, fresh crocks—in fact, a fresh start in life altogether, and plunged it in the tan bed amongst the pines, and there it remains now. The pot is a mass of healthy roots, and at the present time the plant is starting into a vigorous growth, just as though nothing had happened to impede its progress. It will not be out of place for me to observe that for ordinary purposes this is much too early to start them into growth; the end of February or beginning of March is quite soon enough, for generally speaking fine-foliage plants are not wanted to be in perfection until after the pelargoniums, azaleas, and other brilliantly tinted flowers are over,

and turned out into their summer quarters, and the different occupants of the flower garden at their best; it is then, to my way of thinking, that fine-foliage plants are required for indoor decoration. I wish to be understood the specimens more particularly of those possessing high-coloured leaves now, for one is able to appreciate them better than when they are placed in juxtaposition with showy flowers like the above-mentioned subjects, and are moreover a great relief to the mind from the gaudy colouring which so generally prevails out of doors at that particular season; and few things are so thoroughly refreshing to the sight after it has been dazzled with the brilliancy of the gay colouring of the parterre as a house nicely furnished with a good collection of beautiful leaved plants.

With an apology for this digression from the cultural remarks, I will return, and perhaps it will be as well to say that my reason for allowing the plant I was speaking about to remain in the conservatory so long was to give it its rest a couple of months earlier than it otherwise would have had it, on account of my requiring it at its best early, for a particular purpose. Like most fine-foliage plants, this requires plenty of water at the roots when growing, and this section must not be kept too dry in its resting season. When growing, the plants require an abundance of atmospheric moisture, which is best obtained by sprinkling the paths and stages, for if syringed overhead, even with the clearest water that can be conveniently obtained, there certainly will be a settlement and spotting on the leaves, more or less in proportion to the purity of the water used; and when the leaves are sponged, to wash off the sediment, it very materially spoils that exquisitely beautiful metallic lustre which is the principal charm of this section, under which I shall include *A. metallica*. This variety is sufficiently well known to every one who has any knowledge of plants to render any description unnecessary. *A. zebrina* is a very magnificent kind, much stronger growing than the preceding; its beautiful large velvety green leaves are produced on prettily marked stalks, which when well grown average from two to three feet high. *Caladium Lowii* and *Veitchii* will succeed under this treatment. It might not probably be exactly right to say anything relating to caladiums in a paper specially devoted to alocasias; but I trust the great resemblance these two varieties bear to the alocasia, both in manner of treatment and style of growth, besides their being introduced to this country under the same name, will be a sufficient justification and excuse for mentioning them here.

A. macrorhiza variegata is a very noble plant, and requires a somewhat different system of treatment to that recommended for the preceding varieties; it wants something more substantial to grow in, and nothing beats good fibry loam, thoroughly decomposed manure, leaf-mould, and a sprinkling of silver-sand. I mix and use it in the proportion of three parts loam and a part each of leaf-mould and rotten dung, and sufficient sand to make the whole feel gritty. This compost beats peat out of the field for growing this sort. I bought a plant of it not more than a twelvemonth since with only a couple of leaves, the stem the thickness of one's thumb, and now its bulb stands very near a foot high from the level of the soil, and measures as much, or more, in circumference, with half a dozen smaller ones considerably longer than the original one was when I first had it, and I expect to find two or three dozen smaller bulbs when I take it out of the pot it is now in. I have the plant dried off in the pot lying on its side in a temperature of 50°. Some time last February the plant was shook out of the old soil, and potted in a 48-size pot in the soil as I have recommended, and then plunged in a bottom-heat of something like 70°; I am unable to say to a degree, neither is it of any consequence that I should do so, for a few degrees either way will not signify; but I may observe, in passing, that 70° should not be exceeded to any great extent by those who are inexperienced in the management of bottom-heat. As the plant grew, I kept it shifted and plunged in the bottom-heat until it reached a No. 4, which was some time towards the end of May, and it was too large to be put back into bottom-heat, for there was not sufficient room for the immense leaves which began to push up to develop themselves. As soon as it began to fill the last pot with roots, I stood it on some pieces of brick in a pan of weak manure-water, allowing the pot to be about an inch deep in the water. I was certainly surprised to see how vigorously it grew after this, and it was nothing comparable in June, when I exhibited it at Kingston, to what it was a month or six weeks later: the leaves were scarcely half the size. I was in doubt as to whether growing this kind so vigorously had any influence upon the variegation, so in the autumn I potted two small plants very equally matched in every respect, one in peat and sand, and the other in the same soil as I have been speaking about; they have stood side by side, and had exactly the same kind of treatment. They have been kept growing up till now; the one in loam is decidedly the largest plant, and better variegated than the other. *Metallica* is propagated by division, and *Macrorhiza variegata* by the small bulbs which will be found amongst the roots, and those adhering to the parent.

GEORGE GORDON

KITCHEN GARDEN SOILS, AND THEIR MANAGEMENT.

RECLAMATION OF CLAY SOILS.

I am aware that the heading of this paper might lead the reader to expect an elaborate treatise upon the subject; but such I shall not attempt, because it is, in the first place, almost inexhaustible, and secondly, because it is imperfectly understood even by those whom it most concerns; and the best that we can do at present is to gather materials towards a full understanding of it. I therefore propose to treat this subject in my usual plain way, that our gardening readers may understand it, and that I may not be tempted to go out of my depth. I am the more anxious to so treat it because it is important that those who have not previously given the subject any consideration should do so, as on a proper understanding of it depends in a great measure the success of much of their labour. This last is such an important question to the kitchen gardener, that I may hope for an attentive perusal of the following remarks, as I hope to go through most of the essential features appertaining to kitchen garden soils and their management. I shall first dwell upon

SOILS FOR A NEW GARDEN.

It does not come within my province here to enter into the choice of positions; I rather prefer to take them as we find them on any given spot; and I shall first suppose that we have a soil with 8 or 10 inches of good surface earth, resting on a blue or yellow clay. Such a spot is by no means to be despised, although I have seen such valuable positions badly managed—in fact, I may say spoilt for the first few years of their use, for want of a proper knowledge of the subject. I am bound to say that there are many spots where the skill of the gardener is called into more active exercise to secure the well-doing of his crops than these, and the greatest mistake committed by many is, when first handling such a soil, they have generally seen, or somewhere read, that every new kitchen garden should be well and deeply trenched, and upon the strength of such knowledge they proceed to follow out the instructions without giving any consideration to the peculiarity of soil or position, and by so doing they create an enemy that is not got rid of in a day or a year. Without giving the subject any thought, the ground is trenched sometimes from two to three feet, all the best soil being placed in the bottom, and a strong rank clay brought to the surface in its place, which will take years of careful management to bring into a good working condition, unless after a year's working the ground is trenched over again, and the soil that was at the top in the first instance is brought to the surface again.

Now the order of proceeding in such a case should be, not to place the top soil in the bottom of the trench, but endeavour as much as possible to put it on the top again; and this operation is very simple, for instead of bringing the bad soil to the top, the bottom of the trench may be loosened up to the required depth (2 feet is sufficient in such a soil), and allowed to remain there, and the top spit of the next trench placed on the top of it. By this means the surface soil is retained at the top, and the cultivator will find it much the better for working, as well as for his crops, than if he had brought the bottom soil to the surface. Mistakes in this simple operation in the first instance when forming a new garden are by no means uncommon, but evidently committed without first giving the matter any degree of thought. Not many years since on the borders of Kent, I saw a large nursery famous for rose-growing, where a like mistake had occurred. It happened that a new ground foreman was engaged, whose notion of deep trenching was so great that he prevailed upon the proprietor to have every vacant piece of ground trenched up 2½ feet deep; and in conducting the operation, the top soil was placed in the bottom, and a depth of a foot of calcareous clay brought to the surface. The consequence was that what was before a kind, workable surface soil, was converted to a cold, stiff, ungenial surface, that had it been allowed to remain would have cost years of expensive management before it could be got into a kindly friable condition. But in this instance, one season's working proved to the owner that for him a serious mistake had been made, and the shortest and best remedy he found was to re-trench the ground, and bring again the original surface soil to the top. I have merely related the above facts that have come under my own observation to show that the subject is sufficiently important, to demand the serious attention of all who may be engaged in such work, for as shown in the above instance, unless a proper amount of attention is given the subject at the right moment, the neglect of it may prove a serious affair to all interested.

But from what I have above stated it must not be inferred that I am opposed to deep trenching, because few writers have advocated the advantages of deep stirring of the soil in stronger language than I have in these pages; but at the same time, experience and observation have taught me that trenching as ordinarily understood is not applicable to all soils, but when there is a sufficient depth of good soil to allow the bottom to be brought to the top, then I would by all means advocate its being brought there, but in other cases where the subsoil is of that retentive

nature, it is better for all the purposes of cultivation that it should not be brought to the top unless the cultivator can afford to incorporate with it all those necessary ingredients, such as soot, lime, burnt earth, and leaf-soil, to bring it into a fit state for cultivation. If these materials are procurable on easy terms, then a few inches laid on annually will in the course of a few years bring such a soil into a high state of cultivation; but the importance of deep stirring of such a soil as I am now treating upon; cannot be over-rated, especially if not well or naturally drained, as if there are no means of the surface water to get away below the roots of the ordinary subjects of a kitchen garden, the ground becomes soddened and sour, to say nothing of its being much colder than a well-drained spot during winter. This subject of deep as against shallow culture has long been a bone of contention amongst some of our best agriculturists; but an ordinary observer of the nature of the soil, and the purposes for which it is worked, can easily reconcile these apparent contradictions, as a deep rich soil can never be moved too much or too deep, for by deep culture rich earth is brought to the surface, air and water are more readily admitted, and the roots of plants are encouraged to spread more freely, as well as to penetrate deeper, while the rich soil affords an abundance of nourishment. But with a shallow soil, with a lower stratum of inferior quality, no good can result by bringing it to the top unless specially managed.

This brings me to say something on clay soils generally. For the convenience of working, these are the most undesirable soils which the gardener comes in contact with. But nevertheless they are valuable for the production of many kitchen garden crops, and with management they are more to be desired than some of those light soils resting on gravel. The greatest objection to a clay soil is that it is cold and ungenial for early spring crops, but its valuable properties in a dry, hot summer are so clearly demonstrated over those of a lighter and more open texture, that I would prefer to deal with it than with the latter.

The greatest consideration in bringing a new soil of this description into use as a kitchen garden, is to work out a thorough system of drainage, for by carrying away all unappropriated water the heat of the soil is increased, and it is consequently rendered more agreeable for vegetable life to feed in. This being done, the next important operation is to add to it such substances as will augment its fertility, and at the same time lighten its tenacious character. One of the essential conditions for securing early and fine vegetables is a warm friable soil. A light soil is of necessity better than a heavy one for an early spring garden; but for many summer crops I would not change a soil of a tenacious character for one that is composed of lighter or more friable substances. Therefore, the kitchen gardener will act wisely when he only aims at reclaiming a portion of his garden, just for spring crops, from that state in which he finds it. True, he may find that to improve the character of the staple of the whole garden may all require some attention, but I would only do it in part, and direct the chief attentions to the quarter that has the most likely appearance of producing the best and earliest crops for spring and early summer use.

For the common improvement of such land, there are many substances applicable. Both chalk and lime are valuable ingredients, the former keeping the soil more open, and retaining a great body of air, which is eminently beneficial, while lime also acts to some extent in the same manner. But the great advantage of lime over many other substances is its chemical action on the roots of plants which are left in the ground after the removal of a crop, as if put on the land and dug in fresh it soon causes a speedy decomposition of all organic matter it comes in contact with, thereby creating out of the soil an abundant supply of sustenance for the roots of the future crop to feed upon. To these substances may be added burnt earth, all the sweepings and clippings from the pleasure-ground, and indeed anything that will make it more precious and fertile, and always giving the preference to stable manure over any other. Here I must close my remarks on the subject of clay soils, and as soon as some other pressing matters which are waiting for space are off my hands, I hope to return to the consideration of other soils.

J. C. CLARKE.

NEW INVENTION FOR PLANT LABELS.—I have received samples of a newly invented plant label from an amateur who wishes to sell his invention, and who asks me to assist him. I would gladly write to a few firms, and state the case, and I might, perhaps, very quickly secure him a purchaser. But though I might do this solely for the benefit of a poor man, it would be equivalent to acting as an agent, and I therefore prefer to state the case here, and leave it to find attention where it may. The invention consists of a metallic label of most elegant appearance, on which the name in black and white can be changed *ad infinitum*, and the form of which can be adapted for walls, trees, flower pots—for in fact any purpose for which a label can be required. It would suit a manufacturer accustomed to small niceness in metal work, and I have no doubt at all that if introduced to public notice with spirit, the sale would be large and constant. Any letters respecting this that come to hand shall be forwarded to the inventor. It seems but proper to add that he expects only a small sum for his idea.

S. H.

PALMS FOR THE CONSERVATORY.

I see that, in some past issues of the GARDENER'S MAGAZINE, one of your able coadjutors has fixed the attention of the English gardener to some palms that have proved hardy in Britain. I am most glad, for everywhere I would wish to see the sublimest forms of vegetation adorning the green gardens of the noble English people. When I speak of these as "green gardens," I wish you to know my meaning much, for I have not seen such green gardens at home. In most parts of Germany we do not *eintauchen*, or as you say immerse our houses in woods of evergreen trees as you do; and our grass platz do not present such summer greenness in the depth of our hard winters, and our houses of the country look more cold and exposed to the blast, and the gardens have the wildness of the forest about them; but yours are rich and warm, and all comfort to the eye, as your hospitality of the inside is good to the heart. But my countrymen can show a warm house inside, though the fir-trees and the oaks be sullen without; and wherever beats a German heart, there is the power to melt ice, and to dissolve any frown, and make much gladness of the human life. Your green gardens strike me as one of the best features of the English scenery, and at this time of year I would but for the snow and the rain believe myself to be in the south of Europe, for nowhere else in the temperate zone is there so sweet a verdure in winter time as in England.

that need no stove, and can be kept with no more trouble than is required to keep a camellia. I call all such "conservatory palms," because the conservatory is always a "temperate house;" and when these palms acquire a good size, they are the most magnificent of all conservatory plants.

It is true that every palm, like every other plant, will thrive best by some peculiar treatment. Yet I will not attempt to refine on the minute treatment of each particular kind; for I will tell you that in the continental nurseries, where they are raised from seeds, and grown in quantities for the market, they are treated nearly all alike; some have more heat and more water than others, but the cultivators are not particular to distinguish amongst them, and yet most beautiful are the plants they produce. All the palms are treated as stove plants in the raising from seed, for we cannot afford to make them grow slow—it is cheaper to burn much fuel to have a quick growth; but we always harden them before they are sold, that they may not die through the cold of transit, and the check they suffer in being turned out of their pots. It is by observation of the process of hardening that we first learn the degrees of cold the species will bear, and I have tried all the kinds I could procure, and have, when they have become a few years old, kept them in cold houses all the winter, sometimes seeing a little rime on the edges of their leaves; and such as I shall name will bear this treatment well, and are therefore to be considered as world-

Latania Bourbonica.

But we shall leave the hardy palms to those able contributors who know so well how to treat upon them. Come with me into a house of the imagination, where I have grown thousands of palms, so that they could be packed in crates without pots, and sent to England to be sold at a few shillings each. I have just seen in the catalogue of Mr. Hooper, of Covent Garden, some palms announced, such as *Latania Bourbonica*, *Phoenix dactylifera*, and *Sabal Adansonii*, at less prices than your new pelargoniums and pansies attain, and I ask how it is that they are not sold in more thousands, for I would tell you that to produce them is not difficult. I have asked the English buyers why are they so timid as to take dozens when they should have thousands; and they say, "Our folks are afraid to buy them." Yes, I perceive that everywhere the idea of a palm tree carries with it the idea of a hothouse to keep it in, and a great furnace and elaborate hot-water system, and a great staff of gardeners. *This is all a mistake.* Many of the grandest palms of the whole world are perfect as specimens when only a few inches high; they may be purchased for a few shillings each, and they may be preserved through the winter in any good greenhouse which is protected from the attacks of frost. There are palms that need the stove, and the hardest kinds will grow fast and fine with much heat and moisture, but I repeat that I can find you some unsurpassed for beauty, that are perfect and picturesque when very small, that cost less than the commonest flowers, and

adapted plants, or shall I say plants that persons of taste of the middle rank of life may purchase with safety, and much enjoy for the embellishment of their gardens. While speaking of temperature, I would say that I have referred to a Dictionary which some English gardeners keep, and I find the directions given are the opposite of what experience teaches. The authors say in *Areca*, "all stove palms temp. in winter 55° to 65°." Now I can tell of *Areca*s that want only 35° to 45° in winter, and that will never hurt if not colder than 33°. Of *Chamædorea* they say, "winter 50° to 60°;" but I can show that there are four species in cultivation that will do well in common conservatory or greenhouse heat. I will not proceed, but will advise the practical man to observe for himself, and to take not much notice of garden dictionaries.

The soil for palms should be the most part fibrous loam of the best kind, with a good proportion of sand added, and it is advisable to put some small charcoal over one convex tile to drain the pots until the plants become large, and then a small pot should be inverted over the principal drainage in the large pot, and the space around be filled with broken tile, and over that a layer of charcoal. If potted with such care, and the soil is good loam full of elastic turf, very few palms need be re-potted more often than every second year, and some will do three years without repotting.

Most palms like plenty of light, and when they are growing

they require abundance of water. There are some exceptions, as, for example, that beautiful and nearly hardy palm *Chamærops humilis* should be nearly dry at all times, except in the height of summer. Another point to be noticed is that the degree of water must be proportioned to the degree of heat. When kept in cool houses all winter, they must have very little water. During cold weather, when the thermometer descends to a minimum, they must not have water at all. When they are growing freely, give them water daily, but do not drench them, for that washes the goodness out of the earth; give enough to wet the soil quite through, but not enough to make a stream through the pot. Some of the English gardeners would stare to observe with what care water is given in the great continental nurseries where plants are grown by thousands for the markets. Why at many of these places there is no water, speaking by comparison, yet they keep their plants alive and well by great economy and most careful distribution.

As to temperature, it is a good thing in the treatment of conservatory palms to give them a little extra heat when they begin to grow, so as to help out the expansion of the leaves, for a check at this time will sometimes result in a deformed growth. Just such a rise of the glass as is required for camellias and azaleas is what these will be benefited by when commencing growth. Then atmospheric moisture will be beneficial. But at all other times treat them as common greenhouse plants, and as for the winter temperature, let it range as nearly as possible at 45° never descending below 35°, and never rising above 50°. On bright sunny days, such as an English gardener just now told me was a "gushing day," I would give plenty of air, to prevent the house becoming too warm; but after the end of February it would be good to raise the temperature gently, and give them a start into growth, so that they would have a long summer to complete their periodical activities, and go to rest in good time for the winter.

I speak of these as "conservatory palms" because of their peculiar fitness for the conservatory, and their adaptability to cool treatment. But almost any of them, when small, are as well adapted for glass cases as the very finest ferns are. Indeed, I wonder our Editor has not made as good a feature of case palms as he has of ease ferns, and I will say that I have expected it of him. I have thought more than once, when looking over the splendid collection of palms in the nursery of Ambroise Verschaffelt, at Gand in Belgium, that if the wealthy English ladies who so much love elegant plants in their chambers would come here and select for themselves, every drawing-room would become a microcosm of the glories of the vegetable kingdom. And when by care these palms become too large for the cases, they could be taken to the greenhouse; and when too large for the greenhouse, they could go to the conservatory; and when of quite stately dimensions, they could be put out on the grass all the summer for the "sub-tropical" embellishment of the English garden. I think I have said enough for this time, and now I will give a list of such palms as I have grown for many years by cool treatment, and I shall sum up their culture by saying, Whoso can grow a camellia, can also grow one of these, or all of these.

Areca Bauerii, *A. monostachya*, *A. sapida*.—These are species of the "cabbage palm." Others of this genus must be kept in the stove, and for those who can grow stove palms there are not two finer to be found than *A. speciosa* and *A. Verschaffeltii*.

Brahea calcarea, *B. dulcis*, *B. nobilis*.—These are beautiful Mexican palms, with large fan-like leaves most elegantly disposed at the summit. They are very hardy.

Chamædorea atrovirens, *C. elegans*, *C. Ernesta-Augusti*, *C. Verschaffeltiana*.—I will guarantee all these to thrive by cool treatment, though where I have yet seen them in England they are always kept as if they would die if not always quite hot. They ought to have a rich soil and abundance of water when growing. These are quickly propagated by suckers from the root.

Chamærops excelsa vera (Van Siebold), *C. Ghiesbreghtii*, *C. nitida*, *C. sinensis*, *C. tomentosa*, *C. humilis*, *C. Fortunei*.—These fine fan palms are all nearly hardy, and the last two quite so. They may all be increased by means of suckers, though seeds are generally plentiful. The beautiful *C. Stauracantha* requires the stove.

Cocos Australis, *C. campestris*.—These are two of the grandest palms in cultivation; they are splendid to put out in the garden during the summer.

Corypha Australis.—This fan-palm, of New Holland, desires a sandy soil. It is most largely grown on the Continent, and is well adapted to place on the dinner-table—a subject I quite forgot when speaking of the uses of conservatory palms.

Lantana Bourbonica.—This is the hardiest of all the *Lantania*s, and I present a portrait of a plant of my own which is twenty years of age, and has never been in any better place than a cool house for fifteen years past, and I have seen hoar frost on the edges of its leaves. What beauty it has! and how well adapted is it to place out in the garden all the summer! This may be purchased by the thousand at the great nurseries I have already spoken of.

Phoenix humilis, *P. leonensis*, *P. reclinata*, *P. dactylifera*.—These are the hardiest species of date-palm, which your books say require a stove, but which I say from experience do not need other than such as you call greenhouse treatment. The East Indian species of *Phoenix* do indeed require the stove, and must have it; but we must make distinctions when we find such plants as I have named well able to bear a low temperature.

Sabal Adansonii, *S. longifolia*, *S. princeps*.—The first-named of these is one of the cheapest and finest palms in cultivation. It is adapted for the dinner-table, the glass case, the window, the greenhouse, or for the open garden during the summer.

Seaforthia elegans, *S. robusta*.—These I have well proved to be quite hardy as compared with the generality of palms. The second of them is a grand palm, and should be seen in every choice conservatory.

Thrinax parviflora, *T. tunicata*.—These are the only species of this group that I would keep in a cool-house. I killed many fine specimens in a trial of them all I made four years ago. We must kill sometimes to learn, but it grieved me much, and I might have saved my plants if I had not been determined to see the whole issue of the experiment. Indeed, I had faith they would all bear the cool treatment. However, these two are safe, and I strongly recommend them.

This closes the list, which perhaps after the present winter is past I shall be able to enlarge, for I have some more palms under trial. I would only say, in conclusion, to the lover of fine plants, you may order of your nurserymen all that I have named; they will not cost much—not one need cost more than fifty shillings, and many of them may be had for less than five shillings each. May the New Year bring to our readers the sense of a life nobler than the events which colour it, and a hope that is akin to the emblem of the palm tree, which of old was the type of immortal pleasure. Such is the wish of the writer of these lines.

KARL PROSPER.

A FEW WEEKS IN NORTH WALES.

RHUG HALL, THE RESIDENCE OF W. WAGSTAFF, ESQ.

The mansion is in a beautiful park on the south side of a ridge of mountains which commands most delightful prospects over the most exquisite landscapes the eye ever beheld, richly varied with wood, rock, and pasture. Rhug Hall was for centuries the family seat of the Vaughans. Eight years ago the late Sir Robert Vaughan died without issue. The estate was left to the Honourable C. Wynne, the second son of Lord Newborough. There are fifteen thousand acres belonging to this estate, the greater part fertile land, and in a high state of cultivation. It lies between Llangollen and Bala. It is remarkable as anciently being the property of the celebrated Welsh hero Owain Glyndwr (known in story as Owen Glendower). He was the son of Griffith Vyehan, which is the ancient name for Vaughan. This is the hero whose actions make so conspicuous a figure in English history, and who appears in Shakespeare's *Henry IV.*, Part I., as the most dreaded enemy of the house of Lancaster. At the opening of the story, King Henry says, in reply to Percy's description of the bloody conflict between Owen and Mortimer—

He never did encounter with Glendower;
I tell thee,
He durst as well have met the devil alone,
As Owen Glendower for an enemy. (Act i. scene 3.)

In the third act, where Owen declares—

At my nativity
The front of heaven was full of fiery shapes,
Of burning cressets; and at my birth,
The frame and huge foundation of the earth
Shak'd like a coward;

and receives from Percy the sarcastic rebuke which follows, we see Owen established upon these mountains by the authority of the Church; and I may therefore properly quote the passage which immediately connects the hero with the scene before me:—

Glendower. Come, here's the map; shall we divide our right
According to our threefold order taken?

Mortimer. The archdeacon hath divided it
Into three limits, very equally:
England, from Trent to Severn, hitherto,
By south and east, is to my part assigned:
All westward, Wales beyond the Severn shore,
And all the fertile land within that bound,
To Owen Glendower. And, dear coz [to Hotspur], to you
The remnant northward, lying off from Trent.
And our indentures tripartite are drawn,
Which being sealed interchangeably
(A business that this night may execute),
To-morrow, cousin Percy, you and I,
And my good lord of Worcester, will set forth
To meet your father, and the Scottish power,
As is appointed us, at Shrewsbury.
My father, Glendower, is not ready yet,
Nor shall we need his help these fourteen days;
Within that space [to Glendower] you may have drawn together
Your tenants, friends, and neighbouring gentlemen.

(Act iii. scene 1.)

The view from the hills is extensive, commanding forty square miles of picturesque and highly romantic scenery, and justly celebrated as being the loveliest spot in North Wales. Near the summit of one of the hills, called Cefyn Creini, or "Mountain of Worship," there is a vast circle of stones, which bears the appearance of having once been a fortification. It is nearly half a mile in circumference, and at a distance looks like a huge Druidical circle, though of later origin than the time of the Druids. On another hill there is a heap of scattered stones on a mound, surrounded by a moat. These ruins are supposed to be the remains of Owen Glendower's palace. On another of the hills there is a pool, with an island about ten yards over, and a willow tree growing on it. When the wind blows hard, its force against the tree is sufficient to move the island, which floats from one side of the pool to the other. It reminded me of the floating islands which

have occasionally occurred in the lakes of Cumberland. On my way to the Hall, I was particularly struck with the admirable harmonizing of the plantations, with the various alternations of hill and dale. They are not thin or scattered about without any meaning, but richly massed and grouped, breaking occasionally into open spaces adorned with single trees, blended together in one broad connected whole. The varied tints that autumn could afford seemed to me to have been studied before the planting took place, and added greatly to the effect. The green of oaks and firs, all the different hues of the ash, the elm, the heech, and the horse-chestnut, mingled together, and produced a harmonizing effect, which the breadth of light and shadow softened into mellowness, showing many points of excellence which were very effective and pleasing to the eye. The Hall, at a distance half hidden by trees, forms an essential part of the view. There are two other buildings appearing among the trees: they are an elegant chapel, and a block of almshouses for the aged poor. The mountains in the background add to the scenery an additional charm—they, in fact, render sublime that which without them would be beautiful. As you draw nearer, the Hall is quite hidden among the trees, and by whatever gate you enter the park, you have to walk some distance before you can catch a glimpse of the mansion.* I found it rather a formal-looking building, not at all picturesque when near. In the noble park, the stately and venerable oaks spread their arms over the ground as if to shelter an army. Some of the oaks are most gigantic; one measured 47 feet in girth of trunk, and its magnitude was as nothing compared with its picturesque beauty. There are many magnificent elms, which give the place an ancestral air. The ornamental waters, islands, rustic bridges, shady banks, waterfalls, are variously displayed or partially concealed from the eye of the observer by thickets. Close beside the mansion is the flower-garden, clad in lively colours, and giving to the whole a considerable degree of elegance, beauty, and grandeur.

Fields, lawns, hills, pastures, all appear
Clad in the varied beauties of the year;
Meandering waters, waving woods, are seen,
And cattle scattered in each distant green.

Near the house, picturesque beauty was not sacrificed by the prevailing fashion of cutting every available space into hearts, kidneys, diamonds, and rolypolys; but comfort, neatness, elegance, and variety had been studied and achieved. There were good and convenient gravel walks, grass turf in the finest order, and planted with subjects that are beautiful the whole year round. There were flowers sufficient to give variety and spirit without causing satiety in summer, or their absence causing a blank in winter. It was a good landscape, and all parts free and unconstrained by any prominent and highly illuminated spot which could affect the harmony of the whole, and destroy the peculiar characteristic beauties that raise our admiration. I hope it will not be supposed that by my admiring the picturesque, I have no taste for flowers, or would undervalue the symmetry and beauty of the display I saw here. I think flowers are the most delicate and charming of all inanimate objects, particularly when growing in the open air, and their colours harmonizing perfectly with the green turf. But their position must be studied if the landscape is extensive and picturesque, as it is at Rhug. If strong brilliant colours are in the foreground, they arrest and irritate the eye, and prevent a happy blending or combination of the several features of a scene. I have frequently seen charming little views completely spoiled by being too highly coloured; and if the glare and grandeur were taken away, the soft colours would blend and connect into a sweet united whole. Then the eye would dwell upon the scene with pleasure, and after the first enchantment would return again and again with a new source of delight. The flower garden lies to the right of the house, and is visible from the terrace. A piece of ornamental water divides it from the park, and it is a model of simplicity, the grouping of the beds artistic, and the flowers in the sweetest harmony. Though a high degree of brilliancy was diffused over the whole of the beds, the colours were well balanced. The water gave a peculiar freshness to the whole. The beautiful and varied effects produced by the near objects, too, were very pleasing—the trees and bushes immediately on the bank casting their shadows with great depth and breadth; the turf seemed more soft and smooth; the flowers were reflected in the mirror, and their colours assumed a mellowness possible only when water lends its valuable aid. After the stream has passed the dressed and decorated part of the ground, it loses its calm, clear surface, and becomes an irregular, rapid, and strong torrent, plunging at last over a ledge of rock, and making a fine cataract. Its wildness where it is hemmed in between rough rocky heights, affords a fine example of the picturesque as contrasted with the beautiful it exemplifies where it skirts the flower garden.

The Rosery is a long bank or border running down one side of the lawn opposite the water; this was extremely well done; it showed a high degree of polish. I understood from Mr. Elcom, the intelligent gardener, that the lady was at home in this department; and I think by the way these roses were grouped and combined, and the several varieties contrasted, the rosery could not be anything less than the principle feature in the garden. The trees were of different ages and sizes, planted at different distances from each other; the outlines full of variety—some on their own roots, and others on the brier—some advancing forwards, and others retiring to the rear, making a picture rather than a plantation: yes, a picture painted with roses. This border, when in full bloom, must present a charming appearance. At the farthest end of the garden a great belt of hollyhocks had a very striking effect; they had a fine military character, all as straight and as upright as a troop of soldiers on parade; not a straggler was to be seen. Strong wires, almost invisible, were stretched along the border, four wires to a row, and so the whole row was tied to the same wire; by this method the plants have a neat appearance, and occasion less trouble than by the use of stakes. The gardener gives Mrs. Wagstaff the credit for this plan. There were several beds of fuchsias; the ground was covered with dwarf plants, from amidst which arose standards of magnificent dimensions, some of them 8 feet high. The verbenas are not banished from these gardens, and it was quite refreshing to see so many old favourites blooming away, their soft delicate colours without spot or blemish. There were no signs of disease here to bring them into disrepute as in England. I was particularly struck by the delicate green of the lawn; it was made from the turf of the mountain, and kept in order by one of Green's pony machines. The machine cuts 3 feet; it cost £16. It has been in use seven years, and is as good now as it was when new: so the gardener says; I suppose he means it does its work as well.

The kitchen garden was everything a good gardener could require. Mr. Elcom did not take any credit to himself; he said it was good ground, good walls, plenty of manure, plenty of help; all he had to do was to see it was deep dug and not scratched over. He took me to see his carrots, onions, broccoli, and late peas. "There," said he; "while the family get such vegetables as those, I think I shall not hear any grumbling;" and I thought so too. The wall-trees were pictures of health—the peaches and nectarines especially. He spurs most of the shoots except the leaders, for he finds that he gets more fruit by this plan than leaving the shoots at full length. I was next conducted through the plant houses in the ornamental foliage department, and saw plenty of ferns. The principal subjects were begonias, achimenes, crotons, cyperus, dracenas, coleus, gesnerias, justicias, cissus, and caladiums. There was a capital plant of hemanthus, and a nice lot of amaryllis. In the hard-wooded house, camellias and azaleas appeared to be the leading features. I thought the gardener seemed to hurry me through those houses, and in fact was ready to go out before I could get half-way in. I could not make it out, for everything in the houses appeared clean and skilfully managed; but I soon found out he had something else to show me which he wanted me to see in broad daylight: he wanted to show me his cucumbers, melons, and grapes. But before I go any further I must say Mr. Elcom is one of Frost's men from Preston Hall, the well-known fruit grower and shower, and he would naturally take delight in fruit growing; and he is very successful in cucumbers and melons. He makes one house suffice for both these subjects; at one end cucumbers were planted, and at the other melons were grown in pots. Mr. Elcom speaks very highly of "Cuthill's All the Year Round" cucumber; certainly I saw very handsome fruit. Turner's Gem and Beechwood melons are also great favourites here. At last we went to the vinery, and I believe if I had listened to all Mr. Elcom could say about grapes, I might have been there now. The house contained principally Black Hamburgs, but there were a few vines of Black Prince, and at the warm end Barharossa, Muscat of Alexandria, and Canon Hall. There was nothing extraordinary in the size of bunches, but I never saw such large berries. I measured one; it was three inches and three-eighths in circumference, well coloured, a blue-black, the skin thick, the flesh firm and sweet. I believe this to be Meredith's true Black Alicante. In our conversation he said he was pleased with the remarks made about grapes by Mr. Clarke in the magazine. He quite approves of all Mr. Clarke says on grape growing; and I was to tell Mr. Clarke, if I saw him when I returned to London, that if his rambles should bring him to Wales, as mine had brought me, he was to call at Rhug; he would leave it to me to tell him how he would be treated, for he would fare as I had done. All I can say is that I spent a happy day, and am very grateful for the kindness shown me, and also for the information I received from the intelligent gardener, particularly on grape growing.

N. COLE.

Calendar.

WORK FOR WEEK COMMENCING JANUARY 7TH.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN will now want a little extra labour to clear off remains of winter crops that have ceased to be profitable, and dig and dung the ground for summer vegetables. Manuring may now be proceeded with, and breadths may be marked out and got ready for sowing as soon as weather permits. Sow peas, beans, round spinach, parsnip, horn carrot, saladings, and a few sorts of cabbage.

ASPARAGUS PLANTATIONS to be marked out at once, and the ground dug two spits deep. A light sandy loam is the best soil for asparagus, but a soil almost wholly sand will be better than one wholly clay, because when heavily manured, the sand will suit it admirably, but without plenty of manure will be useless. In a deep fertile loam a moderately heavy manuring will suffice, and the manure should be well mixed with the staple at least two feet deep. In any case the piece must be thoroughly well drained. If asparagus must be grown on a clay land, lay on six inches of sand or coal-ashes, and dig this in to a depth of two feet, mixing it well with the soil, and let the ground rest a fortnight, and then dig again and liberally manure. If it is intended merely to sow for transplanting, a good manuring one full spade deep will suffice, if the second spit was previously stirred at a winter digging.

CABBAGE of all kinds may be sown on a warm border. The most useful to sow now are Shilling's Queen, Early York, and Rosette Colewort.

CAULIFLOWERS are apt to die off now unless kept dry; a little peat will be useful to sprinkle amongst them where they are suffering from damp. Dry sand and wood-ashes may be used for the same object. If the plants are crowded, they will only kill each other, so thin at once if necessary.

CUCUMBERS managed as advised in the calendars of the last few weeks will now be coming forward for hedging out. They should be kept in the house till they have filled 48-sized pots with roots, and then be planted. If kept any length of time starving in a pot-bound state, they will become infested with red spider, and weakened in constitution. When ready to plant out, the bed should be in a sweet condition through occasional forking over the dung. The bed is to be made by laying some strips of turf grass side downwards in the centre of each light; on this put three or four bushels of soil in a heap, consisting of loam from rotted turves one part, leaf-mould one part, and dung rotted to powder one part. The third day after putting on the soil, put the bulb of a thermometer into the hillock, and if it registers 70° to 80° plant at once; if higher than 80°, wait a few days longer. A fair average to start with is 75°. Plant in the centre of the hillock, and peg down the runners regularly, and shut close. In the course of a few days give air cautiously, to let off any rank steam, and sprinkle the leaves frequently, but give only just enough water at the root to keep the soil moist until the plants have made a start. Choice sorts may be kept on from cuttings, to avoid the risk of deterioration. Plants that have been in fruit during the winter will furnish cuttings for succession, if the sorts are approved of for the purpose. Give air to plants in frames as often as the weather will permit. During mild weather a little air may be left on all night, with a mat over the opening to prevent too cold a draught.

DRAINING.—This is a good time to make and repair drains. Drains 4 feet deep and 20 feet apart will serve almost anywhere to carry off excess of rainfall quickly; and the best drain tiles are those made tunnel-fashion

—that is, a half pipe and flat sole. The drains should be cut by a man skilled in earth-work, to make sure of a hard bottom and a regular fall to the outlet; if anywhere cut with holes or depressions, it will be no easy matter to level these solid again, to prevent a sinking of the drains at those places; in fact, not a crumb too much should be taken out anywhere. When the pipes are laid, place six inches of hard rubbish, such as brick-bats, broken crocks, tiles, chalk, &c., over them, and fill in. Such drains will last a lifetime. Nothing to equal chalk for filling in over drain-pipes.

MELONS AND CUCUMBERS in the forcing-pit to be kept carefully trained about nine inches from the glass, to be regularly stopped, and at a temperature of 70° by day and 60° by night. Sow now for plants to bed out in frames and pits, and for succession in the early forcing house.

PARSNIPS to be sown at once for the main crop. Choose a quarter well manured last summer, and that has been laid up all winter. The Hollow Crown is the most useful variety, but in deep, sandy, rich soils, the Guernsey parsnip grows to an immense size. Sutton's Student parsnip is the best flavoured and most even parsnip grown.

SOW IN HEAT Tomatoes, Capsicums, Egg Plants, Cocksoombs, Amaranthus, and Intermediate Stocks.

Flower Garden.

BEDDING PLANTS must now be thought of, quantities of the several kinds determined, and hotbeds made up for starting old plants for cuttings, and for the first batch of plants required early. Old Verbenas, Petunias, Cupheas, Enocheras, Tropaeolums, &c., may be put into a steady heat at once to furnish young shoots for propagating, and seeds may be sown of *Lobelia erinus speciosa*, if to be raised from seed, by which means it comes pretty true.

ROSES required to bloom early should be pruned now, but it is too early to prune the general collections.

RANUNCULUS BEDS.—It is becoming customary now to plant the ranunculus in February; November used to be the month, and in situations not subject to severe spring frosts November and December may still be considered the best times for planting. Not that the flowers are finer—they are simply earlier; and for this gain there is occasionally a risk of losses through frost. The bed ought to be prepared a full month at least before planting, to give it time to settle and become firm, for failure is certain if the soil lies light and spongy. For February planting, the bed ought to be ready early in January, and the best time for planting is between the 1st and 20th of February, the precise day or week being determined by the weather. There has been a good deal of discussion as to the proper planting season, but it is now pretty generally agreed that autumn planting is attended with risk, for which early blooming is the only compensation, and that the first twenty days of February are the safest for collections of any value. In cold, wet, and very tenacious soils, or in exposed situations, it would even be better to defer planting to the first week in March, and planting may be the more safely deferred with the ranunculus than with most other tubers, for they retain their vitality out of the ground two or three years, and if kept cool and dry suffer but little exhaustion by delay. The proper soil is a rich mellow loam, the proper manure well-rotted cow or horse-dung; recent manure ruins it; so do any exciting compounds of night-soil, blood, or chemical stimulants, or excessive quantities of manure of any kind, all of which have been recommended in bewildering numbers, and the proportions stated with ridiculous precision. If the soil of the garden is at all suitable, manure it well in preference to preparing composts; if it is not of a loamy and somewhat crumbly character, procure the top spit of an old pasture—one in which buttercups abound is best; ridge this up, turn it occasionally for six months or more, and with this and well-rotted dung prepare your bed.

HARDY PLANTS IN FLOWER.—*Tussilago fragrans*, *Primula vulgaris*, *Hepatica triloba*, *Bellis perennis*, *Helleborus niger*, *Cheiranthus alpinus*, *Stellaria holostea*, *Eranthis hyemalis*. *Frame*: Snowdrops, Crocuses, Tulips, Hyacinths, Russian and Neapolitan Violets.

Fruit Garden and Orchard House.

FRUIT TREES not yet pruned will suffer if not speedily attended to. Save any scions wanted for grafting by heeling them in at the foot of the tree they are taken from. They will take all the better for being cut some time before grafting. Fruit quarters that have been neglected hitherto must be dressed, cleaned, trained, and put in order at once. Make ready protecting material for wall trees, for we may expect sharp weather just as the blooms expand, when the wind usually sets in from the east.

FRUITS IN SEASON.—*Apples*: Alfriston, K., Adams's Pearmain, D., Beauty of Kent, K., Bedfordshire Foundling, K., Bess Pool, D., Blenheim Orange, K., Braddick's Nonpareil, D., White Calville, K., Cockle Pippin, D., Cornish Gilliflower, D., Cox's Orange Pippin, D., Dutch Mignonne, Golden Pippin, New Hawthornden, K., Hughes's Golden Pippin, D., Lamb Abbey Pearmain, D., Lemon Pippin, K., Mannington's Pearmain, D., Newtown Pippin, D., Nonpareil, D., Northern Spy, D., Ord's, D., Ribston Pippin, D., Sam Young, D., Stamford Pippin, D., Winter Pearmain, K. *Grapes*: Barbarossa, Black Hamburg, Black St. Peter's, Calabrian Raisin, Kempsey Alicante, Lady Downe's Seedling, Trentham Black. *Pears*: Alexandre Bivort, Alexandre Lambre, Angélique de Bordeaux, Beurré d'Aremberg, Beurré Duhaime, Beurré Langelier, Beurré Sterckman's, Bezi Vaet, Broompark, Chaumontel, Colmar, Conseiller de la Cour, Doyenné Goubault, Forelle, General Todleben, Huyshe's Bergamot, Ne Plus Meuris, Winter Nelis, Zephirin Gregoire.

PEACHES in forcing-house require much care; the sir of the house to be rather drier as the trees come into bloom; and to prevent red spider, a little vapour to be caused by sprinkling the paths every evening. The pollen is usually active during the midday hours, and it is then that a dry air is most important, and as much ventilation should be admitted as the state of the weather will allow.

STRAWBERRIES in the forcing-house will swell their fruit grandly if the pots are placed in pans filled with fresh dung and kept always wet; the dung to be renewed every ten days. As soon as the roots find it, the vigour of the plants will be increased wonderfully. If plunged in a dung-bed, they will require very little watering at present.

ORCHARD-HOUSE.—Keep the house shut during cold and stormy weather. To prevent injury of the roots of the trees by frost, sprinkle dry hay amongst and over the pots to a depth of six inches above the roots of the trees. During the bright weather open the ventilators and give water. The object of the cultivator should be to keep the trees safe and still. Frost will harm them if severe, and the roots are unprotected; and mild sunny weather will start them into growth prematurely if they are not

well ventilated. At the first opportunity paint the trees with a solution of "Aphis wash," prepared by the City Soap Company; it not only destroys the brown aphid which infests peach trees, but also scale, and every other pest capable of lodging in the bark.

Greenhouse and Conservatory.

GREENHOUSE to be kept as airy as possible, without giving a chill to any delicate subjects. Clean glass is a great help now to the well-doing of the plants. Hard-wooded plants must never be subjected to sudden extremes of temperature; soft-wooded plants bear heat much better, but a great heat is never required, and is always injurious. Do not allow any plants to become dust-dry at the root; even during frosty weather, give water when required, and maintain a genial temperature of 50° to 60° by day, and 40° by night.

GREENHOUSE PLANTS IN BLOOM.—*Dentzia gracilis*, Tree Carnations, Camellias, *Hovea Manglesii*, *Andersonia Sprengeloides*, *Correa speciosa*, *Correa pulchella*, *Correa platycentra*, *Cytisus racemosus*, *Cyclamens*, Chinese Primulas, *Epacris rubra*, *Epacris maxima*, *Diphne rubra*, *Jasminum ligustrifolium*, *Jasminum nudiflorum*. *Ericas*: *blanda*, *colorans*, *scabriuscula*, *sebana*, *regerminians*, *pulchella*, *aspera*, *caffra*, *denticulata*, *vernix*, *vestita*, *tenella*, *decora*, *handoniana*, *carinata*, *exsurgens*, *flava*, *Lambertiana*, *formosa*, *longipedunculata*, *imbricata*, *ignescens*, *mammosa*, *ovalifolia*, *mutabilis*.

ERICAS to be kept cool and airy, and fire-heat used only when necessary to keep out frost.

FUCHSIAS for early bloom and exhibition will now require a little extra attention. Shake them out of their pots and repot in turfy loam, leaf-mould, and peat, in as small pots as possible, but their roots are not to be hacked about in order to get them into very small pots. When potted, give them a moist heat of 65°, and give them a shift as soon as they have filled their pots with roots. Never stop and shift at the same time; the best practice is to stop first and wait till new shoots break; then shift, and so on till they are in blooming pots. Plants kept to cut from need not be shifted; start them at once as they are in a temperature of 60° to 65°, and take cuttings as soon as the shoots are one or two inches long; these will root immediately in sand with good bottom-heat.

PELARGONIUMS.—Shift specimens into their blooming pots, give a slight rise in the temperature, and keep near the glass.

AZALEAS AND CAMELLIAS claim attention now that we have little else to depend upon to keep the conservatory gay. A little pains now bestowed in training and disbudding will repay, and Camellias are so heavily set with buds that generally speaking it would be most unwise to allow all to remain. We have seen lately bushels of buds removed in some places where a moderate show of fine flowers is preferred to a mass of indifferent ones, the profusion of which will weaken the plants. Azaleas coming into bloom must be kept at a regular temperature, and have plenty of water. Beware of urging them too rapidly, and place none in the stove until they have been first gently stimulated by the warmth of an intermediate house. Plants in flower will require a night temperature of 50°, to rise to 60° and 65° by day. Those for late blooming should have a temperature not lower than 40° by night, and as much ventilation as the weather permits.

CLIMBERS in greenhouses may now have special attention to reduce their dimensions. Lay in wood for next summer's bloom, and clear the walls and trellises.

Stove and Orchard House.

ORCHIDS IN BLOOM.—*Angræcum superbum*, *Angræcum virens*, *Dendrobium speciosum*, *Burlingtonia amœna*, *Dendrobium chrysotoxum*, *Barkeria elegans*, *Cymbidium elegans*, *Cælogyne Gardneriana*, *Cælogyne speciosa*, *Limatodes rosea*, *Bletia campanulata*, *Calanthe vestita*, *Cypripedium insigne*.

ACHIMENES to be started in pans preparatory to potting off singly; soil, equal parts peat, leaf-mould, and sandy loam.

GLOXINIAs.—Start a few by first potting in fresh soil, consisting of loam, peat, and leaf equal parts. Put in bottom-heat at once.

Selections for the Year.

A SELECTION OF USEFUL FRUITS.

APPLES FOR ORCHARD PLANTING.—Alfriston, Bedfordshire Foundling, Bess Pool, Blenheim Orange, Court of Wick, Dumelow's Seedling, Devonshire Quarrenden, Dutch Codlin, Fearn's Pippin, Forge, French Crab, Golden Noble, Gooseberry Pippin, Hawthornden, Hanwell Souring, Kerry Pippin, London Pippin, Nonpareil, Norfolk Bearer, Northern Greening, Summer Pippin, Syke House Russet, Winter Pearmain, Yorkshire Greening, Waltham Abbey Seedling.

APPLES (DESSERT) FOR GROWING AS PYRAMIDS AND BUSHES.—Ashmead's Kernel, Beauty of Kent, Braddick's Nonpareil, Cellini, Cornish Gilliflower, Cox's Orange Pippin, Court Penduplat, Early Harvest, Early Nonpareil, Knight's Downton Pippin, Golden Harvey, Juneating, Hubbard's Pearmain, Irish Peach, Mother, Newtown Pippin, Manx Codlin, Lord Suffield, Nonesuch, Northern Spy, Reinette du Canada, Ribston Pippin.

APPLES FOR VERY EXPOSED SITUATIONS.—Carlisle Codlin, K.; Devonshire Quarrenden, D.; Early Julien, D.; Franklin's Golden Pippin; French Crab, K.; Hawthornden, K.; Kerry Pippin, D.; Keswick Codlin, K.; London Pippin, K.; Manx Codlin, K.; Nonesuch, D.; Summer Strawberry, D.; Tower of Ghamis, Winter Strawberry, D.; Winter Coleman, K.; Yorkshire Greening, K.

CHERRIES FOR GARDENS, BEST TWELVE.—Early Purple Gean, D.; Belle d'Orleans, D.; Black Tartarian, D.; May Duke, D.; Black Eagle, D.; Monstrous Heart, D.; Bigarreau, D.; Florence, D.; Coe's Late Carnation, D.; Kentish, K.; Belle Magnifique, K.; Morello, K.

CHERRIES FOR ORCHARDS.—Early Prolific, Black Tartarian, May Duke, Elton, Büttner's Black, Kentish Bigarreau, Mammoth, Late Duke, Tecumseh.

CURRENTS.—*White*: White Dutch. *Red*: Cherry, Raby Castle, Red Dutch. *Black*: Ogden's Black, Black Naples.

FIGS FOR WALLS.—Black Genoa, Black Ischia, Brown Turkey, Marseilles, *For Forcing*: Black Ischia, Brown Ischia, White Ischia, Pregussata, Castle Kennedy.

GOOSEBERRIES FOR DESSERT.—*Red*: Keen's Seedling, Red Globe, Rough Red, Turkey Red, Companion. *Yellow*: Glory of Ratcliff, Rumbullion, Leader, Yellow Champagne. *Green*: Green Gage, Green Gascoigne, Turn-out, Hebburn Prolific. *White*: White Eagle, Queen of Trumps, Bright Venus, Hedgehog, Whitesmith, White Champagne.

GRAPES FOR WALLS.—July Muscat, Muscat [St. Laurent, Esperione, Miller's Burgundy, Pitmaston Cluster, Royal Muscadine, Black Hamburg, Chassolas Musqué. The last two require dry borders and good positions, or they will not ripen their fruit.

GRAPES FOR GROUND VINERIES.—Black Prince, Black Hamburg, Black Frontignan, Grovond Sweetwater, Buckland Sweetwater.

GRAPES FOR COOL VINERIES.—Royal Vineyard, Madeira Muscat, Black Champion, Black Hamburg, Golden Hamburg, Buckland Sweetwater.

GRAPES FOR HEATED VINERIES.—Muscat of Alexandria, Bowood Muscat, Canon Hall Muscat, Meredith's Alicante, Muscat Hamburg, Barbarossa, Lady Downe's Seedling.

NECTARINES FOR WALLS.—Balgowan, Early Newington, Elruge, Hardwicke, Rivers's Orange, Red Roman, Large White.

PEACHES FOR WALLS.—Small Mignonne, Early York, Early Grosse Mignonne, Crawford's Early, Royal George, Noblesse, Barrington, Walburton Admirable, Salway.

PEARS, THIRTY FOR GROWING AS BUSHES AND PYRAMIDS.—Alex. Lambre, Bergamotte d'Espere, Beurré Clairgeau, Beurré d'Aremberg, Beurré d'Amanlis, Beurré de Rance, Eastern Beurré, Beurré Goubault, Beurré Superfin, Bon Chretien, Broom Park, Conseiller de la Cour, Dalices de Jodoigne, Doyenné Boussoch, Doyenné Defais, Doyenne d'Été, Duchesse d'Angouleme, Eyewood, Fondante d'Autunne, Forelle, Glou Morceau, Huyshe's Victoria, Jargonelle, Louise Bonne of Jersey, Monarch, Prince Albert, Suffolk Thorn, Winter Nelis, Yat, Zepherin Gregoire.

PEARS, TWELVE VERY CHOICE FOR A SMALL GARDEN (hardy).—Graham's Autumn Nelis, Glou Morceau, Jargonelle, Winter Nelis, Josephine de Malines, Easter Beurré, Doyenné d'Été, Bon Chretien, Louise Bonne of Jersey, Beurré Rance, Alexandre Lambre, Duchesse d'Angouleme.

PLUMS FOR DESSERT.—July Green Gage (*wall*), Denniston's Superb, Perdrigon Violet Hatif, Green Gage (*wall*), Transparent Gage, Jefferson, Coe's Golden Drop (*wall*), Reine Claude de Bayay, Coe's Late Red, Blue Imperatrice (*wall*).

PLUMS FOR CULINARY PURPOSES.—Early Prolific, Early Orleans, Goliath, Victoria, Diamond, Washington, Belle de Septembre.

RASPBERRIES.—*Yellow:* Yellow Antwerp, Magnum Bonum, October Yellow. *Red:* Fastoff, Beehive, Prince of Wales, Red Antwerp.

STRAWBERRIES, TWELVE BEST.—Black Prince, Sir Joseph Paxton, Carolina Superba, La Constante, Elton Pine, Keen's Seedling, Rivers's Eliza, Oscar, President, Ingram's Prince of Wales, Stirling Castle Pine, Frogmore Late Pine.

A SELECTION OF THE MOST USEFUL VEGETABLES.

BEEF.—Pine-apple, St. Osyth, and Dewar's Short-top are the three best. The Seakale beet is rubbish.

BRUSSELS SPROUTS.—Rosebery and Scrymger's Giant.

BEANS.—Mazagan, Minster Giant, Longpod, Taylor's Broad Windsor, Green Windsor.

KIDNEY BEANS.—*Dwarf:* Perkin's Early Warwick, Sion House, Early Six Weeks, Newington Wonder, Flageolet. *Runners:* Scarlet, Eclipse.

BORECOLE (or KALE).—Cottagers, Green Curled Scotch, Solater's New Cabbage, Albert Sprouts, Fearnought.

BROCCOLI.—*To cut in December, January, and February:* Snow's Winter White, Early Penzance, Adams's Early White, Hampton Court, Dalmeny Park, Dilcock's Bride. *To cut in May and June:* Conning's Reliance, Foster's Champion, Richmond Late, Miller's Dwarf, Basket White, Cattell's Eclipse. *For cutting in September, October, and November:* Walcheren, Dancer's Pink Cape, Grainger's White, White Cape.

CARROT.—*For gardens:* Long Surrey, Intermediate, French Shorthorn. *For farm and allotment grounds:* Belgian White, Belgian Yellow, Selected Altringham.

CABBAGE.—Kemp's Incomparable, Tom Thumb, Brunswick, Sutton's Imperial, Rosette Collard, Enfield Market, Dwarf Early York, Atkinson's Matchless, Green Curled Savoy, Early White Savoy.

CAULIFLOWER.—Stadtholder, New Mammoth, London White, Walcheren, Late German, Le Normands.

CUCUMBER.—Hamilton's Volunteer, Kirklees Hall Defiance, Swadling's Berkshire Challenge, Carter's Champion, Cuthill's Black Spine, Lord Kenyon's Favourite, Mill's Jewess.

* * * Usually Black-spined cucumbers are most handsome, but less in size and productiveness than white-spined kinds.

CELERY.—Sutton's Superb Pink, Cole's Dwarf Red, Incomparable White.

ENDIVE.—Green Curled, Batavian, Moss Curled.

LETTUCE.—Berkshire Brown Cos, Sutton's White Cos, Black-seeded Bath Cos, Tom Thumb, Vosey's Nonesuch Cabbage, Ne Plus Ultra Cabbage, Hammersmith Cabbage.

ONION.—Reading, White Globe, James's Keeping, Globe Tripoli, Deptford, Nuneham Park.

PEAS.—*First Early:* Sutton's Ringleader, Sangster's No. 1, Early Emperor. *Second Early:* Eley's Essex Rival, Advancer, Princess Royal. *Main Crop:* Champion of England, Paradise Marrow, Veitch's Perfection, M'Lean's Wonderful. *Late:* Ne Plus Ultra, Knight's Dwarf Green, British Queen. *Best four varieties:* Early Emperor, Princess Royal, Veitch's Perfection, British Queen. *Six good kinds, all dwarf growers:* Sutton's Ringleader, 2½ feet; Bishop's Long-nodded, 2 feet; Princess Royal, 2½ feet; Ringwood Marrow, 3 feet; Yorkshire Hero, 2½ feet; Knight's Dwarf Green Marrow, 3 feet.

POTATOES.—Veitch's Ashleaf, Flour-ball, Scotch Queen, Pink-eyed Regent, Queen of Flukes, Pink-eyed Fluke. These six sorts cannot be surpassed for productiveness, quality, and keeping. The following six are also first-rate: Golden Globe, Early Shaw, Prince of Wales Kidney, York Regent, Fluke, Milky White.

TURNIP.—Sutton's Early Short-top, Mousetail White Globe, Red-top Mousetail, Orange Jelly.

SMALL BEGINNINGS.—A most forcible illustration of the old adage that "Small beginnings have great endings," is afforded by the history of the Royal Insurance Company, to which our attention is especially attracted at the present time by the really wonderful progress recorded in the almanacs they have just issued for the current year. As the accumulated funds in hand amount already to as much as £1,200,000, we are induced to wonder what it will be twenty years hence, and to speculate on the probable amount of the annual revenue, now over £700,000, in the like period.

Replies to Queries.

Chrysanthemums for Pots.—C. F. H.—The following sixes will suit you: *Large:* Christine, Golden Christine, Mount Etna, General Bainbrigg, Annie Salter, Alma. *Pompones:* Helene, Bob, Andromeda, Cedo Nulli, Golden Cedo Nulli, Lilac Cedo Nulli.—R. W. Simson.—In case the selection made for C. F. H. does not suit you, we make another. *Large:* Little Harry, Pelagie, Golden Hermine, Prince of Wales, Lady Harding, Beauté du Nord. *Pompones:* Salamon, Mademo Fould, General Canrobert, Aurora Borealis, Duruflet, White Trevenna.—Chrysanth.—You describe your plants of Empress of India producing a few flowers the size of pompones, of a dark red colour. The probability is that in place of Empress of India you have Mr. Murray, or Bob, or some other variety in that way. Those you describe as like large daisies are no doubt what we call anemone-flowered kinds; some of them are extremely beautiful. The subject of pot culture shall have attention immediately.

Scarlet Geraniums.—Novice has a number of scarlet geraniums that were taken up in October, the leaves all removed, and the plants tied in bunches and hung in a nearly dark cellar, with a slight current of air through it. He wants to know if it would be advisable to wet the roots, in case they should become very dry, and when they should be again "put into the earth." This suspension of geraniums is a pretty safe way to keep them, for if properly conducted they do not die, but they are really not worth much after it. To wet the roots as they now hang is not advisable, because of the probability that they might become infested with mildew. We advise Novice to leave them as they are till the end of February, then to prune them root and branch rather close, and put them in small pots, in soil consisting of three parts sand and one part loam, and place them in a sunny window, giving them very little water for at least a month, after which they may have water twice a week. If taken care of, they will be full of nice leafy shoots by the middle of May, and may then be planted out again.

Stove Moist Heat.—J. H. D. inquires, What is the best means of obtaining a constant moist atmosphere in a house heated by one of Green and Brown's ventilating stoves? House 16 feet by 10 feet.

[Without seeing the stove, we cannot advise in a definite manner. There is nothing like a tank or a series of pipes for a constant heat. Perhaps a tan bed in the centre might answer—it would be in the hands of a gardener of the old school.]

Muscat Grapes.—J. H. D.—What grape having a good Muscat flavour would you recommend for a cool vinery? One writer states that "Bowood Muscat" will do moderately well, but would not one of the Frontignans do better?

[Champion Muscat is the very grape for you; but if too dear, take Chasselas Musqué, or Muscat St. Laurent.]

Changing Grapes.—J. H. D.—I wish to change some of my grapes (strong canes planted last March, and wood now ripe up to the top of the house). Shall I root out these, and plant the sorts I want, or shall I cut down those I have to one or two eyes, and graft or inarch them? or would you advise me to plant in the spring the new sorts by the side of the old ones, and take a full crop of fruit from the old vines, and then destroy them?

[It all depends upon the distances at which they are planted. If far enough apart, let them fruit, and in the meantime get up their successors. Inarching would be admirable if skilfully done. We should prefer your last proposal.]

Unripe Apple Wood.—J. H. D.—The young wood of my bush apple and pear trees (planted last January) is soft, and the bark spotted white and yellow, as if half-rotten: how shall I prune them? They have been pinched in during the summer.

[You must cut out all the soft and half-rotten wood to sound hard buds. Better lose all the last season's growth than keep worthless wood. But you will not have to go so far as that.]

Poinsettia pulcherrima.—Ensign.—This beautiful shrub is easily grown if it can have stove heat, but in a cool house comes to no good. The soil should consist of just such a mixture as fuchsias delight in—say turfy loam, peat, leaf-mould, dung rotted to powder, and sharp sand, equal parts. If the cuttings are struck too early, the plants are apt to grow leggy, but if too late, they may not bloom as early as required, and they are usually required at Christmas. It is a good plan to keep a few old plants to cut from at Christmas, as the green leaves and scarlet bracts are of great value in dressing vases, &c., &c. To make nice young plants, take cuttings in March, and dip them into pans filled with sand, and place on a heat of 70°. Keep them rather dryer than cuttings are usually kept when in heat, but do not let them flag. When rooted, pot them in small pots, and put on the tank or tan bed again. Shift as required. Strike a few more in May, July, and August. Summer temperature 65° to 90°; winter temperature 40° to 50°, and the plants then to be rather dry.

Books.—Old Subscriber can have no better book on the monthly work in the garden than a late edition of Aberrombie's, "Every Man his own Gardener." There are several newish books intended to supersede this old-established work, but they only serve, on comparison, to establish its superiority.—W. Wilson.—To reprint the "Rose Book" in those pages would certainly be a novel proceeding. We agree with you there, but we do not intend to carry the suggestion into effect. It is all stuff to talk about the "Rose Book" being dear at 5s. It is a handsome book, and the author gets something out of it. There are people, no doubt, who prefer books that are low-priced and bad, but we are not bound to gratify every foolish whim in such matters. We decline to supply hooks, so pray do not send postage stamps. We have before us hundreds of letters that want attention, and it is annoying to have to wade through such a mass of stuff as you send, to find that it all ends in your wishing us to give books away.

Ground Vinery.—In consequence of the number of applications for information on this subject, it shall have attention immediately.

Musell's Hot-water Apparatus.—P. T.—We have never used or even seen this apparatus, and can give no opinion of our own as to its merits. We have heard much in its favour, and never heard a word against it; therefore we do not think you would err in adopting it as you propose.

Justicias.—J. Honry.—1, *Justicia coccinea*; 2, shrivelled beyond identification; and 3, *Justicia speciosa*. Nos. 1 and 3 are first-class stove plants which flower in winter, and demand nothing beyond the most common care. They ought to be struck every year, and the old plants should be destroyed. Early in February is the best time to strike the cuttings. Grow them on liberally, and the next winter they will be fine plants, and will flower freely.

The Gardener's Magazine.

SATURDAY, JANUARY 12, 1867.

THE NATIONAL HORTICULTURAL EXHIBITION to be held in the gardens of the Botanical and Horticultural Society, Old Trafford, Manchester, 7th to 15th June next, meets with so much favour in the north, that if the promoters labour with their customary spirit and unity, their efforts must be crowned with success. The schedule contains separate sections for amateurs and nurserymen, in which the classes consist of plants only; there is a third section for fruit, which is open to all. The general plan of the competitions differs somewhat from the established routine in such matters, and it may be of some service to our readers if we point out a few of the most important features. The prizes are liberal—*eminently liberal*. Class 1, for 14 stove and greenhouse plants (amateurs), includes 1st, £20; 2nd, £15; 3rd, £12. The corresponding class for nurserymen admits only 12 stove and greenhouse plants, and the prizes are £16, £12, and £8. The lowest prize offered is 10s., and so small a sum as that appears in but few instances. Comparing the sections for amateurs and nurserymen, we have in the first a class for 20 exotic orchids, in the second a class for 12 exotic orchids. In the first a class for 10 fine-foliage plants; in the second a class for 12 fine-foliage plants. The amateur class for pelargoniums requires only 6 plants, that for the nurserymen requires 10. It is satisfactory to observe that zonale pelargoniums have been provided for; there are both amateurs' and nurserymen's classes for 10 zonale, 10 variegated, and an additional class for amateurs for 10 nosegay varieties. Ericas, stove and greenhouse ferns, rhododendrons, azaleas, amaryllis, palms, fuchsias, calceolarias, and miscellaneous subjects are severally entered, and prizes are offered for them in amounts proportionate to the sums already quoted from the schedule. The section devoted to fruit comprises a class for 10 orchard-house trees in fruit; 2 grape vines in pots; after which we have pines, grapes, melons, peaches, and nectarines. The total amount offered in prizes is £984 10s., which we may for general purposes describe as £1,000.

The exhibitions at Manchester have always possessed a character of their own. There are not only many good gardens in the suburbs of the cotton city, but the gardeners of the district have rarely been disturbed by those feuds in which the gardeners of the south delight, perhaps (and very likely indeed) because there never has been established between Manchester and the Royal Horticultural Society any very close bonds of relationship. Now it is a very strange thing that though the dates selected for the Manchester exhibition were announced long before the Horticultural Society determined on patronizing Bury St. Edmunds, yet for the Bury show the same dates were chosen, so as apparently to render the Bury show as much as possible injurious to that of Manchester. No one accustomed to watch the proceedings of the Society, and fully acquainted with its impotence for either good or harm, can suppose it capable of robbing the Manchester people of any the smallest part of the success that awaits them, provided they carry out their plan in its integrity, and are favoured with good weather during the days of the exhibition. Indeed we have but one object in alluding to the coincidence of dates, a coincidence we cannot refer to as "undesigned," and that is to put exhibitors on their guard in time, so that those who intend to exhibit at Manchester may take care not to enter for Bury, unless fully able to do justice to themselves at both places.

It is impossible to hazard any conjecture as to how far the great Parisian exhibition will interfere with the success of our own flower shows. People possessing wealth and leisure, and a majority of the patrons and practitioners of art and science, will of necessity spend a considerable portion of the forthcoming summer in Paris, and their absence may be felt at the principal metropolitan exhibitions. Yet there is always a great public to which the exhibitor may appeal with the certainty that merit will be appreciated; and there does not appear to be any special reason why the promoters of English exhibitions should be seriously influenced in the disposition of their plans for the approaching season. The horticultural part of the Paris exhibition is still in a lamentable state of chaos; and indeed the whole affair is so vast, that it cannot be rash or unneighbourly to fear that complete and unequivocal success is impossible.

No. 89, NEW SERIES.—VOL. X.

THE KINGSTOWN ROSE SHOW, which is to take place in connection with the Summer Exhibition of the Royal Horticultural Society of Ireland, has met with a very favourable consideration amongst English exhibitors, and we believe we may promise the promoters a spirited competition. The date of the show is fixed for June 27th, and the place of exhibition will be the New Grounds, Kingstown. The leading class is for 48, either single blooms or trusses on single stems. The highest prize is to be a cup value £10, the second a cup or other piece of plate value £7, the third value £5, the fourth value £4, the fifth value £3, the sixth value £2. Independent of the special fund for this rose show, and the special schedule by which it will be regulated, there are some rose classes in the schedule of the society affording abundant room for competition for stands of 36, 24, 16, and 12. We most heartily wish our Hibernian friends success, and again hint to our brethren in Caledonia that the human race are expecting something similar of them. A Scottish rose show would be about as useful as any show the Scotch florists could give their minds to at present.

THE WEEKLY NOTE ON THE PROBABLE WEATHER, which has till now occupied a prominent place at the head of each sheet, was commenced January 6th, 1862; hence the publication of the usual note on Saturday last completed the writer's fifth year of devotion to this task. When first the weather forecasts were commenced, the magazine was unknown; and probably this feature did quite as much as anything else to direct public attention to the magazine, and so prepared the way for the success that has attended the enterprise, and which it must now be confessed has proved fatal to the system of publishing weather forecasts, for the object of this note is to announce that they are to be discontinued. The writer of this can speak plain when needful, and he has a few things to say respecting these forecasts. In the first place, it has been demonstrated in black and white that it is possible to forecast the weather a week in advance, and to do so every week the whole year round, with only a small per centage of error, though the prognostications hazarded may be of a most distinct character, as in the case before us they have been. The five years' forecasts may be compared with any authentic record of the actual weather during those five years, and they will be found to have afforded decisive and generally accurate predictions of the meteorological events that occurred during the several weeks for which they were written. Since the middle of October, 1866, there has been a decided falling off in the value of the forecasts, and possibly, if they were continued, they would become utterly worthless; therefore, none of our readers need complain of their discontinuance. The continually increasing circulation of the magazine necessitates earlier printing than formerly. The last moment at which it is now possible to insert a weather note is noon on Thursday, whereas, three years ago, they were sometimes inserted at a late hour on Friday night. When the day for closing the pages was shifted from Friday to Thursday, it was thought that the task of writing the forecasts would not be seriously affected, but it was soon found that the anxiety connected with this department was increased immensely, and in time this anxiety became painful, and less attention was given to the subject, and of necessity the value of the weather notes was depreciated. It may not occur to all our readers to suppose that the framing of the forecast is a matter involving any great labour; but the truth is, if closely and conscientiously followed, the writing of the three or four lines every week is as much mental labour as any one person can safely engage to perform. Let those who doubt this hold assertion, qualify themselves for the task, and follow it till experience justifies them in accepting or denying the statement. There are some other circumstances, such as increase of labours of other kinds, and a somewhat precarious state of health for six months past, that tend to strengthen the determination to abandon this feature; but sufficient has been said to render unnecessary any minor arguments. The authorship has been concealed partly from whim, partly as a reason for avoiding useless controversies; but it may as well now be confessed that from the first to the last the forecasts have been written wholly and solely by SHIRLEY HIBBERD.

WINDOW GARDENING AMONGST THE WORKING CLASSES IN HULL.—At the general committee meeting of the Society for Promoting Window Gardening amongst the Working Classes in Hull, the sub-committee reported that the operations of the society have been of the most satisfactory character. Upwards of 700 orders were issued to applicants for plants, and 3,700 plants were distributed. A small balance still remains in the hands of the treasurer after payment for flower pots, printing, and other incidental expenses. This will form the nucleus of a prize fund to be distributed at a flower show which it is proposed to hold in the ensuing summer. Towards this fund many ladies and gentlemen interested in the movement have promised donations, and Messrs. Jameson and Co., Canning Street, have not only promised to assist the general fund, but to give special prizes to their own employes. Votes of thanks were given to Mr. Walliker, the honorary secretary and originator of the movement; Mr. Boulter, the treasurer; and Messrs. Niven, Botanic Gardens, and Peak, gardener, the Park, through whose united exertions the working of the society has been so satisfactorily performed. We understand that the Lord Mayor of York takes a warm interest in the movement, and we doubt not that not only that city but many towns will follow the example set them by Hull. The number of plants, nearly 4000, bears favourable comparison with the number distributed in London during the first year of the movement, which, according to Lord John Manners's statement, reached 17,000. Considering the vast population of London, this shows that the movement has already been well appreciated in Hull. Perhaps the most gratifying feature of the distribution of the plants was that all expressed themselves highly pleased with the selections made for them. Printed instructions were issued to every recipient, so as to acquaint them thoroughly with the mode of culture of the plants entrusted to their care.

HEATING HORTICULTURAL BUILDINGS.

Seldom if ever in the memory of an ordinary lifetime was the importance of a perfect and thorough system of heating horticultural buildings more impressively demonstrated than at the time of writing this, January the 3rd; for at 6 p.m. the thermometer indicates 23° of frost, and the appearance of the elements fully justifies in saying that before midnight it will most probably reach Zero. Such is the state of the external atmosphere, and I ask those who may read these lines, and who may happen to know anything about the imperfections of our system of heating, if such a state of the weather is not enough to set any sober man to thinking about the possibility of our attaining to perfection at last. However, it has set me thinking, and hence the reason of my taking up the subject just at this time, besides which it will be more likely to meet with attention than if deferred till winter has past and gone. To be properly understood, I must first say that I do not find fault with the principles of heating our plant and fruit houses; it is the manner in which those principles are carried into effect that gives me reason to complain. Many persons build houses, and set boilers, and furnish them with just one certain amount of hot-water pipes, without any consideration as to whether a proper amount of heating surface has been given to secure the success of the undertaking. I have seen many useful and handsome buildings erected, and a powerful and expensive boiler attached, and those most interested in it showing the utmost anxiety that these two essentials should be perfect. But when coming to the question of hot-water pipes it has been dealt with in a niggardly manner. There is a very simple means of ascertaining by calculation the amount of piping required to heat a given space of air, and this is often done to know the required quantity for any one house, and on the strength of such calculations inexperienced people act, and then comfort their minds in thinking that they have done all that means and skill could do—in fact, all that is wanted to be done to make their investments a perfect success. But such calculations are faulty; they cannot be said to be erroneous. They are faulty because they make the basis of their calculations an imaginary condition of the elements, not reckoning for external influences. Therefore it is that they are not applicable to the ordinary structures used as horticultural buildings, unless they make their calculations, which is seldom or ever done, from two extreme points. For instance, if we take a certain house in which the temperature ranges regularly at 40°, we can easily ascertain by calculation how much piping it would require to raise the temperature to 60°, and secure at the same time that there be sufficient surface, that the heat generated from the pipes shall not be of that parching character which results from pipes excessively heated, as they must be where there is insufficient surface. But then such calculations do not go far enough; they only proceed, we may safely say, to one extreme point, for a house that is maintained at 40° without artificial heat, must be favoured by an external atmosphere never lower than 35°. Therefore when we wish to raise this house by the application of artificial heat to 60°, we cannot expect that the same amount of heating surface that serves when the thermometer reads 35°, will serve equally well when it is 20° lower. Nevertheless many houses are heated in a way which compels us to suppose that the authors of the heating apparatus believed this to be possible, for there is no extra amount of piping sufficient to make up the required degree of heating surface when the external influences should demand it.

Now what is the consequence of this oversight, or rather I ought to say this deficiency of heating surface, which in every case ought to be secured in the first instance, so as to be available for use in an emergency like the present? Why, the plain fact of the matter is, we are obliged to heat to such a pitch the few pipes that we have, that the heat given off from them is so great that it is positively injurious to vegetable life, and our plants suffer to an extent that will be too plainly shown by future failures!

At the present moment, only a few yards from where I write, I can lay my hand on a return pipe in which the water must travel more than two hundred feet before it comes to the point in question, and yet I cannot bear my hand upon it more than two seconds. Yet, notwithstanding the heat I maintain in the pipes, the frost is gradually gaining upon me, but I cannot do more; for the last two hours all the force that the heating medium will allow me to apply has been given. But had I an extra supply of piping set aside for an emergency like this, I could not only wink at the frost, but the heat which I should secure from this extra extent of radiating surface would secure me a more suitable temperature in the house, as it would be less parching in its character, and the chances of a breakdown at this critical time would be considerably diminished, as there would be less force used to secure the same amount of heat. But mine is not the only case of the kind by very many.

Then in connection with piping, I would call the reader's attention to the prodigious size of some boilers as compared to the extent of pipes they have to heat. There is evidently much room for an improvement in this branch of heating, for I have seen some

instances where the boiler has been quite large enough to do double the work it had to do, and where such is the case there is a great waste of fuel. Before we can expect an improvement under this head, proprietors must pay less heed to the extraordinary recommendations of the manufacturers of the different forms of boilers. They will do better to call in some skilful practitioner who has had some actual experience in such matters. Then they may hope to get suitable advice, but to believe what we read in the glowing descriptions given of some boilers would be positively absurd. For instance, with a certain form of boiler night stoking is abolished; how ridiculous! when every gardener in the three kingdoms knows to the contrary, and the inventors themselves must know it to be impossible!

Closely allied to boilers is the use of dampers, but the question is, are they invariably used so much as they ought to be? I fear not, because it is seldom, if ever, that instructions are given to those who have the working of them as to the object for which they are intended. I served fourteen years as an under-gardener, and in one instance had the charge of three boilers for over two years, and the only instruction that I ever had given me was to use the damper when I wanted to keep the fire in, more especially of a night; but the idea that I might use the damper to a certain extent when I had a great roaring fire going, to confine the heat round the boiler, by reducing its means of escape, was foreign to my young notions. So I used to let it go to waste up the chimney, for the want of knowing better, and to the discredit of those who ought to have told me how to act. It was not until I became responsible myself for the amount of firing consumed that I began to turn my attention to the use of dampers, and to understand the purposes for which they are intended; so that I may be said to have found it out for myself. And I have also found that dampers generally are placed too far away from the boiler; they should be as near as possible, that when they are used to confine the heat, they may send back over the fire the fumes and smoke, that the inflammable portion of the gaseous products may be burnt, to the manifest saving of fuel; as if there is not the means of escape for all the smoke, there is sure to be a certain amount of heat that would go up the chimney retained and conserved, to the saving of the fuel.* But speaking of chimneys reminds me of an experiment I have tried this winter. I have reduced a 9-inch chimney (inside measure) to one half its original size close to the boiler, so that where the heat had previously a superficial square of 9 inches to escape up the chimney, it has now only half that space; the consequence is, I confine a greater body of heat round the boiler, thereby saving about 15 per cent. of fuel, and secure at the same time all the draught I require for the fire for a 4-foot cannon boiler.

As to the systems of heating applicable to horticultural purposes, hot water is unquestionably the best, but like all other things it can never be perfect. That it effects a great saving in fuel and labour none can deny, and I am in no way reluctant to give my humble opinion in its favour. But while doing this, I cannot ignore those means which were used to good effect by our forefathers, as many have done; for I have myself worked the old brick flue to a good advantage, and in the present day a strong well-built flue is not to be despised for small individual houses.

It has often been a matter of surprise to me that the Polmaise system of heating did not gain more hold on public attention for small houses, as it gives off a clean regular heat in which a great variety of plants appear to delight. I used it once for two years in a small conservatory, and certainly had no reason to find fault with its efficiency; the only part of it that I saw open to an improvement was the sharp angles of the furnace, which would sometimes prevent the coke sinking down to the fire properly. But as it is now almost entirely out of date, it will be only occupying space uselessly by discussing its merits further, and I will close this paper with just a word on the use of gas for heating purposes. This is only used yet in very small houses, and for them it is a very clean system of heating; but before the close of the present century, whoever lives to see it, will find that the use of gas for heating reasonable sized horticultural houses will become very general. J. C. CLARKE.

HORTICULTURE IN PARIS.—The cultivation of flowers and rare plants in Paris has for some years past greatly extended. This is due in a large measure to the municipality of the city of Paris, the gardens and parks of which are models of good management, elegance, and variety in the choice of their ornaments. At the beginning of 1855 the number of gardeners and workmen belonging to the municipality was only 3; in 1858, 12; in 1862, 40; in 1864, 60; and in 1865, 101. The plants and shrubs have similarly increased. In 1855 only 600 could be furnished; in 1863 there were delivered 1,602,265, of which 1,578,500 were furnished by the florist of La Muette, 23,570 by the nursery of Longchamps, and 3,186 by the fir nursery. A comparison of the accounts, from 1855 to 1865 inclusively, shows that the cost of the shrubs and plants got from the city nurseries and distributed during that period was on an average only 13 centimes.

* It is generally agreed among engineers and chemists that if smoke is once really formed, it cannot be burned. The philosophy of the smoke question, therefore, lies in prevention. The sole purport of a damper is to reduce the draught, and so check the rate of combustion.—ED. G. M.

ORNAMENTAL GRASSES FOR INDOOR DECORATION.

The art of embellishing our homes in winter with really elegant and pretty dried flowers is as yet but very imperfectly known. It is often attempted, but rarely or never successful, and chiefly from a want of knowledge of the best materials in this way. One would think that our great seedsmen who take up the matter ought to do it well, but they do not. Just look at a stand of what are called ornamental grasses, set up at a large flower or cattle show, and say if there be anything like grace or ornament about them. They are tied in rigid bundles, or perhaps projected into a sort of trifid little sheaf, an idea evidently suggested by an Isle of Man halfpenny, and they are in the greater part composed of grasses that have not any native beauty whatever, and which no amount of taste in the arranger could make graceful or attractive—common coarse grasses, in fact. It should be borne in mind that the fact of a plant's belonging to the grass family does not make it worthy of cultivation, and that we must select here, as much as in any other department of the vegetable kingdom, if we want to possess and enjoy the really beautiful. We know of nothing among plants more graceful or elegant than some of the grasses, and nothing so suitable for winter decoration, when cut at the right time and preserved properly—both matters of the easiest accomplishment. These flowers are essentially ladies' flowers, and may be cultivated and preserved by any lady with the greatest ease. The finest kinds may be grown in the open garden, either in a little bed to themselves, or scattered here and there in the borders. The best way is to have them in a bed to themselves, as then their state can be seen at a glance, and they are more likely to be cut at the right time than those in the borders and mixed about; but then they are so cheaply and freely raised from seed that there is no reason why we should not use them freely in both ways. Some of them look exceedingly graceful among flowering plants, while for indoor use we venture to say that when our readers try them they will never again purchase the abominations of dyed grasses now selling with very inferior everlasting as Christmas ornaments. As regards their preservation, the only point requiring attention is to cut them at the right time—i. e., before they begin to fade and drop their seeds; in fact, when they are in the full flush of grace and beauty in summer or autumn, as the case may be. After cutting, place them on a shelf in a dry darkish room, free from dust, and in a few days they will be dried and fit for use. In some cases, or in all cases, it is well to make a double harvesting of these elegant plants, so to speak. By doing so we get a useful variety in the panicles. When cut young, the spikelets and branchlets depend from the main stem at quite a different angle from what they present when the plant becomes a few weeks older. As for the culture, it is as simple as possible. Sow in pots in a cold frame or pit about the end of March, covering the seeds with a very slight quantity of fine sandy earth, not more than one-eighth of an inch for the largest kinds, except the seeds of maize or sorghum, if you should include these among ornamental grasses. Two or three six-inch pots of each should be sown, as if all the seed be put into one pot, the tiny seedlings will come up too thick. There is generally as much in a packet of seed as would sow four or five pots. In April these seedling grasses should be an inch or so above ground, when they should be gradually inured to the open air—i. e., left in a frame or pit that is only covered with its lights at night, or even only during frosty nights, and after a week or ten days in such exposed altogether night and day. Then they are soon ready for putting in summer quarters, which is also a simple operation. Those that are put in the borders or flower garden need simply to be taken out of their pots, the ball divided into half a dozen or more pieces, and these arranged in a circular group or patch. In the bed in which they are to be grown specially for cutting they are best placed out in lines, first preparing the ground well, and selecting a spot on some nice border in the kitchen garden, or reserve or nursery ground. Each little ball may be broken into a good many pieces, a better plan than pulling all the tiny seedlings asunder. They might hear that, but are a little too fragile for it. Place each little clump firmly in the ground, give a good watering, and all is over that need be done, unless the soil or season be unusually dry, when a watering would of course benefit. So much for character and culture. Next, as to the selection of sorts—the chief point. There are about 4,000 species of grasses known to botany, the greater part of which are no more ornamental than are wayside grasses, and consequently nothing is more frequent than for grasses possessing no claims to beauty to be sent out by seedsmen as "ornamental." From this vast host we shall select but a very few indeed, and take care that these possess not only distinction, but grace and beauty.

The most popular of all grasses generally cultivated in gardens are the Brizas. They are distinct and pretty, and though not equal to others to be presently named, worth growing. Being well known, we need make no further comment on them, the object of this paper being to draw attention to choice things not sufficiently grown. The largest kind of briza has a peculiarly neatly chiselled spikelet, suspended on a wiry little side-stalk. This type of grass flower will be found far more beautifully developed in a grass called *Bromus brizopyroides*, an extremely elegant species, having its spikelets like a briza, but more pointed at the end, and nearly an inch long. The rather long but slender stem which bears these droops or arches over in the most graceful manner, and the inflorescence when cut and dried is most valuable for vase decoration, either among freshly cut flowers, everlastings, or arranged with other ornamental grasses in a vase. It is perhaps the most gracefully drooping grass, as regards the disposition of the inflorescence, that we have in the country. It is offered in Mr. W. Thompson's catalogue at 2d. per packet, and as a packet is sufficient for any garden, that surely is cheap enough. But in gardening, as in many other things, we often give a great deal to produce results which might be equalled at trifling cost, and go a long way to find less than what Alphonse Karr found very near home.

Quite distinct from the preceding, but equally indispensable, and of quite what Mr. Ruskin would call a spiritual order of beauty, is *Agrostis nebulosa*, also a cheaply obtained and easily raised grass. It is called *nebulosa* from the singular aspect which it presents when in flower. A mass or patch of it, at a distance of a few yards, looks like a little cloud upon the ground, from the multitude of very small seeds being supported upon stems as fine as thread, and thus the densely spreading seeds, with their almost invisible supports, look like a fairy cloud upon the ground. When cut, and placed a little above the eye, the single stems of this grass have also a beautiful effect. It is the most suitable of all for mingling among *Rhodanthe* flowers in winter, or for any delicate small vases. Also marked at 2d. per packet in Mr. W. Thompson's catalogue (Tavern

Street, Ipswich). We select this catalogue particularly, because Mr. Thompson is a botanist as well as a seedsmen, and everything is truly described in his list, and, what is more, truly named.

The smallest of all the pretty grasses is *Airopsis pulchella*, which can scarcely be called elegant, as its inflorescence does not rise more than a few inches from the ground, but there forms dense bushes of seeds. It forms an interesting object on low rockwork, or on the front margin of a border.

Next comes what is probably, on the whole, the most useful of grasses—*Panicum capillare*, usually sold by the seedsmen under the false name of *Eragrostis elegans*, and therefore it is perhaps best to order it by that name. It is a very strong and free-going species, forming dark green hairy bushes about two feet high, but with the inflorescence shooting out in the most elegant manner. When emerging from the sheath, the numerous slender branchlets have the effect of the numerous tiny streams of water that flow from a finely perforated small syringe. It should be cut in this stage, and also when further developed, as the panicle presents several distinct aspects during the course of their development, and when cut and dried these different states preserve their peculiarities. It is a most useful, distinct, and elegant grass, easy to grow, and should find a place in the mixed border or flower garden, as well as in the bed devoted to growing ornamental grasses for preservation.

The common millet, *Panicum miliaceum*, is a very graceful, medium-sized grass, with a pretty drooping fingered panicle.

The German millet, *Setaria germanica*, has a bold, densely packed cylindrical spike of seeds, quite unlike any of those previously named, and worthy of cultivation on account of its distinction. The great heads of seed droop over from their weight, and look very effective among the stronger kinds in vases.

Hordeum jubatum is sometimes called the squirrel-tailed grass; and very beautiful it is, being simply a dwarf kind of barley, with the awns very close set and very silky. It is difficult to dry and keep, but looks peculiarly beautiful in the border. The seeds are apt to fall off in the drying, and of course then the beauty is lost; but it should be in every collection of ornamental grass, if only for its beauty when growing.

The singularly pretty hare's-tail grass (*Lagurus ovatus*), which grows naturally in sandy places in Guernsey, is one of the very best, and from its novel outline and silky softness, indispensable among dried grasses, and, indeed, useful for putting among cut flowers at any time.

There are two other British grasses quite as well worthy of culture as any exotic ones—*Milium effusum* and *Agrostis spica-venti*. The first is a handsome grass, rather common in British woods; and the second is only found in some of the eastern counties. *Agrostis spica-venti* is a very graceful thing, growing about eighteen inches high, with plummy panicles of a silky hue and texture; very rarely seen in gardens, but would form a charming addition to ornamental grasses. We are convinced that many of our readers would find this and others of the grasses enumerated in this paper more graceful than any fern; and when it is considered that their beauty may be perfectly preserved for twelve months after cutting, they will agree that no plants offer such attractions to ladies fond of arranging flowers.

There is another exotic milium, *M. multiflorum*, which should be obtained, as it has long slender drooping stems, from which are suspended little round seeds by slender thread-like branches—a most graceful grass. So much for the annual kinds of grasses, and now a word for the strong perennial kinds.

The smallest and not the least valuable of these is the common feather grass (*Stipa pennata*), a hardy border perennial, the long and streaming awns of which are sold so much in Covent Garden, both in their natural colour and in a dried state. It requires no special treatment whatever; merely wants a place in the mixed border, or if it be much required for drying, a little live of it might be put with the herbs in the kitchen garden. Cut it early, or the seeds will ripen, and then of course the beauty falls to pieces when the seeds fall.

In addition to this, it is only necessary to mention the magnificent pampas grass, which everybody is acquainted with. Its plumes should be cut when young and fresh, and not left till they get a dirty tone in the late autumn. Of course we mean those that are required for indoor decoration, and wherever there are good plants enough spikes may be thinned out without interfering with the beauty of the specimen. The small side branchlets of the pampas, pulled off and used among the smaller grasses, look very well, while of course the noble plume in its entirety is an ornament in itself.

Somewhat like the pampas in habit, but smaller and earlier, is a comparatively new hardy grass, *Arundo conspicua*; it blooms very nicely in the southern and midland counties.

Finally, we have a word to say for *Arundo donax*, the great reed of Southern Europe, which, though it does not flower in Britain, is most valuable from the great dignity of its cane-like habit. It grows ten or more feet high in the flower garden at Syon House, and will be sure to give satisfaction on good soil in warm districts.

The grasses recently shown by the seedsmen at Islington were, as usual, wretchedly arranged and very badly selected, and offered no guidance nor encouragement for the culture of this very graceful family.—*The Field*.

THE VIRTUES OF PENNYROYAL. BY A FARMER.—Much the largest number of fleas are brought into our family circles by pet dogs and cats, and the pigsty is generally filled with them at this season of the year, where numbers will hop on you when visiting it for the purpose of feeding or inspection. The oil of pennyroyal will drive these insects off; but a cheaper method, where the herb flourishes, is to throw your dogs and cats into a decoction of it once a week. Mow the herb and scatter it in the beds of the pigs once a month. I have seen this done for many years in succession. Where the herb cannot be got, the oil may be procured. In this case, saturate strings with it and tie them round the necks of dogs and cats; pour a little on the back and about the ears of hogs, which you can do while they are feeding without touching them. By repeating these applications every twelve or fifteen days, the fleas will flee from your quadrupeds, to their relief and improvement, and to your relief and comfort in the house. String saturated with the oil of pennyroyal and tied around the neck and tail of horses will drive off lice; the strings should be saturated once a day. Mint, freshly cut, and hung round a bedstead, or on the bed furniture, will prevent annoyance from bed insects.

FLOWERS IN ROME ON CHRISTMAS DAY.

The *tramontana*, which has been rather troublesome lately, forbore to blow on Christmas Day, and in the sun the weather was as warm as June in England. The *forestieri* all rushed out without their great-coats, and the ladies without their warm shawls, which may account for the numerous cases of relaxed sore throat of which I have since heard in polite society. I counted, however, on the Pincian, no fewer than thirty-four pairs of white pantaloons among the male Romans, which for the 25th December were pretty well. At every street corner and under every archway there were stalls heaped high and thick with fresh flowers—with heartsase, mignonette, monthly roses, violets, camellias, ferns and grasses, and wild flowers without number as to species, and without names so far as my powers of nomenclature extend. Next to the environs of Seville, where everything which is not covered with oranges is covered with roses, and the Valley of Mexico, which is one *parterre* of flowers all the year round, must come Rome as the chosen haunt of Flora. She revels in wild flowers among the ruins, the tombs, the chinks of the Colosseum, and even in the waste Campagna. She runs over with tame flowers in the gardens of her villas which fringe the Seven Hills. Flowers in Rome are literally cheaper than dirt; for dirt is a dear article—it costs lives. For penance you might buy such a bowpot in Rome as an English duchess might think cheap at a guinea in Covent Garden; such a bowpot as might make an English sempstress, stitching in her solitary garret, calculate how many hours of toil and miles of needle and thread it would take to purchase one poor sprig of mignonette from that abounding loveliness. You are spared in Rome the detestable nuisance of the flower girls who in Venice and Florence dog your footsteps and thrust bouquets into your button-hole whether you will or not. Every street corner or vacant place is, as I have said, a *Marché de la Madelaine*, and you can spend your loose halfpence in flowers, or leave them alone, as you choose. The only peripatetic vendor of flowers whom I have yet met in the Eternal City is a humpbacked dwarf, who on week days haunts the outside of Piale's reading-room on the Piazza di Spagna, and is a small Birnam Wood of choice flowers. You may make poor Lancelot Gobbo's fortune for a fortnight if you give him say forty bajocchi—'tis but 1s. 7d.—for an armful of rainbow. On Sundays, when Piale's, in deference to the prejudices of its Protestant patrons, is closed, the dwarf changes his station to the outside of the Caffè di Roma, on the Corso, whither, it may be hinted, a considerable section of the Protestant patrons resort to read the last *Galvani*, invisible at Piale's. On the Sabbath the Gobbo does not vend flowers. He has a pair of buffalo horns for sale, beautiful in their polish and curvilinear spikiness, with which he stands sentry, a horn in each hand, like a stunted terra cotta figure of Plenty, bearing ossified cornucopias. With a view to Protestant patrons, he has mastered a small stock of English. "Little lady, buy flower? bu'fil." "Little gentleman, buy horn? bu'fil." Beyond this his Anglo-Saxon does not extend. You might fancy him to be of the family of Albert Smith's donkey-box at Alexandria, with his "Giv'um sixpence; ole gentleman always giv' um sixpence." I have often purchased flowers from the dwarf, but I have not yet ventured upon a pair of buffalo horns. Such a possession might give a subject for a postscript to the author of "What will he do with it?" What should I do with a pair of buffalo horns? How should I pack them? How bestow them when I got my horns home? I have an idea that when I take to discounting bills at sixty per cent.—which is not at all an unpractical way of winding up a froward and turbulent youth—I will buy a pair of buffalo horns, and hang them up in a bleak counting-house in Tavies Inn, between a Ready Reckoner and a List of Terms in the Exchequer of Pleas. They shall be typical horns, and symbolical of hardness and smoothness, and of the ultimate impalement of my acceptors on the spikes.

I confess that the sight of the blue sky, the bright sun, and the fresh flowers rather threw me out in my reckoning, and rendered my ideas of parallels of latitude somewhat hazy. "How to have fresh roses on Christmas Day" is a recipe I cut many years ago from one of the early numbers of the pleasant old *Family Herald*. Remembering that old Time is still a-flying, you gather your rosebuds while you may, and whenever you have any spare pence in your pocket; and snipping off the end of the stalk carefully with a sharp pair of scissors, seal them carefully with red wax—black is unlucky—wrap them in silver paper, and put them in the top left-hand drawer in the best bedroom, punctually locking the drawer, lest Betty the housemaid's curiosity should be the means of your buds prematurely blowing and withering—as is the way with roses and housemaids. Then on Christmas morning, if you haven't lost the key and forgotten all about your hidden treasures, you unlock the drawer, release your buds from their prison of tissue paper, snip the stalks again above the sealing wax, pop them into lukewarm water, and lo, in the course of ten minutes, your roses are all a-blowing, and you may go down to breakfast with a flower in your button-hole, as proud as a dog with two tails. This is the pleasant theory. I remember that I once tried the recipe practically. It was a dreadful spectacle which broke upon my eyes on Christmas morning. So much stained tissue paper, so many dried and withered leaves, and a skeleton stalk or two. That was all. Did you every assist at the unrolling of a mummy? Did your horse ever shy at the skeleton of a cow picked clean by obscene birds in a mountain gorge by moonlight? I felt, gazing on the dead roses, as men have felt when they have come upon such sights as those.—*Special Correspondent of Daily Telegraph.*

THE FOOD OF PLANTS.

There is no branch of horticulture so little understood, or which seems to command the attention of the gardener less, than this; and yet much of the success of plant, fruit, and vegetable growing depends upon a knowledge of what to give for food and what to avoid. But if we take the ideas and theories of our great horticultural chemists, and reduce them to practice, we shall have made a great advance towards securing the proper necessities for our garden pets. One fact is known and common to all, that for plants to grow and produce their peculiar secretions they must be nourished by the absorption of food both from the air and earth; and although it is a fact that almost all plants will imbibe sufficient chemical properties from the atmosphere to sustain them, still this will only last for a definite period, except in the case of Epiphytes, and such plants as hyacinths, &c. The potato has the power of growing and reproducing its kind, and forming new branches, without any contact with earthy matters at all. According to the theory of Lindley, the chief food of plants consists of carbonic acid, nitrogen, and water, with various mineral matters, chiefly alkaline, but which differ in nature and in different species, and the roots of plants possess the power of selecting from the food which is

presented to them such matters as are most nutritive and best suited to their constitutions. This then will explain the practice of the rotation of crops. We find that many kinds of crops, especially the cereals, will cease to fructify if grown in the same soil year after year in succession. Roots obtain carbon in the form of carbonic acid, derived from the atmosphere, or from the decay of vegetable matter in the soil in contact with them. Plants can only take food in a liquid or gaseous form, and yet how often do gardeners offer food to plants in the form of solids. They have no power of taking these up; the spongioles are only empowered to take up ammonia, or other chemical constituents, when held, as above stated, in solution. Another important agent, hydrogen, is obtained by the decay or decomposition of water, and is assimilated with the carbon while the oxygen of the water, or of carbonic acid, is liberated. Nitrogen is secured for plants in the form of ammonia, and although a theory is of long standing that the atmosphere does not afford a supply of this important gas, a well-known authority, Rigg, asserts that plants positively do obtain free nitrogen from the atmosphere, and his assertion is founded upon a careful series of experiments. The chief use of nitrogen to plants is the production of the young parts, such as the bark, leaves, seeds, &c., and it is almost or wholly wanting in old parts; this fact will explain why young wood when it has passed the hands of the artificers decays so much sooner than old or heart wood; in the latter it is never found. Now, although the above are the principal agents which afford food to plants, still there are many others, though of minor importance. Minerals are necessary—in the absence of which many genera of plants will not survive; deprive the wheat plant of silica, for instance, and all the artificial power that can be brought to bear will prove unavailing in producing a crop. This will then prove how important it is to know something of the nature of the different plants we have to nourish, preserve, and mature, both for commercial purposes and for pleasure; we should likewise know when to apply and when to withhold stimulants, for it is just as easy to feed a man through the soles of his feet as to attempt to make a plant imbibe food when the growth of the plant or roots are at rest or inactive. Therefore it is when a plant is in activity, when the carbon is rapidly changed, and the water given off by respiration, that food should be applied. There is at this time such a demand made upon the spongioles of the plant, that they quickly exhaust the medium in which they are placed; and at such times when food is applied, the plant should be exposed to the full influence of light, or the requisite changes do not take place in the laboratories of the plant. Light alone has the power of changing part of the water into the green colouring matter termed "chlorophyll," which gives the beautiful green colour to leaves. In the absence of light, this process does not go on, hence the blanched and unhealthy state of the leaves. Seakale and other similar esculents, when prepared for table, are prevented forming chlorophyll, or in other words are blanched by keeping the plant in perpetual darkness, with excitement. The carbonic acid, ammonia, water, and other chemical agents, remain unchanged, for no assimilation of the food taken up by the roots takes place, oxygen of course accumulates, its natural proportions to the other elements is disarranged, and a decay or destruction of the tissues ultimately ensues.

This then will suffice to prove how important a matter it is to secure a due amount of light, also an unchecked healthy action in all plants, and that the food applied be composed of those agents which will at once be speedily taken up, and the plants thereby benefited. The great chemist Liebig has done much to instruct us in horticultural chemistry. His late work (a small neat pocket book), "Letters on Chemistry," will, if carefully perused, prove that gardeners can in many instances get more food for plants from natural and other sources, than by expensive artificial agents. In the neighbourhood of our great towns more ammonia is held in suspension in the atmosphere, and actually conveyed to our very plant-houses by atmospheric deposition of moisture, than is contained in many a shipload of Peruvian guano; and yet how sluggish we are to secure this invaluable food for our pets.

J. RANSLEY TANTON, F.R.H.S.,
Nurseryman.

Epsom, Surrey.

HAYS'S CONSTANT STOVE has had a fair trial during the recent severe frost, and has acquitted itself most admirably. We have no hesitation in pronouncing this the very best stove for small plant-houses of any that have been hitherto submitted to public notice. It happens that we have tried every kind of apparatus offered as a substitute for flues and pipes, having in view to advise, to the best of our ability and experience, the thousands of possessors of small collections of plants, who, for the most part, only want a cheap source of heat to tide them through a frost, and who of necessity prefer a small compact portable stove to any of the more elaborate methods of heating. To two inventions amongst many we award whatever praise is due for the merit of accomplishing all that is desired in this way, and these two are MUSGRAVE'S SLOW COMBUSTION STOVE, made by Messrs. Musgrave Brothers, Belfast, and HAYS'S PATENT CONSTANT STOVE, for which Mr. H. Baker, of 17, Harp Lane, Great Tower Street, London, is the sole agent. On the first of these we have reported on more than one occasion. Respecting the second, we have to say that it is extremely elegant in appearance, demands but little skill to manage it, and is as "constant" as its name requires it to be. The fuel used is peat charcoal, which happens to be very cheap. The stove can be used with or without a pipe to carry off the fumes of the charcoal, and when the pipe is not used, the fuel itself is made to absorb the products of combustion. There is no perceptible odour or closeness in a house or chamber in which one of these stoves is kept burning, even when there is no pipe attached. The amount of heat produced is never great, but it varies very little, as a rapid draught is next to impossible. Our observations have been made upon a double case stove measuring 4 feet in height by 1 foot wide. It is used to heat a small fernery, and at the present moment the house is scarcely less green than in summer, and there is not a particle of dust to be seen on any of the fronds. This stove will burn 14 hours without attention, and we believe it might be made to burn 24 hours without being once looked at. But 14 hours is enough for all ordinary purposes.

SAMUEL STAFFORD, HYDE, NEAR MANCHESTER. *Catalogue of Forest and Fruit Trees. Catalogue of Stove and Greenhouse Plants.*—These are in every respect first-class lists—comprehensive, accurate, admirably got up, and the several sections accompanied with valuable suggestions in respect of cultivation and display.

ARTIFICIAL HEAT.

By far the most important agent in the culture of indoor plants is heat. The supplies of light and water are more or less intermittent, but in the absence of heat plants cannot live.

The management of artificial heat has been more misunderstood than any other subject that the gardener has had to deal with. Scientific treatises on heating seem to have been aimed too high, and consequently to have missed their mark, for in my time horticulture had but very rude heating gear. A brick and tile flue, with a rusty door and bars, usually placed in a vault like the dungeon described by Sir W. Scott, "where damp and darkness seemed to strive," was our ordinary heating apparatus; and I must here remark that excellent grapes and pines were grown in houses thus heated, but extraordinary care and attention were needed, for as the flues were over-heated or otherwise, the heat would be sulphurous or ambrosial. I am not, however, going to rake up the embers of all the systems of heating that have come under my notice during the last thirty years, nor am I going to praise or to blame manufacturers.

Well may we admire the pious recluse who inscribed on his sun-dial—

"I only count the hours that are serene."

This text applied to horticulture would set us all on the right track, for unless such plants as the vine can get a certain number of halcyon days, they could not fruit. The great disturber of serenity is wind, but under glass we can easily and effectually exclude that; where, however, this is done it is not all gain, for without a breath of air blossoms are barren of fruit. It is, therefore, much easier to find fault with the wind than to find a substitute for it. A well-managed viney in this country will, for grape-growing, surpass any climate in the world. The artificial supply of heat we give is only to supplement the natural heat; indeed, the sun heat, when bottled up in a glass-house and brought under some sort of control, must be looked upon as decidedly artificial. The culture of alpine plants is positively impracticable on account of the difficulty of imitating their comforts in their native habitats. Under the snow they enjoy dryness and a perfect calm for months, and they are never in darkness, for I remember right well that when the snow-drift had made a clean sweep over my cottage in the far north, there was still a "dim (if not a religious) light" like that of frosted glass, to be seen through the windows. The cold and the dryness that the alpine plants experience is quite constant; we have no such comforts to offer them in our gardens, and the calmness and the light under the snow is perfectly inimitable by anything that we could do. The man who has plodded through life on level ground can form no idea of the serenity of a wintry day in a wood of full-grown Scotch fir trees, as it is seen and felt on some spur of the Grampians. The calmness and dryness during the times marked on barometers as "fair and frosty" are delightful. I have been assured by a gentleman who had spent some years in Siberia that the dryness of the air during the long frosts moderated the severity of the cold; and we have it from those who accompanied Captain Parry that they suffered most from wind and thaws.

The summer treatment of alpine plants is simple enough, generally speaking. Their growth is sudden and their growing season is soon over, and we all know to our cost too well that it is the winter season that tries the skill of the grower of alpine—damp, with its train, or rather its trail of evils, slugs, snails, mice *cum multis aliis*, destroyers all, preying upon the defenceless plant during what ought to be its period of rest: "the pause between the world destroyed and the world restored." Now mark here how beautifully all these evils are fenced off by three or four months of perfect safety under the snow; while they are ruined by one or other of the various forms in which artificial heat reaches them. I recollect once seeing a collection at the Rectory, Trentham, where shutters were so arranged as to keep the sun and rain off, and the plan succeeded admirably.

In using artificial heat to keep frost out of any glass-house, it is of the greatest service for the health and welfare of the plants to have sufficient heating-power to dry the house by day without raising the temperature too much. This of course must be done during the hours that the house can be ventilated. I dare not enter here upon the subject of wintering half-hardy plants, *alias* bedding plants. If plants could be said to suffer cruelly like animals, I should point out to the society for prevention of such cruelty, the London "cold frame," where our summer flowers are wintered under glass, with a foot of stable litter over the glass to keep the frost out. In mild winters the plan succeeds pretty well, but in severe frosts the loss is enormous. As it is, the wind that carries the frost through every cranny, and the damp that predisposes the plant to freeze, it is easy to see that since very dry peat will not take water, it is an excellent material to plunge plants in, where dryness is needed. Hence the success of peat turf-pits with glass overhead, as may be seen in the reserve gardens at some of our most noted show places for wintering such plants as *calceolarias*, and for early spring work.

From the time that the Lancashire gooseberry fancier placed pans of water under his choice bushes that the vapour rising might feed the foliage and so swell the fruit, the vapour theory and practice has been held in high repute; and I need scarcely remark that this "cunning device" has been imitated indoors in all manner of ways. Now I have often wondered what kind of a burning desert it would be in Nature that could yield such vapour as we see raised constantly from hot flues or cast-iron pipes—for the article that produces dry heat is not by any means thereby qualified to produce vapour in a healthy state of plants. The hot dry day with its full glare of light is unquestionably right, but the hot dry night with its darkness is as unquestionably wrong. If we take the vine for example, we have a plant that will bear more ill-usage than most plants, and yet live; but, on the other hand, we have in the vine a plant that tells better than most other plants can do, when it is well used. When a viney has been steaming like a brewer's vat, it will not injure the plants—it may even be of some service, a little better than so much dry heat; but surely this can be no reason why the foliage should not be supplied with colder vapour, just as it would be in nature after a hot bright day. It may be difficult to explain to a superficial observer the difference between a vine leaf after a hot and dry night in a house rightly called a forcing-house, and a vine leaf that has been grown under glass without any fire-heat. There will be a crispness about the leaf of the natural vine that is not to be found in the forced one, and in the early morning the hairs of the natural vine leaf will wear the sun dew like a crown of jewels, and feel stiff as if it had been clear-starched. Whilst, therefore, it may be necessary to sprinkle the walls and pathways fifty times a day to get healthy vapour, the hot pipes should not be sprinkled when

they would raise clouds of steam—when they are only warm, it is quite another matter. The time for a high temperature at night is certainly gone by. On the other hand I may state that exotic plants like the pine-apple will bear, not only with impunity, but with much benefit, a temperature higher than we have generally given them—even an amount of bottom-heat apparently perfectly unnatural has been found to forward their growth and swell their fruit; but such is the rigid character of the foliage of the pine-apple, that we look in vain to its prickly selvaige for nice tests of climate, and I have often thought that the pine-apple got more support from the water stored in its sockets than it did from the few roots and the hatful of soil that it had in the 12-inch pot. If space would permit, I might instance the support that hyacinth flowers get from a glass of water; and the gouty leaves of the American aloe would help my case, as they seem to bide their time till they are big enough to risk the flower and seed business principally on their own account, and certainly without much dependence upon their roots for support. I may have more to say on this subject at some future time.—A. FORSYTH, in "Gardener's Chronicle."

DEATH OF MR. WILLIAM KIDD, OF HAMMERSMITH.

Mr. William Kidd, so long and so well known as a writer and lecturer on song-birds and other domestic pets, died at his residence in Hammersmith on Monday last, in his sixty-fourth year. To record this event is an exceedingly painful task, for the public have lost a useful servant, and the writer of this note has lost a much-valued friend. It seems but proper to speak of the departed gentleman both as to his public capacity and his private character, for the whole of Mr. Kidd's public life was the reflex of the most sacred feelings of his mind and heart; he felt and believed what he preached, and possessed all the love for animals and all the skill in their management which he professed in his works. As a writer he never travelled beyond a certain limited range of subjects, but within that range he was a master. His "Book of British Song Birds" is not only invaluable for its natural history and sound advice on the proper management of caged birds, but enjoyable for its fine poetic tone, its racy anecdote, and the fresh, original, sparkling style in which it is written. If Izaak Walton's "Angler" is worth reading by people who do not catch fish, Kidd's "Song Birds" is worth reading by people who do not care to distinguish between the chirp of the sparrow and the song of the nightingale. The book is rich in its humanity, bright with sallies of wit, and graceful everywhere with its adornments of fancy, to justify this praise of our dear departed friend. Here is an extract, taken almost at random from his description of the skylark:—

"To enjoy thoroughly the notes of the skylark, and to estimate his capabilities as a bird of song, you must rise early. Early rising is essential to health. Nobody will deny that. So that we have two valid and cogent reasons for quitting the pillow betimes. Whilst we write (and it will be the case for some time to come), the birds hold their matins at 3 a.m., these continue till half-past 4. The choristers then cease to sing in concert, and each improvises a melody of his own, varying it as he pleases. We only ask you, good people, to rise *ones*, and listen to the voices of the birds at the hour we have named. *If you have a heart*, you will not require to be 'called' on the morrow, to enjoy a second benefit. You will, rather, lie awake, anticipating what is in store for you. To hear the birds warble their Maker's praises, would undoubtedly set our hearts in tune—were they not, alas! made of such impenetrable material.

"The skylark takes his stately steps among the wet grass at early dawn. Bedabbled with dew (his eyes sparkling like diamonds of the purest water), he rises gently on the wing, exercising his voice in sweet undertones before bursting into full song. Then does he warble forth a lay of love to his heart's idol, and address himself at once to Heaven's gate—there to do homage to his great Creator.

"See how he rises, high on the wing, determined for a season to lose sight of all below! Upwards he goes! And what sounds are those which descend and ravish our delighted ear—every note different, yet all breathing the purest melody!

"His heart is full of love. It overflows; and the benefit distils upon us:

Higher still, and higher,
From the earth thou springest
Like a cloud of fire;
The blue deep thou wingest,
And singing still dost soar, and soaring ever singest!

"Now he has entered upon brilliant cloud. He seems nearing the sacred precincts, the fond object of his flight. His voice is softer. The strains are those of a seraph. He is lost to sight!

"We listen—all is hushed—he is worshipping!

"It is now time for us to retire; and as we retrace our steps, let us each take a sweet morning lesson from this aspiring bird. 'Upward and onward!' be our motto."

It is unnecessary to speak of other products of his pen, except to say that he was a contributor to several periodical works, amongst them the "Gardener's Chronicle," the "National Magazine," and "Recreative Science," and that he published a journal of his own, bearing his own name, which was the delight of naturalists, and one of the most original periodicals ever produced.

In his private character he was all that a reader of his works would have expected. He was more. The fine humanity which pervades his writings was no mere abstraction; it exhibited itself in all his acts and conversations in the form of a deep and reverential love, having for its foundation the spirit of true religion. Joined with this he had a fund of humour and a capacity for *abandon* truly remarkable. There could be no dulness after William Kidd had joined a social party, and the more especially if there were young people present whom he could entertain with his comical descriptions of sparrows and pigeons, illustrated by performances that are quite indescribable, and by witticisms that were as original and sparkling as the best efforts of his pen. In the treatment of "feathered pets" he was a perfect magician. He could tame a screaming parrot by a few gentle passes of his hand, which in his comical way he called "mesmerising;" and he would take small birds out of their cages and kiss them, and they would appear to know him at once, and sing in his hand, though never having seen him before. These feats, and others equally remarkable, he has performed in the house of the writer, but he did not know they were feats—it was so perfectly natural for him to be on familiar terms with birds; indeed, he had a number of bird acquaintances that had never been in cages, and that used to come at his call as he walked about his garden, and take food from his hand.

But all this is as nothing to the goodness of heart that governed every action of his life. He had but few prejudices, and those were pardonable, for they wore the apparent results of some peculiar views he held in regard to the ultimate happiness of the human race. He was no sectarian, but a thorough hater of sectarianism; but he aimed at realizing what he conceived to be the highest form of practical Christianity, and from his faith derived guidance and courage and consolation. William Kidd is no more; the ripe fruit has fallen from the bough, and has been gathered home in peace and safety. Mr. Kidd has left a widow to weep at his grave. If ever a public writer was aided in his labours by good wifely counsel, wifely affection, and those home comforts which only a wife can secure, and which a man of his temperament could highly appreciate, then was our friend, and we through him, indebted in some part to Mrs. Kidd for the good accomplished in the course of his honourable career by William Kidd, Esq., of Hammersmith. S. H.

PRUNING THE VINE.

[The following paper is reproduced from the GARDENER'S MAGAZINE of Feb. 7, 14, and 21, 1863, in obedience to requests so numerous and so pressing that we have no alternative but to comply. It is hoped the roughness of the cuts will be excused; they are the same as were used in 1863.]

It has been our lot sometimes in the way of business, and sometimes for pleasure, to visit a great many large and small gardens in various parts of the country, and while even in the great places the vinerics are often a cause of extra anxiety, and sometimes are a failure, in the small single-handed or two-men places, we must candidly confess that if there was a weak place in the management, it was generally found in the VINERY.

No doubt in many cases there were valid reasons why this should be; sometimes a bad border made by a blundering predecessor, at others the limited amount of glass obliging the man to grow plants to the injury of the vines; but let the young gardener remember that this should never be done when it can by any possibility be avoided, for however pleased the employer may be with the fuchsias and gloxinias, yet the time will come when he will naturally go to the vinery for grapes, and no plants or flowers will compensate for their absence.

But there are some places where none of these excuses can be made—where the gardener made his own border—where there is no necessity to grow plants in the vinery—where the employer has not stood for expense, and after all has only been rewarded with "little miserable, discoloured bunches." This is no fancy sketch, but what all of us have seen somewhere or other—men calling themselves gardeners, yet failing, because they do not understand the management of the vine after all that has been written on the subject.

If then the professional, whose whole time and attention should be concentrated on his business, finds vine culture attended with many difficulties, how much more shall we excuse the amateur if he frequently finds himself in a fix, and appeals to the editor of his gardening periodical to help him out of it; and the great question now forcing itself upon us is, "How shall I prune my vine?"

This problem might be tolerably easy of solution if we could have a look and see how each patient has been treated during the past summer; but as that is impossible, we must try and make our instructions as plain and explicit as we can.

For instance, we last May made the acquaintance of a City gentleman who has a nice house and garden ten miles from London. Everything outdoors was well managed by a labourer, but the greenhouse was managed by the owner himself. He told us he "could not think how it was, the vine made a vigorous growth every year, and yet the fruit was always small, and not worth eating." We promised to look in once a week, and if possible find out the reason, and it was not long before it turned up. We walked down the garden one fine summer's morning, thinking, "Well, I suppose the grapes are as big as peas, and the vine will want stopping," and carelessly opened the greenhouse door, when, to our horror, we found the vine had been stopped at the first joint beyond the bunch, and every fruit-bearing shoot stripped of its leaves. Here was a reason with a vengeance. We expressed our dissent in no very measured terms, and were at once met with, "Well, I did not know any better." We promised to help him out of the scrape on condition that he did not touch them again, and the result was that laterals started from almost every eye, and were trained to again clothe the shoots with leaves; the berries soon began to grow, and ultimately there was a nice crop of Black Hamburgs, pronounced "quite a credit to an amateur."

Again: we know another greenhouse built last March, the aspect due east, and shaded on the south-east by a large villa, and on the south end by large trees and shrubs, yet considerable expense was incurred in making a vine border. Vines were planted, and although they were as green at the end of November as they were in July, the owner still thinks he shall get a few grapes next year. He is only a young beginner, and does not know that with such an aspect and with such wood it is next to an impossibility.

We will therefore suppose that the grapes are all cut, the leaves are all off, or come down at any time we like to shake the vine, that the young wood is the colour of cinnamon nearly to the end of the shoot, and whatever the previous training there is something to come out. Now we will take first the vines planted last spring; some have planted small canes not stouter than a good straw; if properly managed, these were started from a bud near the ground, and if in congenial soil, &c., will have made a shoot from 6 to 12 feet long; if only 6 feet, and perhaps part of that rather green and yellow some distance from the end, cut it down again to the plump bud you can find from 3 to 6 (Fig. 1) from the bottom; better to wait another year than irretrievably ruin your vines. But remember, once for all, although it is necessary to rub off the other buds, and train but one shoot, yet it must not be done until the shoot is fairly growing in the spring, for it sometimes happens that a shoot gets rubbed off accidentally, and if there is none to replace it the vine is spoiled.

But perhaps your vine has taken to the soil, and made a shoot 12 feet or more long, is at least as thick as your finger, and well ripened; if so, it is what a nurseryman would call a "good fruiting vine." But it is now absolutely necessary to inquire what sort of a house the vine is in. Suppose it is in a greenhouse where plants are required to be kept nearly all the year round, then your vine will have been introduced under a rafter, and must be kept there, and if more than one cane is required, a plant to each rafter is best, but there may be reasons why several cannot be planted, and one vine is to cover each rafter; if so, the vine must be pruned just at the bend, Fig. 2, a, the bud marked 1 to go up the rafter, and 2 and 3 right and left. The lower buds should be rubbed off, or they will grow and spoil the plants on the front stand; but suppose there is a strong young vine to every

rafter, then, if impatient to have fruit, cut it six eyes higher up, but remember that is not the way they get the large bunches we see at exhibitions; and as we are constantly asked "How do they manage?" we cannot do better than explain here. At the Crystal Palace show of Fruits and Flowers last autumn, was a bunch of grapes perfect in size, shape, and every property, weighing over four pounds, and in every way "better than a picture." It gained a first prize. Now the gardener who grew that held in his hand in the spring of 1861 just such a vine as we have under consideration—a fair-sized fruiting vine from a respectable nursery; he planted it into a bed (or "border" as the rooting place of vines is always called) specially prepared, introduced it into a vinery, and instead of having fruit from it, cut it back low down; soon the roots got hold of the good things provided for them, and in the autumn he had a splendid long rod reaching to the top of the house, which if cut back to ten eyes from the bend, would have carried ten good bunches of grapes, or twenty medium ones if left longer. But a few bunches

Fig. 1.

Fig. 2.

of grapes was no object, for he had plenty, and he also knew that it *always pays to wait*; so as he wanted a good bunch, he cut it back to a in Fig. 2, preserved one bunch and shoot, and had, in addition to a prize bunch, a rod that went to the top of the house and nearly down again, so that next year he will have a double row of bunches hanging from this, probably from two to four pounds in weight, and doubtless has another strong vine ready to bear its one bunch for exhibition.

We will now suppose that we have a vine under each rafter, and that some are intended to be cut as at Fig. 2, and others ten buds higher up. Of course our readers will at once see the propriety of cutting back the weak ones and leaving the strong, for it is only on those they can hope to get a dozen bunches of good grapes; and we would especially urge our friends to study the vines rather than an uniform appearance, and when it is not strong be content with six good rather than twelve insignificant bunches.

We must now consider the case of another class of inquirers—those whose vines are a year older, and who have had fruit this season. Now if they

have determined to grow on the rod system, a cane has been trained up the middle of the light from the front of the house (Fig. 3, B); if the rod has reached the top of the house, and is thoroughly vigorous and well ripened, then cut off the bearing rod at A, Fig. 3, and train the rod B in its place, cutting back

Fig. 3.

the short shoot below A to the first full round bud, from which the rod will spring for the succeeding year. But suppose, from insufficient root support, or over-cropping, or both together, the rod B is weak, and has not even reached the top of the house, or perhaps half-way, then by all means cut it back to the lowest eye, and trust for a crop to the old wood.

We have thus, in as simple a manner as we know how, given our readers an insight into *one way* of growing grapes; and while in vine culture it especially behoves us to "speak well of the bridge that carries us safe over," and we confess to having grown good grapes on this system, yet we do not follow it in general practice. We will state the advantages of the "long rod" system, and why we object to it. The first advantage is its extreme simplicity. The merest tyro cannot err—two strokes with a firm hand and sharp knife settle the business, and the pruning, about which folks are so nervous, and over which many old gardeners are so mysterious, is accomplished.

The second advantage is that if you get a good rod you are *sure of a crop*. Some of our readers will at once say, "Well, what more do you want, and what can there be to object to?" Now, unreasonable as it may appear, we certainly have two, to us, serious objections, and the first is that the rod shuts out a great amount of light while growing. In the regular vinery a due amount of shade is a *sine qua non*, but it should be produced by the foliage of fruit-bearing shoots, and not from laterals, rods, or anything else, more than can possibly be helped; but in the greenhouse or orchard-house of the amateur, where plants are to be studied as well as vines, any system that increases the shade is to be much deprecated, and even if the vines are to be trained under every other rafter, the objection still holds—the vines cover nearly *twice* the space they need. Our second objection is that the long strong rod is too frequently grown at the expense of the *existing crop*, and we believe this is the reason why nearly all our old and experienced growers have abandoned it. However well grapes may be grown on the rod system

here and there, our experience has been that with an ordinary crop, if the bunches have been large, the berries have been but medium-sized, and very frequently deficient in colour, thus proving that we were asking the vine to do too much; for when fruit that ought to be black is red, we shall nearly always find that it lacks other good qualities, and thus is very frequently watery, and comparatively flavourless.

The question therefore arises, can we not by a different system of pruning concentrate the strength that goes to form the rod into the fruit, so that we may get large, well-flavoured, good-coloured fruit. And this brings us to consider the "spur system."

This consists in cutting back the bearing wood to the last full round eye, or bud, half an inch to an inch from the main stem (A, Fig. 4). This plan answers very well for some time, and produces at least as good grapes as the long-rod system, without the objectionable shading, and is extensively practised among amateurs and gardeners in small places. But however careful the operator may be to "spur close," in the course of four or five years the old spurs form a zigzag, gnarled, unsightly mass, projecting at least two, and probably three inches from the stem; and these contortions and decayed stumps appear after a time to obstruct the passage of the sap, so that some of the spurs break very weakly, or refuse to break at all.

The usual and best mode is, when the spurs show signs of failing, to obtain a rod, as in Fig. 3, B, cut out the old wood at A, and start afresh. By this combination of the two systems, tons of good grapes are grown every year.

There can be no question but that old vines on the "spur" system present a heavy, cumbersome appearance when compared with a system which we will now consider, and which for simplicity we will call the "close-pruning" system. One method of keeping the old spurs "nearer home" is that the vine will frequently break back in the spur, sometimes pushing a shoot through two or three year old wood at the base or "collar" of an old spur; and wherever this occurs the pruner cuts the spur hack to this shoot, and thus gets rid of a year or two's ugliness. It is very probable that many gardeners, having pruned a vigorous young vine hack to the first bud or eye on the spur system, found the vine not only broke there, but also threw our shoots from the base or "collar" also, and that these shoots bore fruit, thus suggesting to some of them the idea of pruning "close," and getting rid of the spurs altogether. If a vine is carefully examined, it will be easily seen that at the junction of the young wood with the old there is a rim or collar, and that it is studded with embryo huds (see Fig. 5, A). Now the ordinary

old and unsightly spur; and, secondly, the system, like every other, has been injured by blundering disciples. For instance, in one case, a gardener who had been a successful exhibitor of grapes in a local horticultural society north of London, after seeing the Stortford vines, went home and cut off five-year-old spurs close to the stem, and of course, as there was no collar and embryo eyes to cut to, achieved a failure. But our readers must remember that they must close-prune at once, and if they have old vines with massive purblind spurs, they must get some young rods from the bottom, and close-prune for the future.

We have thus reviewed as simply as possible the principal methods of PRUNING the vine; and if we have a partiality for the latter plan, it is because it usually gives us several shoots with fruit on to select from, instead of being confined to one, as in the spur; and also because it saves time and trouble in the winter cleaning and dressing, for it is next to impossible to get the dead bark and wood out of the old spurs. But the intelligent cultivator will, if he has many vines, probably try all plans, for vines are planted not to bolster up systems, but to grow grapes; and he is a good gardener who gets good grapes, no matter what system he has adopted to obtain them.

Calendar.

WORK FOR WEEK COMMENCING JANUARY 12TH.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—There ought not to be now a single square yard of unoccupied ground that has not been deeply dug since the last crop was taken off. Deep stirring and successive frostings of the soil are immensely beneficial, and there will never be much success in the culture of edibles where there is any fear of hard work in winter. The outdoor work of this month must be regulated by the weather. When the ground is not fit to be trodden on, get together all the clippings of hedges, prunings of trees, &c., &c., for charring, and keep the produce under cover to use as useful; it is a most valuable top-dressing for peas and other early crops, both to stimulate growth and prevent attacks of slugs. During frost wheel out dung, ready to dig in at the first opportunity. Sow during fine dry weather, Sutton's Ringleader, Dillstone's Early, and Sangater's No. 1 peas, Mazagan, Longpod, and Beck's Gem beans, Horn carrot, and Hollow-crowned parsnips. We have found of late years that parsnips sown at the end of January make very heavy crops, and are rarely hurt by frosts; and if they do happen to be cut off by frost, there is still time to sow again, and the loss of the seed is a very trifling matter compared with the chance of a heavier crop.

ASPARAGUS PLANTATIONS to be marked out at once, and the ground dug two apits deep. A light sandy loam is the best soil for asparagus, but a soil almost wholly sand will be better than one wholly clay, because when heavily manured the sand will suit it admirably, but without plenty of manure will be useless. In a deep fertile loam a moderately heavy manuring will suffice, and the manure should be well mixed with the staple at least two feet deep. In any case the piece must be thoroughly well drained. If asparagus must be grown on a clay land, lay on six inches of sand or coal ashes, and dig this in to a depth of two feet, mixing it well with the soil, and let the ground rest a fortnight, and then dig again and liberally manure. If it is intended merely to sow for transplanting, a good manuring one full spade deep will suffice, if the second spit was previously stirred at a winter digging.

CAULIFLOWERS are apt to die off now unless kept dry; a little peat-dust will be useful to sprinkle amongst them where they are suffering from damp. Dry sand and wood ashes may be used for the same object. If the plants are crowded, they will only kill each other, so thin at once if necessary.

CABBAGE of all kinds may be sown on a warm border. The most useful to sow now are Shilling's Queen, Early York, and Roaette Colewort.

MELONS AND CUCUMBERS in the forcing pit to be kept carefully trained about nine inches from the glass, to be regularly stopped, and at a temperature of 70° by day and 60° by night. Sow now for plants to hed out in frames and pits, and for succession in the early forcing house. Our favourites for this season are—of cucumbers: Sutton's Berkshire Champion, Telegraph, Hamilton's Market Favourite, Carter's Champion, Lynch's Star of the West, Kirklees Hall Defiance, Butler's Empress Eugenie; and of melons: Beechwood, Carter's Excelsior, Cuthill's Scarlet Flesh, Egyptian Green Fleah, Trentham Hybrid, Turner's Scarlet Gem.

CUCUMBERS managed as advised in the calendars of the last few weeks will now be coming forward for bedding out. They should be kept in the house till they have filled 48-sized pots with roots, and then be planted. If kept any length of time starving in a pot-bound state, they will become infested with red spider, and weakened in constitution. When ready to plant out, the bed should be in a sweet condition through occasional forking over of the dung. The bed is to be made by laying some strips of turf, grass side downwards, in the centre of each light; on this put three or four bushels of soil in a heap, consisting of loam from rotted turves one part, leaf-mould one part, and dung rotted to powder one part. The third day after putting on the soil, put the bulb of a thermometer into the hillock, and if it registers 70° to 80° plant at once, if higher than 80° wait a few days longer. A fair average to start with is 75°. Plant in the centre of the hillock, and peg down the runners regularly, and shut close. In the course of a few days give air cautiously to let off any rank steam, and sprinkle the leaves frequently, but give only just enough water at the root to keep the soil moist until the plants have made a start. Choice sorts may be kept on from cuttings, to avoid the risk of deterioration. Plants that have been in fruit during the winter will furnish cuttings for succession, if the sorts are approved of for the purpose. Give air to plants in frames as often as the weather will permit. During mild weather, a little air may be left on all night, with a mat over the opening to prevent too cold a draught.

COLD FRAMES AND PITS.—Do not be in haste to remove protecting materials after a long frost. Let the plants recover themselves in the dark, and should bright sun follow suddenly upon severe weather, add some loose straw, to prevent the warmth reaching the stock too suddenly. Remove all dead leaves, and give plenty of air in mild weather.

Flower Garden.

IMPROVEMENTS AND PREPARATIONS.—We cannot advise the planting of evergreen shrubs at this season, though we confess to doing it ourselves; and seeing it done by everybody else. It would be much better for the trees to be content now with marking the places where they are to go by

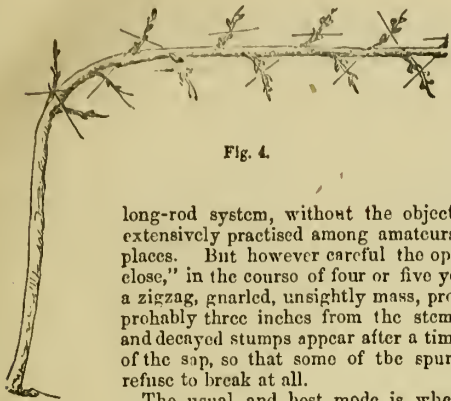

Fig. 4.

long-rod system, without the objectionable shading, and is extensively practised among amateurs and gardeners in small places. But however careful the operator may be to "spur close," in the course of four or five years the old spurs form a zigzag, gnarled, unsightly mass, projecting at least two, and probably three inches from the stem; and these contortions and decayed stumps appear after a time to obstruct the passage of the sap, so that some of the spurs break very weakly, or refuse to break at all.

The usual and best mode is, when the spurs show signs of failing, to obtain a rod, as in Fig. 3, B, cut out the old wood at A, and start afresh. By this combination of the two

systems, tons of good grapes are grown every year. There can be no question but that old vines on the "spur" system present a heavy, cumbersome appearance when compared with a system which we will now consider, and which for simplicity we will call the "close-pruning" system. One method of keeping the old spurs "nearer home" is that the vine will frequently break back in the spur, sometimes pushing a shoot through two or three year old wood at the base or "collar" of an old spur; and wherever this occurs the pruner cuts the spur hack to this shoot, and thus gets rid of a year or two's ugliness. It is very probable that many gardeners, having pruned a vigorous young vine hack to the first bud or eye on the spur system, found the vine not only broke there, but also threw our shoots from the base or "collar" also, and that these shoots bore fruit, thus suggesting to some of them the idea of pruning "close," and getting rid of the spurs altogether. If a vine is carefully examined, it will be easily seen that at the junction of the young wood with the old there is a rim or collar, and that it is studded with embryo huds (see Fig. 5, A). Now the ordinary

Fig. 5.

method of treating a young vine as there represented would be to spur it at B; but on the "close" system it would be taken clean off at C, close to the old stem, and nothing left but the embryo huds in the collar, and the closer it was cut without injuring them the better. In the spring, if the vines are healthy and vigorous, you will have from two to four shoots from each collar, and with many sorts the difficulty will be, not to get grapes, but to cut off and throw away as many bunches as you leave on the vine. We have pruned on this system for some years, and with unvarying success, as regards the different varieties of the Black Hamburgh and its allies, and the finer sorts of Sweetwater; and no doubt Mr. Rivers of Sawbridgeworth could in half a minute give the names of half a score first-rate growers who prune on this system; but it is sufficient for our purpose to get one illustration from his neighbourhood, and that shall be the vines of — Nash, Esq., of Bishop Stortford. Twelve or fourteen years ago, the grapes from these vineries carried all before them at the Chiswick shows of that day, and their fame was deservedly spread all over the country. We had the pleasure two years ago of seeing the same vines (as well as many others within a few miles of the same place) after at least ten years' close pruning, and saw a house of grapes that might be equalled, but could not be excelled; double rows of massive bunches hung from bottom to top of every rafter as regularly as though they had been tied on, and the gardener said he had taken off two bunches for every one left. The reason the system is not more generally adopted is, first, a want of confidence; the operator looks at the full eye on the spur, and then at the buds at the base, and makes up his mind that it is impossible that fruit can come from those little things, and so sticks to the

stakes, and leaving them untouched till April, when the shift will distress them less, and they will commence to make new roots immediately. This plan allows of the planting of deciduous trees and the finishing of all the rough work in laying out a shrubbery, and it may even be carried so far as to the making of the holes for the evergreens, laying the stuff taken out in heaps beside them to get completely pulverized for filling in. Every cultivator of flowers should secure now a good supply of turf from a loamy pasture, and of bog peat, or silky yellow loam in which the common brake grows plentifully. These should be stacked up in high ridges like walls, so that the frost will penetrate the whole mass, and the grass will rot quickly. Manure roughly spread among choice shrubs will assist in protecting their roots from frost. In spring the manure can be levelled, and all rough stuff raked off. This is a good time to make banks and rockeries, as during frost the wheeling can be done without harm to the walks.

Roses required to bloom early should be pruned now, but it is too early to prune the general collections.

DAHLIAS.—Now is a good time to get the ground ready, where these are to be planted out, by deep digging and ridging up, to have it sweet and pulverized when they are planted out in May.

HOLLYHOCKS.—Seed sown now, and placed in a moderate heat, will produce plants that will flower this year. There is only one caution necessary, and that is to beware of forcing them along too fast. We have known many instances of the plants perishing when about to open their blooms through too much stove heat in the first period of their growth. Shift from the seed-pans as soon as large enough to handle, and use a light rich soil.

AURICULAS.—Water very sparingly, keep the foliage dry, remove dead leaves, and guard against cold cutting winds. Give air at every favourable opportunity.

CARNATIONS and PICOTEES.—Keep them as hardy as possible, by taking off the lights whenever the weather permits. Much moisture would now do much mischief, but they must not get dust-dry. Turn up a few plants occasionally, and see if aphid has attacked them.

Fruit Garden and Orchard House.

FRUIT GARDEN.—Pruning ought to have been done and the ground cleared long ago. If not, set about it at once, for in the hurry of the general spring work, the huds may swell before the knife has finished its work, which is injurious. Trees on east walls had better be unnailed till the end of February, to keep them hack. Manure between the rows of currants, gooseberries, and raspberries.

VINERY.—Cover outside borders with a dry material. Set the first house at work at 45° to 50°, and increase the heat a little when the huds have fairly opened. In late houses paint the stems with a mixture of soap, sulphur, and soot, and give walls, rafters, and trellises a general cleaning before the vines begin to work.

PINERY.—Great care must be taken at this time of year to prevent injury by damp and sudden fluctuations of temperature. As we have now little sun, the general stock must be kept quiet by a moderate temperature. Young suckers potted off in the autumn will require a steady bottom-heat and air at all favourable opportunities. Day temperature for plants swelling fruit 75° to 80°, night 65°. Shift to fruiting-pots all the strong succession plants.

Greenhouse and Conservatory.

GREENHOUSE.—Hard-wooded plants must have fire-heat during frosty weather, but it must be given with caution, and must not rise above 40° at night and 50° by day. Hang strips of worsted netting over the ventilators to break the force of cold winds; this will allow more air to be given. Soft-wooded plants may be set going pretty freely, but be very careful not to have too high a temperature, which is most exhaustive to the plants. Examine all the old stakes used as supports to plants in pots, and if decaying remove them. The appearance of fungus on the part buried in the soil soon leads to the destruction of the plant, by contact of the white threads with the roots. Train and tie out whatever requires it; revise tallies and labels; keep down green-fly by fumigating; and complete all odd jobs, so as to have no hindrances to spring work when this month is over. Thermometer, 45° on an average, varying from 35° by night to 50° by day.

CINERARIAS.—These will damp off at the collar, or lose their foliage, if any accident occurs to touch them with frost or excess of moisture. This is the critical moment for them. Keep down mildew by the use of sulphur and admission of air. Remove decayed leaves, and tie out large specimens. Those showing flower may be put on a warm shelf; but the cineraria dislikes heat as much as it does frost.

PELLARGONIUMS.—Many will probably want repotting, which must be attended to. Select the plants intended for special purposes of exhibition or decoration, and give them plenty of room near the glass, and a temperature of 50° at night and 60° by day. Water with great care, and give air whenever the temperature outside is not lower than 32°. Those for summer blooming will do best at an average of 45°, but young plants that are not over-strong should have a warm place.

CALCEOLARIAS.—Herbaceous kinds that are pretty forward should be repotted, and have a little extra warmth. Shrubby ones will require stopping, but will do better in the ordinary temperature of the house. Green fly is sure to appear now, and must be checked in good time.

CAMELLIAS.—As they come into flower, treat them liberally. Keep the foliage clean with the syringe, or sponge dipped in tepid water. Keep them from fire-heat as much as possible. Azaleas treat the same, but give a little heat to those wanted early in bloom. Remember that sudden changes of temperature, exposure to dry heat, or too copious supplies of cold hard water, will cause the bloom-buds to drop. Force gently, and proportion the supplies of water to the condition of the plants. All hard-leaved plants, such as camellias, oranges, &c., should have their leaves sponged with tepid water.

NEARLY HARDY GREENHOUSE PLANTS.—These are invaluable to amateurs who are much away from home. First amongst them we place the Camellia. After this grandest of flowering shrubs, we have the Bottle-Brush, with its brilliant feathery plume of richest crimson, which only needs protection from the severest frost; the Cytisus, brilliant with gold in the early spring months; the Corydalis, which ten degrees of frost will not kill; the shrubby Veronicas, blue, lilac, red, needing only to be protected from the severest froons of winter; the lovely Plumbago capensis, with its thousands of turquoise-like flowers; the Chinese Primula, so nearly hardy, and now in flower delightfully; the Cyclamen Persicum,

lovely as sweet sixteen in its rosy blushes, and fragrant as the may; Epacris and Ericas, if we can only keep them from being soddened with damp; Azaleas in endless variety; Fuchsias, most shamefully neglected; and a few Ferns, such as Adiantum cuneatum, Asplenium bulbiferum, Davallia Canariensis, Nephrolepis exaltata, Pteris serrulata and cretica, Platyloma falcata, and Doryopteris sagittifolia. To make up the furniture, we can have zonal geraniums without end, for they will stand six degrees of frost without harm if dry and dormant.

Stove and Orchid House.

STOVE.—Be careful to keep down the temperature in general collections, and give air whenever the sun causes the thermometer to rise above the average. Plants that need pruning and repotting should be cut over, and left to start, before their roots are disturbed. Thermometer, 55° at night, 65° by day.

ORCHID HOUSE.—Prepare for potting as the season advances, and have all necessary material in plenty, and in a clean state. Chopped sphagnum, soaked in boiling water and put aside where no insects can get to it, fibry peat in blocks, crocks broken to three or four sizes, of which that nearly of the smallness of dust will not be the least useful, and good charcoal from which the dust has been sifted. When the plants are to be shifted, immerse them in tepid water one day previous, so as to wet the ball thoroughly. After repotting, fix the plants firmly to prevent rocking over, and place them in the warmest end of the house to encourage growth at once. The repotting should take place just as they are about to grow. The general collection must be kept in plump condition by sprinkling the floor of the house frequently, and at the same time allowing a slight rise of temperature. The syringe should be very sparingly used this month, but as the month advances there will be an increase of light, and a general tendency to growth will become evident. Brassias, Cyenoches, Cologynes, Miltonias, Sophronites, and Coryanthes are now beginning to grow, and may be shifted if needful. This is a good time to increase by division of the pseudo-bulbs any large specimens that are quite at rest. Dendrobiums are increased by cutting the old hulbs from the plant when they are at rest or just starting into growth, each piece being removed with a few roots attached, in the same way as an auricula offset. Old flowering hulbs, cut off without roots and laid on sphagnum in a warm and shady part of the house, will in time throw out roots, and may then be potted. After potting, keep warm and shaded, and give very little water until growth has commenced. Cattleyas for specimen culture should now be operated upon to produce "backbreaks." The process consists in cutting the plant in two between the hulbs; that is to say, there is to be an incision made, but not to separate the parts cut. After making the cut, let them remain in the same place; be careful that no water lodges in the cut, but supply plenty of atmospheric moisture, with a rise of the temperature. This will secure the formation of several flowering hulbs for the next season. Orchids newly received from abroad should be pushed into growth very gently. Epiphytes should be attached to their hocks at once, and should be hung head downwards; when they begin to grow, reverse them.

Literature.

The Intellectual Observer. Groombridge and Sons.—This elegant and ably conducted monthly is not only as good as ever, but in some respects better. The January number contains a beautiful coloured figure of the "Bell Bird" of tropical America, to illustrate a paper on the subject by Dr. P. L. Selater, Secretary of the Zoological Society of London. Another plate is occupied with life-like portraits of Zulu Kaffirs, and there is a most entertaining paper on Kaffir capabilities, by Dr. Mann. There are two papers on the Meteors of Nov. 13, 1866—one by the Honourable Mrs. Ward, the other by Mr. A. S. Herschel. Mr. Proctor contributes on the planet Mars, the Rev. T. Webb on Lunar details, and there are papers by Messrs. Rye, Birt, and others on results of scientific observation.

The Floral World and Garden Guide. Groombridge and Son.—The January number is full of variety, and is embellished with a large and beautiful figure of a rockery. The principal articles are on the Rockery, and Plants adapted for it; the Auricula; the Raising of Sub-tropical Plants from Seed; the Cultivation of Seakale; the Cultivation of the Chrysanthemum in Pots; Planting Strawberries in Spring; and a lively controversy between the O'Shane and Mr. Williams, of Ormskirk, on hardy herbaceous plants.

The Gardener. W. Blackwood and Sons.—This is a continuation of the *Scottish Gardener*, under the able editorship of Mr. William Thomson, of Dalkeith. The work has a very neat appearance, and the number before us is rich in variety, and is admirably done. The Editor contributes a paper on Flower Gardens, in which he dwells with persuasive force on the superior merits of beautiful and interesting features over mere gaudy displays of colour. Mr. McNab contributes an important paper on Pruning the Deodara. There is a commencement of a practical series on Strawberry Forcing; and a capital paper on Drainage. The Gleanings of the Month and the Notes on New Plants admit of improvement.

The Journal of Botany. R. Hardwicke.—Dr. Seemann does not contribute anything to the January number, but the Editor's absence is well compensated by Mr. Carruthers, whose able paper on Gymnospermata fruits from the secondary rocks of Britain is illustrated by four admirable lithographic plates. This is a charming paper alike for botanists and geologists.

The British Workman.—The Band of Hope Review. Partridge.—Few among the many periodical works sent us afford more pleasure than do the annual parts (they can scarcely be called volumes) of these two peculiarly attractive and entertaining broadsheets. The first is addressed to adults, the second to youth; the object of both is to promote temperance, good feeling, enlightenment, and practical piety. In carrying out his object, the spirited and amiable Editor does, we think, occasionally indulge in excesses, and make serious mistakes, but in a world where imperfections abound, we may forget the few scarcely visible blemishes of these works, and praise them with all our might for their conscientiousness of spirit, their wholesome variety, and their exceeding beauty. We talk of guinea volumes and first-class pictures, and in these penny sheets we find pictures equal to anything in the costliest issues of the press. Look for example at the reproduction of Mr. Fitzgerald's picture of "Independence," and is there anything to bent it in the way of wood engravings in the most pretentious publication of the day? Look again at Mr. Harrison Weir's

pictures in the juvenile book; the swan, for example, sailing before the wind with all the poetry of easy motion, and innate grace and dignity expressed by artful touches of the pencil. We do confess that we are astonished at these pictures, and we advise all our readers who are not possessed of them to order the parts of each work for 1866, and keep them on the table for a month or two to spread delight, and diffuse knowledge amongst all who see them. With each of these works is issued a sheet almanac, and these are superbly adorned with pictures; "Running down Hill," in the Band of Hope Almanac, really appears to be too good for the purpose; many a one will no doubt carefully eat it out and mount it in a serap book.

Old Jonathan. Collingridge.—The part for 1866 is equal to any of its predecessors, and in respect of illustrations somewhat in advance. This penny monthly broadsheet is well adapted for gratuitous distribution among the poor, its primary object being the spread of Gospel truths, and to mingle instruction with amusement for readers of all ages. It is peculiarly rich in anecdote, and is everywhere fresh and lively with lessons drawn from stirring events, and home truths inculcated by means of homely examples.

The Ladies' Magazine. 3, Amen Corner.—Mrs. Warren seems determined to leave no room for rivalry, by making this so admirably adapted for the entertainment of the women of England that they can have no alternative but to subscribe to it, and enjoy the intellectual treat it offers them. There are of course numerous papers and pictures elucidating the fashions and all sorts of fancy work, and there are original gatherings of facts and suggestions for every department of the household, but besides these things there is plenty of solid reading, such as to constitute the "Ladies' Treasury" a valuable family book. It may interest many of our readers to learn that in the January part there is a good account of the celebrated Arteaian Well of Grenelle, at Paris. The paper on the Theory of Dreams is original and profound. With this number is given a large coloured print representing a group of flowers. We could have wished the cost of the coloured print had been in some way expended on the pages of the magazine, for prints of this kind are of little use except to amuse for a few minutes, but a good woodcut illustrating a good story or bright essay, remains as a means of teaching and amusement for ever.

Our Own Fireside. Macintosh.—The January number of this excellent monthly is greatly in advance of former issues. It is the same in tone as ever, having for its object to refine and elevate its readers, and to display the breadth and beauty of religious truth. But there is more variety than heretofore, and more originality. We welcome the good-hearted Mrs. Ellis as the contributor of a story and some poems called "Songs of the Garden." Among the specially attractive articles there is a sketch of the Franklin Expedition to the Arctic Regions; a capital collection of Anecdotes of Dogs; and light sketches by the Rev. R. Maguire, Rev. S. Wainwright, and the editor, the Rev. C. Bullock.

The British Juvenile. Job Caudwell.—A new venture in the broadsheet style, very pretty, the matter admirably selected, the illustrations pleasing and appropriate.

The Gospel Magazine. Collingridge.—It has escaped our memory till now that the readers of the *Gospel Magazine* a short time since presented the editor, the Rev. D. A. Doudney, Incumbent of St. Luke's, Bedford, with a testimonial on the completion of the first centenary of the magazine, which was originally established in January, 1766. It is not the common fate of periodicals to live so long, and if we look about us we shall find very few indeed, either of newspapers or magazines, that have passed their hundredth year. In the present case the Editor's ability, application, and faithfulness have much to do with the general esteem in which the book is held, and with the sustaining of its name and fame untarnished as handed down to these times by the illustrious Toplady. There are all sorts of periodicals manufactured now for Sunday reading; some by so-called Christian writers, published under the auspices of so-called Christian societies, effect such peculiar combinations of love and religion and morbid sentimentality and cant, that we take leave to doubt if there can be a more effective agency for the degradation of religion and the inculcation of false ideas of morality and duty. Christian folks in need of hooks for Sunday reading, would do well to take the *Gospel Magazine*. It is all it professes to be; it is sound and true to Protestantism, it is entertaining and various, and tintured in every page with the love that lasts for ever.

ALMANACS FOR 1867.

The Farmer and Gardener's Almanac is again a wonder, both in respect of the quantity of matter and the beauty of the illustrations. We would suggest to its able editors to purge it of one vice, a vice common to garden almanacs, and that is the insertion of mere nursery lists under the head of "New Plants." The names and the descriptions are furnished for the purpose by the nurserymen, and they are but as advance sheets of their several catalogues. One of the year books we could name contains scarcely anything else in the way of information for the cultivator beyond what the trade has supplied, so that editing there is none (and that perhaps is no loss). With this exception the *Farmer and Gardener's Almanac* is a most valuable production, and it is especially so in the agricultural portion.

The City Diary is undoubtedly the best of all the diaries for business men. There is plenty of space for scribbling, and good blotting between, and at a moment's notice we can learn who is master of the Mint, or director of the aerial railway, or chief magistrate of the City, or alderman of Portsoken Ward.

De la Rue's Diary.—This is a fanciful book for the pocket and the desk; almost too slippery for common use, but well adapted for genteel people, and such as like everyday life to be embellished with red letters and true lovers' knots.

The Garden Oracle. Groombridge and Sons.—This issue of the Oracle slightly exceeds in bulk its predecessors, and has cost considerably more labour than usual in its preparation, which will account for its appearing late. To give any opinion upon its merits is of course impossible, but we may properly state what are its principal contents. The pages for the several months are filled with selections of the best fruits in all the several classes, making in all a list of about 500 choice varieties. The several selections are marked to enable the cultivator to select, say a dozen of the best apples or pears, half a dozen best grapes, pears, peaches, &c., &c. There are lengthy lists of gooseberries for show, with their weights, in 1866, and selections of the same fruit for flavour and for culinary purposes. The lists of new plants are derived as usual from the *Botanical Magazine* and the continental works; the lists of new flowers of 1866 are accompanied with descriptions, which in nearly every case are the result of the inspection of

the varieties by the Editor. This is the only garden almanac which contains independent descriptions and criticisms of new flowers; in all others they are supplied by the trade. A very important department is that devoted to selections for 1867. These have cost an immense amount of labour, and they are the most extensive and carefully arranged lists that have yet appeared in the Oracle. They comprise selections of hundreds, fifties, twenties, twelves, sixes, &c., &c., in all the classes of exhibition and decorative plants and flowers, and will no doubt be found of service to those who wish to grow only the best, and have no means of making comparisons for themselves, and who cannot afford to buy plants in order to pick out the best and throw the rest away. As the demand will be very great, we advise our friends to order the Oracle at once, as if the first impression (which is a large one) should run out quickly, some time must elapse ere a second can be got ready. To print a few copies of such a book, and so keep the market supplied, is next to impossible; or in other words, the proceeding would be attended with loss.

Colonization Circular, No. 25.—This is the report for 1866 by Her Majesty's Emigration Commissioners. It is a most important document to all who are interested in emigration. Those in want of it can obtain it from Messrs. Groombridge and Sons. The price is 6d.

CATALOGUES.

JAMES VEITCH AND SON, KING'S ROAD, CHELSEA.—*Catalogue of Garden and Flower Seeds for 1867.* This excellent list contains everything in request at this season; the arrangement facilitates reference, and there are some excellent woodcuts representing garden tools, meteorological instruments, &c., &c.—*List of Gladioli.* This is a single sheet on which the varieties are classified according to prices. All that are worth having will be found enumerated and described.

SUTTON AND SONS, READING. *Amateur's Guide for 1867.*—This admirable publication is as brimfull of valuable information as ever; all the selections have been revised; and in respect of cultural advices it is all it professes to be—a genuine "amateur's guide."

A. VERSCHAFFELT, 50, RUE DE CHAUME, GHEENT. *Catalogue No. 79 for Spring 1867.*—This is M. Verschaффelt's small yellow-paper list crammed full of stove, greenhouse, and hardy subjects, and comprising a few novelties of importance.

SMITH AND SIMONS, BUCHANAN STREET, GLASGOW. *Descriptive Catalogue of Hybrid Gladioli.*—This includes the newest kinds, and all are described with care.

W. WOOD, WOODLANDS NURSERY, MAREFIELD, NEAR UCKFIELD, SUSSEX. *Catalogue of Seeds and Bulbs for Spring planting.*—An excellent trade list, very nicely got up, and comprising everything needful for spring sowing and planting.

JAMES CARTER AND CO., 237, HIGH HOLBORN. *Gardener's and Farmer's Vade Mecum, Parts 1 and 2, 1867.*—In the first part there are 90 close pages occupied with lists of flower seeds and ornamental plants, and practical essays on the art of raising plants from seed, and on the subjects which may be safely selected for various styles of garden embellishment. In the second part there are fifty pages occupied with lists of seeds for the kitchen garden and farm, and woodcut representation of several novelties. Amongst the latter, the following deserve special mention: *Sims's Mammoth tomato*, a large fruited variety of the cherry tomato. The *Ashtop Fluke* potato, an excellent kidney shaped variety, the result of a cross between the fluke and the old ashleaf. *Bromus Schröderi*, the new and valuable "Australian grass," which is coming into general use as one of the best forage plants in cultivation, especially to furnish early feed before the rye grasses are in condition.

JOHN SCOTT, YEOVIL, SOMERSET. *Catalogue of Flower Roots.*—A good list of bulbs with selections of Achimenes, Gloxinias, Liliums, Alstrœmerias, Violets, and various garden requisites.

FREDERICK GEE, BIGGLESWADE, BEDS. *Catalogue of Agricultural, Garden, and Flower Seeds.*—A capital list, so arranged as to serve for customers to order what they want with an infinitesimal amount of trouble.

Correspondence.

PRESERVATION OF TEMPERATURE.—With pleasure I read the leading article of your valuable GARDENER'S MAGAZINE of December 29th, 1866, on the preservation of temperature. I am happy to state that I quite coincide with your opinion, namely, that the construction and heating of houses are matters that lie at the heart of our practice in every attempt to cultivate fruits and plants. It is a subject that has occupied the attention of many eminent horticulturists from time to time to endeavour to find out the best and most economical means for the preservation of temperature. In the more exposed situations of the northern counties of England, the object of protection may probably demand more careful consideration and attention than in the southern counties, to grow and protect plants introduced from a warmer climate. I often found, years ago, our ordinary method of covering plant pits, and small houses and structures, with bass mats, where plants were placed to remain over winter, with little or no fire-heat, was in many instances incomplete. Many times in winter and early spring months, the winds are so strong and boisterous that it is almost an impossibility to keep the glass covered. I was at length, therefore, led, without ever hearing of the plan, to place my mats, or covering, *inside the glass*, instead of outside. I found it in severe frosty weather a capital plan. Spare lights, employed for cucumbers, &c., in summer, placed inside along the lower part of the roofing, answer a good purpose for preserving temperature, and protecting the plants beneath from becoming frost-bitten. The covering over the glass outside often becomes saturated with wet, and if followed by an intense frost, the glass and covering become, as it were, a complete mass of ice, and also, if very windy, half of the covering is blown away or removed. Now nothing of this kind takes place when the covering is neatly placed inside. The preservation of the vital principle of plants, and the stimulation thereof to the functions of active operation, depend upon the agency of heat. It would be well if we northerners could gain more perfect knowledge on the elaboration of the sap and distribution of the vital secretions, and other wonderful phenomena of vegetable life, and also of the laws of conduction and radiation of heat, and evaporation of fluids. Of all these things we know but little, and may with propriety confess our ignorance of the laws and regulations of this most interesting part of natural operations. I do not know if you have ever been presented with a communication of this kind out of this county, but I have read your magazine several years, and never recollect an article out of the county Durham.

A. D. ALLASON, Bishop Auckland.

DOES COCOA-NUT FIBRE INJURE GARDEN SOILS?—I am the victim of divided opinion, and I must trouble you to solve my difficulty, as I have always found you do with ready kindness when I have got into a dilemma. I have for many years in the winter (living in London in a north-east aspect) put over my bulbs *more especially* a thick coating of cocoa-nut fibre refuse, likewise on the borders, to save any hardy things that can be saved by its warmth. My bulbs have always done especially well: hardly any loss, and good flowers. I have likewise, in potting, over my crocks put a good handful of the refuse, as I think the roots like to work in it, and the worms and vermin are not fond of getting through it. All this I did under good advice, and I have not yet doubted its benefit, or lost faith in it. I am now told by a party whose assurance might constitute authority that I have ruined my garden by using the fibre, as it deteriorates the ground to that extent that nothing will ever grow in it, and quotes my not succeeding with my bedding plants last year as a proof of it, baving, he says, nothing but foliage upon my geraniums, calceolarias, verbenas, &c., &c. It must be a fine summer indeed in my aspect, surrounded on all sides by houses as I am now, to hope for much from my bedding plants—last year especially; but I acknowledge my conversion to the O'Shane's opinions, and am trying to convert others; that we need not give up gardening because bedding plants won't do more, especially in the unsatisfactory way we obtain them from the nurseries. I say you may as well to-day pick up a native of Calcutta as he is basking by the Hooghly, and, *hey presto!* drop him on the ice of the Neva, and expect him to like it; but that is far from the purpose. Please give your opinion on the fibre question.

NE QUID NIMIS.

[We print this letter in order to raise the question amongst our readers whether the constant addition to the soil of a garden of cocoa-nut fibre refuse in the way above described does tend to the deterioration of the soil. As we are asked to give an opinion, we say that we believe most garden soils would be improved rather than deteriorated by the addition of the fibre to the staple, for it contains no innocuous property, and must produce in the process of decay more or less of carbonic acid, the presence of which in a soil is promotive of fertility. That our correspondent had a poor display of bedding plants last summer may be as well attributed to the unfavourable weather as to the fibre, for certainly the summer ended with the month of July.—Ed.]

GROUND VINERY.—I have a newly made border about 24 feet 6 inches by 8 feet 6 inches, lying against a south wall: the west end bounded by a path, but the east end by a wall and fence about 9 feet high. Being anxious to make the most of the space, and at the same time to secure the best advantages for the vines, I have thought, after some deliberation, that the best plan will be to plant four vines (Black Hamburgs) at the west end, and train them in two vineries the whole length of the border, leaving a narrow path between the two. This will give a run of 96 feet and secure to the vines the early sun. By planting against the wall, or in front, much space would be lost and more vines required. However, I should be glad of your advice as to which or what plan is best. Then, too, I have thought whether two vines under a 42-inch vinery would do so well as one under a 30-inch vinery. I should mention that there are some vines at present against the wall, which, if the vineries ran from west to east, might remain, but they need not stand in the way of a better plan.

AMATEUR.

[Plant at the west end, because of the path there, which enables you to reach the foot of the vinery without making any alterations. The best economy of space will be to have four vines in two vineries; you have fair space for three lengths of 7 feet each, and when needful you could have a half length made so as to carry the rods, to the extreme end. There is no more difficulty in taking two vines along a 42-inch or even a 36-inch frame than in taking one along a 30-inch frame: they are always kept to single rods.]

RECORDS OF THE WEATHER AT WOOLSTON, NEAR SOUTHAMPTON.—Sunday, Dec. 30th, weather began to get colder, wind W., and threatening distant electric clouds; lightning after 8 p.m.; bar. fell from 29.04 to 28.90. Monday (last day of 1866), hard frost, cloudy, snowy, electric "nimbus," calm, and cold; bar. steady, 28.90; eve, came in sharp frost, with masses of cumulo-cirro-strati clouds, sinking along S.W.; wind E. to N.E. New Year's Day, hard frost, fine, very cold, N. wind, rather cloudy; p.m., calm, cirro clouds; night, hard frost, but falling barometer (indicating a downfall), overcast at 11, then risen; heavy snowfall before morning, strong wind. Jan. 2nd, bar. down to 28.67, overcast, strong wind driving the snow about, about 7 inches deep, some places knee-deep; p.m., cleared up; eve, severe frost. Jan. 3rd, intense frost, overcast, cleared up about midday—splendid scene, bright sun, and dazzling snow-clad earth; bar. rising steadily; night, frost intense. Jan. 4th, intensely cold, calm, cloudless; it then steaming, and some ice floating about; p.m., cumuli clouds bordering S.E. to S.W.; night, cold greater than night before at same time, but looks on the change; cloudy at 9. Jan. 5th, overcast all day, slight thaw, almost a gale S.E.; night, gale and sleet. Jan. 6th (Sunday), a thaw, and its accompaniments, warm, foggy, rainy. Jan. 7th, warmer, gale S.W., rain at times; bar. very low, 28.80. In the following table I give the lowest and highest temperature in air, and lowest on snow (or grass).

	Min. Air Lowest.	Min. Snow Lowest.	Max. Air Highest.
Dec. 30	34°	—	43½
" 31	28	21° grass	37½
Jan. 1	28	20½ "	32
" 2	24	16½ "	28½
" 3	14½	4½ SNOW	31½
" 4	7	2 "	29
" 5	14½	5 "	36½
" 6	34½	32 "	46½
" 7	43½	34½ grass	*53½ *46!

See what happens in a week! Now it's like it used to be a few days ago, warm and rainy. We know not what may occur before next Monday—perhaps cold again.

FRANK EKLESS.

Replies to Queries.

Primulas.—W. H.—There are several named varieties with stripes and blotches on white ground. Yours are beautiful, but not novel. You would do well to cross the best of these with pollen from dark flowers.

Woodlice in Outdoor Fernery.—Bonchurch, Isle of Wight.—The fernery being made of blocks of limestone rock, affords abundant shelter for these vermin, and all outdoor ferneries are similarly infested. There is but

one way to deal with them, and that is to trap them, and if this be vigilantly followed up, every woodlouse may in time be destroyed. Something may be done now by lifting any blocks that are moveable, and killing all snails and woodlice that are found. But the serious task of trapping must be deferred till spring. Then place near their haunts wooden boxes or flower-pots filled with dry moss and lettuce leaves, or slices of potato or apple concealed amongst the moss. They will scent out these dainties, and take up their abodes amongst the moss. The traps should be examined every morning, and the vermin found in them should be at once killed. They will take shelter in any place that is *dark and dry*, and may be almost as easily trapped without baits as with them. We had occasion to regret the increase of woodlice near a border in which small seeds were sown last year. Some large sheets of bark were stripped off some trees that had been felled, and these were laid hollow side downwards near the haunts of the woodlice. In the course of a few days, the bark was crowded underneath, and the vermin were swept off it and destroyed wholesale. In the course of a fortnight the bark trapped them all, and the border was ten times more valuable than before as a seed-bed for lettuce, broccoli, &c. &c. We much regret the delay in replying to your letter.

Removing Roses and Carnations.—A. E., Notting Hill.—The roses and carnations you have purchased may be removed any time during the winter, provided that, at the time of removal, the weather is not frosty. Of course they must be at once planted where they are to remain in their new quarters, or if the place is not ready for them, pot them.

Books.—J. A.—Mrs. Loudon has published an excellent book on the cultivation of bulbs, which you can hear of through Messrs. Bradbury and Evans, Whitefriars. Messrs. E. G. Henderson and Son, of St. John's Wood, published a few years since a useful work on the subject, which, however, did not pretend to rank as an important literary production.—J. Simson.—You will find all the information you wish in rotation cropping of the kitchen garden, in "Profitable Gardening," the price of which is 3s. 6d. In the management of a small flower garden, no better guide than "The Town Garden," published at the same price.

Ericas.—Old Subscriber.—The following are twelve good ones to flower from November to February: Pucbella, Syndriana, Ardens, Hyemalis, Sebana lutea, Formosa, Wilmoreana, Mammosa, Decora, Prestans, Triumphans, Coccinea.

Cinerarias.—Old Subscriber.—The following are twelve of the very best (not including any of the newest): Captain Schreiber, Celestial, Constancy, John Spencer, Lord Elgin, Midshipman, Novelty, Optima, Perfection, Premier, Queen Victoria, Vicar of Caunton. We have made a very careful selection of these in the "Garden Oracle."

Material to prevent Drip under Stage.—Tyro.—Plants put under the stage of a greenhouse usually require a little light, and there is generally enough light for fuchsias, ferns, and other subjects during winter, and the drip caused by watering does them no harm. The only material well suited to prevent drip is zinc, with one edge turned to form a gutter, and placed so that the water falling on it will flow away to one end where it can be caught. In many instances we have seen elegant conservatories kept dry by means of a zinc catch under the shelves, but it is seldom needful in greenhouses, and besides it excludes the light from the plants that are placed under the stage.

Dahlias.—W. Moore.—Add the following twenty-four to those you have Miss Pressley, White Perfection, Helen Potter, Norfolk Hero, Bullion, Master of Arts, John Keynes, Disraeli, Lord Palmerston, Triumph de Percq, British Triumph, Scarlet Gem, Lord Clyde, Foxhunter, Marquis of Winchester, Empress of India, Duke of Wellington, Erebus, George Rawlings, Baron Taunton, Juno, Marquis of Bowmont, Lilac Queen, Freemason, Arrah na Pogue. You do not say if you want fancy varieties, and we have selected only from the show classes. It will be well to consult the new selection of Dahlias in the "Garden Oracle," as they are all marked for distinctive purposes.

Potatoes.—Agricola.—Webb's Imperial and Dawe's Matchless are the same, but Cheshire, Pink-eye and Pink-eyed Kemp are, we believe, distinct.

Magnifying, &c.—S. S. S.—In the remarks to which you refer no names were mentioned; therefore there is but a general case for consideration. The rebuke was a wholesome one—likely to do good, but incapable of harm. Your letter is equivalent to a personal attack, which is uncollected, and can serve no useful purpose. The picture of the rose at page 546 of last year's volume was sketched from the life by Mr. Damman, one of the most able artists in London. It undoubtedly represents a well-finished specimen fit for the exhibition table, and every practical cultivator will value it as a model. A figure of a scraggy, ill-furnished plant could be of no use except to show what is possible where skill is wanting.

Hoya carnosa.—R. W. W., Clapton.—Your plant is the noble Hoya carnosa, a first-class twiner for the stove. The plant requires a mixture of one part each of fibry peat, silky loam, and pounded brick, and a half part of silver-sand and charcoal dust. During winter, keep rather dry and cool, say not more than 45° on the average; in summer, above heat, and all the sunshine possible. This plant looks charming when trained to the roof above the level of the eye.

Examination of Gardeners.—D. D.—The matter was explained at length in the GARDENER'S MAGAZINE of Dec. 9, 1865.

Pomponc Chrysanthemum.—R. J. Chapman.—Your seedling pomponc is extremely neat, chaste, and pleasing, the colour bluish deepening to soft pink. It is in the style of "Fairest of the Fair," and appears quite suitable for cultivation in the specimen form.

Pruning a Vine.—Green Amateur.—Nothing can be more simple than the pruning of your vine. Shorten the leader to about six eyes beyond the topmost lateral, of which in your sketch there are four. Then cut each of those laterals clean away to one eye, or, in other words, leave only one eye of each lateral.

THE ONLY ORIGINAL GARDEN ALMANAC IS THE GARDEN ORACLE, edited by SHIRLEY HIBBERD, Esq. The descriptions of new flowers and fruits are from observation, and have the guarantee of personal responsibility. In other works of the kind the descriptions are supplied by the dealers: in other words, the descriptions are advertisements in disguise. The faithfulness of the Oracle in statements of fact, and its well proved soundness of opinion, have secured for it universal approbation. The issue for 1867 contains a quite new Selection of Fruits, and very carefully prepared Selections of Plants, Flowers, &c., for home decoration and exhibition. Order the GARDEN ORACLE for 1867, price 1s. Groombridge and Sons.—[Adv.]

The Gardener's Magazine.

SATURDAY, JANUARY 19, 1867.

THE MANCHESTER EXHIBITION progresses so well that already above 120 persons have become guarantors to the amount of £20 each, making a total guarantee fund of £2,400, which it is expected will be increased to £5,000 by the 1st of June next. By a slip of the pen, in our remarks last week we stated that the Bury show would clash with this. The fact is, the Bury show does not take place till July next (15th to 19th), and moreover the date of that affair is fixed by the Agricultural Society. The patronage of Bury by the Kensington Council is therefore by no means a mischievous proceeding, though as a bit of trifling it may have in it some ludicrous features. The capacity of the society for mischief is really greater than we represented it in our leading article of last week. The society's own show has been ingeniously arranged with a view to rob Manchester of some of the lustre that belongs to it of right, having fixed the date of the National Exhibition long ere the deliberations of the Council of the Royal Horticultural Society had carried them so far as to determine to hold a show at all. The Manchester Exhibition is to open on the 7th of June, and continue to the 15th. The great show of the Royal Horticultural Society is open to at Kensington on the 4th, and continue to the 8th, so that it will be impossible for the same plants to be shown at both exhibitions. It will be perceived that the case is much worse than we represented it last week. The Royal Horticultural Society, in its zeal for horticulture, will, if it can, cripple a great project intended for the promotion of horticulture in one of the most populous and wealthy manufacturing cities of the north. "If it can," we say, but fortunately it cannot, for long since many of the best plant-growers of the southern and midland counties promised to support the Manchester project, and will assuredly keep their word. There is only one thing the society can do effectually in this matter, and that it has frequently succeeded in. It can make itself look as mean and ridiculous as it is in reality; it can display all the paltriness that underlies its very superficial grandeur; it can wage a war with Manchester with the certainty of being beaten; it can betray the desire for mischief, and its utter incapacity for accomplishing it. That we were not better informed on this subject last week, admits at least of this excuse, that there is always great difficulty in ascertaining the truth about any movement inaugurated or favoured by the quasi-horticultural people at Kensington. For example: on Tuesday last we received the "Proceedings of the Royal Horticultural Society, No. 6, new series, August 1866 to January 1867"!!! Since July last we have not heard officially of a single spasm that has affected the Kensington Council, and now a shabby little Catnach sort of print comes to hand containing 16 pages of information on the affairs of the society, such information actually dating from the 15th of May last. Any mistake about the intentions or accomplishments of a society which communicates with its members at intervals of six months is excusable, and indeed we prefer to know very little of its affairs, and should not have devoted all this space to remarks upon it except to put our friends on their guard against being led astray by the movement set on foot at Kensington for the injury of Manchester.

A TASTE OF REAL WINTER is almost as welcome to the masses of the people as such a rare occurrence as a hot and enjoyable summer. People who thought Nature had altered her ways in respect of weather in England, are now reassured, finding in seasonal frost and snow some evidence that Nature is not utterly and hopelessly deranged. To all who are directly interested in the affairs of rural life, the recent frost has been a welcome event. The general opinion is that it will be followed by important benefits, especially in respect of the vegetable produce of the season forthcoming. There does not appear to be any immediate and necessary relationship between a cold winter and a fruitful summer, and possibly if we were to investigate the records of a century, we should find as many fruitful summers following mild winters as the reverse; and the popular notion that "frost kills the vermin" is certainly as erroneous as any popular notion can be. Generally speaking, insects are well taken care of, and have means to take care of themselves in winter, so that, as a rule, frost destroys but few of them. That frost operates beneficially on the soil admits of no dispute. Frost and snow are admirable fertilizers; they "burst up" mineral masses, and present an infinitude of fresh surfaces to the disintegrating action of the

atmosphere, and thus feed the soil out of its own resources with silica, potash, calcareous salts, and other ingredients requisite for the growth of plants. Those who followed the oft-repeated advice to dig deep and ridge up all vacant plots of ground before winter, will now be benefited by the pulverization of the soil, and its enrichment with materials newly reduced to a condition suited for appreciation by plants.

The first frost of the year came suddenly, and lasted but a short time, but was excessively severe. On the 2nd of January the snow fell heavily, on the 3rd frost set in severely, on the 4th (the dreadful Friday) the thermometer registered in many places 26° of frost, and in every one of our great towns the atmosphere was so loaded with coal-smoke, that breathing became difficult, even for the robust, and many thousands of weak and aged people received their death-blow. Never before has the present generation passed through such a trying day. The cold was keener on the night of Christmas 1860, but it made a less terrible mark in the bills of mortality than did the cold, combined with fog, of January 4, 1867. The long lists of deaths in the *Times* newspaper, for several days following, afforded indication enough of the havoc made amongst the aged and infirm. On the 5th the temperature rose steadily, and the barometer fell, so that in London it had ceased to freeze by about 4 p.m., and weather-wise people knew a storm was brewing. On the 5th (Sunday) the heavens rained a deluge, the snow was washed away, and the face of the earth was prepared for the kind, but firm and enjoyable frost that followed, and which has not yet proved particularly severe, 14° to 18° of frost being the extreme point reached in the descent of the thermometer.

It is perhaps premature to inquire what harm has resulted to the vegetable kingdom from the two visitations of severe weather. As far as can be judged by the present appearances of things, the first exceedingly severe wave of cold has inflicted a comparatively small amount of damage upon the fields and gardens. The snow which preceded the frost protected vegetation, and many comparatively tender subjects have escaped apparently unhurt. That Brussels sprouts and broccolis should be destroyed in all the gardens on the cold soils of the north of London was to be expected. Such things are always swept away by a sharp frost in those districts. We have made a rough inspection of several comparatively tender trees and shrubs, and they appear to be scarcely at all injured. In the fatal winter of 1860-61, *Grislinia littoralis* was destroyed root and branch, though well established in a sheltered border. Some nice plants of it in pots which have been plunged in a border with other choice evergreens are now almost as green and fresh as they were before the frost commenced. We attribute their escape from the frost of the 4th to the fact that they were heaped over with snow, for we added to what fell upon them and buried them entirely. So the rather scarce and tender *Berberis Fortuni* appears to be unhurt. The plants of this were treated in the same manner as the *Grislinia*. When the winter is over will, however, be the proper time to take correct measure of the effects of the recent frost, and we quit this subject in order to cast our thoughts upon the future.

At the time of writing this (Thursday noon), a sharp north-east wind is howling amongst the trees, and the frost holds its own very steadily. A little sleet-like snow has fallen, and the landscape is agreeably whitened. It is a question of equal importance and interest, "Will it last?" We fully expect that before this sheet is printed the frost will for the present be past and gone; and instead of skates for the feet, umbrellas for the shoulders will be in request. But whether it holds to the end of the week, or pass away while these remarks are in course of printing, we fully expect that a few days at the utmost will complete the present reign of King Frost, and that the interregnum, ere he again wields the sceptre, will be characterized by every possible meteorological misery, amongst which snow and rain will be the predominant features.

THE DOUBLE PETUNIAS.

When the flower garden is in full bloom, then it is that, almost as a rule, the houses are but scantily supplied with attractive subjects. And why? Because the outdoor attractions, combined with the season, are more inviting; yet withal there is something very pleasing in leisurely walking through a well-furnished house of blooms in the summer and autumn months—the same being effectually screened from the scorching rays of a hot sun, thus reflecting a nice soft and subdued light on the plants. At one

period of gardening when Pelargoniums had ceased to bloom there existed an ambition among gardeners to rival each other in the growth of the Balsam and Cockscomb, but the cultivation of these favourites has almost become a thing of the past, the Fuschia having to some extent superseded them. Yet there must be variety; and nothing is finer or better adapted for that purpose than Double Petunias, because they present to you some lovely shades of colour, including pure white, purple, blue, mauve, crimson, blush, and others. Some of the varieties are highly fragrant. Of course their habits and constitutions vary, some being particularly robust, while others, on the contrary, are weak in growth. But there is one thing in their management must be guarded against in the earlier stages of their progress, and that is to check any tendency to lanky growth by frequent stopping and pinching the side-shoots. Every encouragement should be given to produce a bushy plant, as the closer the shoots are to the base of the stem, the more likely are you to preserve your old plants throughout the winter, if you are desirous of doing so. As most of the Petunias, both single and double, have a tendency to shank or wither midway of the stem, betwixt the surface of the pot and the lower shoot, I have from practice proved that the more the lower portion of the stem is furnished with shoots, the less liable it is to incur the evils complained of. During this month and February is a good season for propagating them. If done in the autumn, it would be better, as they would, if now potted from their nursery pots into single pots, submit to being pushed on in their growth as soon as they are established in the pots, which can be hastened by plunging them in a mild bottom-heat. But avoid too much top-heat, as they will grow fast and weak, and the consequence will be that a great number of the shoots will become too spindly, and thus dwindle away, so that no after-treatment will restore to them the necessary vigour. Fast growth, when subject to heat, induces them to become a ready prey to the attacks of green fly. However, under all circumstances, fumigate them at frequent intervals, if you wish to preserve their health. As with the Fuschia so with the Petunia, there is always some improvement on the varieties already in existence being introduced; and although you may wish to preserve the stock which you now possess, yet it is advisable to purchase a few varieties every year, and thus by comparisons you will be led to discard some of your old favourites. It is a very good season now to make choice of them, as they are to be had at the principal nurseries. In passing through a large nursery at Holloway during the past week, I observed several batches of them in small 60-size pots, treated on the plan now advised for future culture. Such plants, if encouraged by liberal treatment, would by the next autumn fill an eight or nine inch pot, and produce a very gorgeous effect in the conservatory. Where cut flowers are in great demand, they are excellent plants to cut from, as they are good substitutes for rose blooms when the latter have past their best, particularly if required for decorating epergnes or large vases, as they maintain their freshness for some time after being cut. In potting, I prefer a firm soil—that is, some nice mellow loam, with sufficient leaf-mould or decayed manure to impart their nutriment to the plant, and adding some silver-sand—enough to keep the soil porous. With the Petunia, as with the Primula, the firmer they are potted the better are you enabled to keep them throughout the winter months—especially old plants; and here other attention is required, such as picking off any decayed leaves, &c., so as to prevent them from damping. Place them in the highest and warmest corner of the greenhouse, and water them but sparingly during the winter months.

JOHN F. M'ELROY.

PEASANT PROPRIETORSHIP IN FRANCE AND BELGIUM.

A writer in the *Pall Mall Gazette* asks: "But has peasant proprietorship answered so well in France and Belgium as to encourage us to introduce it in a land far less suited to it, and in which we have already had so terrible a warning of the danger of maintaining a large population wholly or mainly dependent on the produce of the soil? We will not prejudge the question, but let those who think so ponder the following figures. By one of the last returns we can lay hands on, there were 7,846,000 proprietors of land in France, and of these 3,000,000 were so indigent that they were unable to pay even the very moderate land-tax imposed on ownership. Such are the mad prices given by the people, owing to their mad passion for possession of the soil, that in many cases their lots yield them only 2 per cent. on the purchase-money; two-thirds of them are mortgaged nearly to their full value; and so difficult and costly is the transfer (in consequence partly of their smallness and partly of their indebtedness), that the legal charges on the sale of land sometimes reach 75 per cent. on the value. In Belgium, the facts are almost as significant. According to semi-official returns, there were, in 1857, 908,000 families in that country (averaging five persons each). Of these 89,630 were in good circumstances, 373,000 in straitened (*pénible*) condition, and 446,000 in actual poverty. This does not look well for peasant proprietorship even in a country where the climate is much better and the waste land much rarer than in Ireland. In fact, Belgium, though in many respects prosperous and well managed, abounds in pauperism. Out of a total population of four millions and a half in 1856, there were 86,000 known and habitual boggards."

A FEW WEEKS IN NORTH WALES.

AN EXCURSION FROM CYNWYD TO PYSTYLL RHAIADR.

This is the most celebrated waterfall of the country. It is situated near the boundary lines that divide the counties of Denbigh, Montgomery, and Merionethshire. The route I was obliged to take was over the Berwyn Mountains, an immense range extending fifteen or sixteen miles. Half of this distance completed my journey to the cataract. It was not the waterfall alone that induced me to take this journey; I had another object in view, that of searching after rare and beautiful plants, many of which I expected to find on my way. My expectations had been greatly enlarged by spending an evening with a Mr. Hugh Puig, a gamekeeper in Cynwyd. This person is a good botanist, and knows every plant that grows on this mountain. He showed me a fine collection of dried specimens, correctly named; and, by-the-bye, he has promised to take me and show me where a patch of the Maidenhair fern is growing in its natural state. He showed me a variety of interesting ferns that he had collected in the neighbourhood. Wherever his wanderings may conduct him, whether over the mountain or in the valley, he is equally at home amidst the beauties of the vegetable kingdom; and through all the changes of the seasons he meets with friends whom successive years have brought to his acquaintance, who, though silent to the casual observer, are always eloquent to him. There was something indescribably cheerful in his open countenance when he was talking about these little mountain plants. I could not help smiling at his enthusiasm. "I have to travel a great many miles in a week through the woods and over mountains, but it does not matter where I go, Nature presents an inexhaustible fund for contemplation and delight," said he. I thought if the productions of the vegetable kingdom excited such emotions, and a close acquaintance with Nature's works contributed so directly to human happiness and the exaltation of every noble feeling, as evidenced in the case of my aged friend, we ought to try to encourage a taste for those pure and simple pleasures. Such studies are not only suited to every time, to every age, and to every place, but give strength in youth and joy in old age, and adorn and delight us when we walk abroad.

At my outset, the morning was serene, the air fresh and crisp; everything seemed to partake of a general sprightliness. The whole scene was enlivened by the notes of the blackbird, echoed from among the distant foliage. I could almost fancy it was May instead of December, and I am sure the general greenness and beauty of the mountains would have interested a less ardent admirer of the works of Nature than myself. These rural objects continued, however, for a very short distance, for after I had walked about a mile and a half from Cynwyd, continually climbing higher on the mountain, I began to leave the homesteads and their peaceful occupants behind, and then entered on a succession of dreary open moors, which might have charms for the sportsman, but they had none for me. For three or four miles the scenery is wild, dreary, and comfortless. As I ascended, the moors became more swampy, walking began to be very unpleasant and even dangerous, for the swamps were covered with treacherous mosses, such as *Funaria hygrometrica*, *Bryum serpyllifolium*, *Sphagnum palustre*, *Dicranum glaucum*, and many others. These made tempting green walks to look at, but hollow ground to tread upon. The peat bog had accumulated to an enormous depth; the thickness was made visible by the gullyholes that had been formed by the mountain storms and torrents. I now came in sight of the Great Berwyn Rocks. These I was informed, before I started, were near the waterfall. The two most elevated summits are Cader Ferwyn and Cader Fronwen. I was anxious to get to one of those high points, as I anticipated an extensive view; but to ascend its summit appeared a most arduous undertaking, and indeed I found it so. After mustering all my resolution, I commenced the laborious task, and after continuous climbing and frequently slipping, using my hands, my knees, and the points of my toes as the agents of propulsion, I attained the highest part, and found myself on the verge of a precipice, deeper than any I had before seen. At the bottom was a pool, and I should think it was a thousand feet from my station to the water. I rolled a stone down the nearly perpendicular side: it dashed into a hundred pieces, and was several seconds before it splashed into the water. A gust of wind now startled me, and almost made my blood chilly with horror, for it came with force nearly sufficient to send me headlong down the precipice. Soon after, I was completely wrapped in light clouds; this was enough to strike one with terror. After a few seconds, these clouds cleared away, and scudded with the wind along the hollows and sides of the mountain, the intervening rocks receiving a yellow tinge from the reflection of the light of the sun through the mist. Dusky intervening clouds passed on with considerable velocity, which rendered the scene as wild as imagination could paint; and various other tints and shades were thrown on the hollows and mountain sides by different reflections of the light through the more or less dense mediums. My station commanded the whole dome of the sky, and presented me with majestic scenery. The prospects below, which I had before considered separately as grand scenes, were now only miniature parts in the immense landscape. There were numerous beauties in this vast expansive scene, but there were wanting woods, hedgerows, and scattered trees to soften the prevailing black and dreary features. There was a wonderful variety of mountains, receding in succession to the horizon, which appeared immensely distant; and the eye was severely tasked to trace out where in the distance was the real boundary of the scene. Though full of sublimity, the scene wanted the charms that can only be given by cultivation, or by a rich wild vegetation, both of which were absent from this vast inhospitable scene. But what about alpine plants? some will say, was there nothing to admire besides the distant views? no plants—nothing but barren rock? In truth, I found plenty to admire and to study, and never saw a place but there was something in the way of vegetation to beautify it. What appears to be nothing but desolation and death is the theatre of a now world in miniature. Every created thing serves for the good of the whole, and so I found on the rocky point of this lofty mountain Nature busy making one plant take advantage of the protection of another, and even turning to use the decaying parts of every vegetable and animal production. The rock was tinged with lichens, and spotted with their coloured fronds: the calcareous lichen, consisting of a white crust with black tubercles; the crab's-eye lichen, white; the tartarous lichen, yellow and white; the purple lichen, with a leaf-like form, very much lobed; and many others—all pretty and interesting, although so small. In places where the lichens had decayed, mosses had taken their places. The seeds had no doubt been driven thither by the wind, and had generated in this meagre soil.

In the course of time they had grown and produced their green tufts, and these in their turn had decayed, and other plants had taken their places. I could see the evidences of these successions and mutations in many a mixture of dead and living forms. Here I found the saxifrages next in rotation, such as *S. stellaris*, *S. nivalis*, *S. oppositifolia*, *S. hypnoides*, *S. palmata*, *S. caspitosa*, and a few others of less note. *Ericas* and other small plants come next. The Sphagnum moss grows at the bottom, and rots rapidly; thus a layer of earth is formed, into which the larger plants send their searching roots. Such is the progress of Nature—every death is the beginning of a new life. Constantly conducive to the general good are her operations. This is the process which Nature employs to cover the mountain with soil, and fit it for the husbandman, who converts the bogs and shattered rocks into fertile fields and rich meadows. But the use of lichens and mosses is greater still. They have a property to attract moisture; they draw towards them the clouds, and hence the tops of mountains are almost constantly involved in vapour. As they cannot retain all the moisture that distils upon their summits, much of it sinks into the clefts and crevices, whence it proceeds from all sides to the lower levels, and at last appears in the form of springs. Many small springs unite and form a rivulet, which in its progress swells to the size of a large stream. Then to the apparently insignificant mosses we are indebted almost entirely for the mightiest rivers; and to them, moreover, do we owe the desiccation of extensive swamps, and the fertility of soils which originally were most unfruitful. And here even on the top of a desert mountain the lover of the intricate and beautiful amongst Nature's handiworks may revel in the purest of all pleasures—that of reflection on the singular economy of the vegetable kingdom, and the vastness of that power which keeps all the laws of the material world in motion. It is not the mere individual objects, but the knowledge of circumstances and accompaniments, and the connexions that subsist between them, that most profitably engage our thoughts. We must look upon Nature's productions, in all their variety, as one great whole; we shall find that all parts harmonize, and are mutually and reciprocally useful and necessary to each other. The foundation of utility as a source of happiness consists in people seeing and knowing that which is around them, and which they may examine any day or every day, without cost and without trouble, and which will prove to them a perpetual source of enjoyment.

I continued my route to the left, over a series of points and crags, stopping at different times to enjoy the prospects and various plants that presented themselves, and soon after made my way to the hollow. There I turned round to look at the station I had left, and from below it appeared an immense height. I came to several little rivulets, in many places thrown over low rocks, and forming small but sometimes elegant cascades. I followed the course of the stream, looking in every direction for the great fall, as I was told it was conspicuous a long way off, but all to no purpose. I listened in hope of hearing its sounds, but it was still in vain, for I was not in the right road, as I afterwards found to be the case. I wandered along, hoping to see a human being or a house—two very scarce things, for I had not seen either since my start. At last I espied a cottage; it seemed but the habitation of misery from the exterior; the construction was of shaly stones, with which the country abounds, and just sufficient mortar to cement them together, and keep out the mountain blasts. A low roofing of straw; a chimney of the same, bandaged together with hay rope; the window small, consisting of boards, and in which rags had taken the place of glass. When I went to the door, I was met by two dogs and an old sow; these were the only occupants I could see. The door seemed to answer the purpose of a chimney as well, for I found the smoke coming that way; and the light, I suppose, when this door was shut, came down the chimney, for it was impossible it could come through the window. Of furniture there was everything that could be mentioned; every part of the wall was hung with something, and so was the ceiling, the wooden beams of which had the appearance of a little museum. When I knocked, the dogs barked; at last a female put her head out of a hole in the roof, or window, and after a great deal of trouble, and many signs, as she could not speak nor understand one word of English, I found out the way to the waterfall. I had to cross another high bill. Having gained the summit, the views were equally extensive and wild as those I had seen already. I cannot describe the sublime forms the mountains exhibited—rolling, as it were, over each other, varying in size and form until they insensibly lost themselves in the horizon. From hence may be seen both Cader Idris and Snowdon, the two monarchs of the British Alps; and here I caught the first sight of the cataract rolling down the side of the opposite mountain. The fall is terribly grand; it is 220 feet high, and for nearly two-thirds of this height the water is thrown down the flat face of a black naked rock. From thence it rages through a natural arch, and betwixt two prominent rocks passes into a small basin at its feet. Here the stream is confined within a rocky chasm, which offers so many obstacles to the progress of its impetuous course that it is everywhere covered with angry foam. The whole scene is nearly destitute of wood, but it has so much simple grandeur that many trees would injure rather than heighten the general effect. Sir Watkin Wynne has erected a neat cottage at the foot of the rock for the accommodation of visitors, which is very convenient to those who bring refreshments with them. On my return from the cataract, the people put me in the right road for Cynwyd, and told me to make all speed, as darkness would overtake me before I got off the mountains, as it was half-past three o'clock. I paid little regard to the advice, and I had occasion to repeat it, for in a very short time the wind began to roar among the rocks, and I could see narrow skirts of clouds brushing the tops of the mountains before me. I could perceive that they became more condensed and black, till at last the mountains and the clouds became one solid black mass. This I had to make head against, and pass into or through, if I could find my way. The fiery rays of the sun at the misty extremity gave to it an awful appearance. With the velocity with which the lower clouds were moved, the sides of the mountain full half-way down had the terrible aspect of a volcano; the clouds looked like volumes of smoke as they were driven by the wind. It was too plain I had tarried too long, and must make my way with all possible expedition. The clouds increased rapidly, and appeared to block up the mouth of my retreat. Still I hurried on till I came to the clouds, for they had gathered before me. The wind seemed to be blowing a hurricane. I paused for a moment, and considered whether or not I should go or return to the cottage at the waterfall. I was resolved to proceed, and I entered the clouds and made the utmost exertion to reach the top. This I did, but not before I had several ups and downs. When I got to the summit, the wind blew a

hurricane, the clouds beat like wet sails upon my head, and I had to exercise great care, clinging to the projecting rocks, crawling on all fours, and feeling my way with a stick. This stick I found a most useful companion, and without it I should have had to stay on the top all night, exposed to cold and tempest, without any hopes of making my distress known. I hurried on. My downward course was pretty good. I was anxious to get out of the darkness; but total darkness had set in amongst the hollows as well as on the hills, and I had yet three miles of swampy moors to traverse. The prospect became somewhat alarming, for I knew how treacherous some places were, and what awild, dreary, and comfortless journey it was in daylight. The lumps of white rock that were here and there peeping out of the black mould helped to darken and bewilder me, till I did not know which way to steer. I did not now whether I was going backwards or forwards. I kept tumbling about till I came to a rugged glen amongst the rocky banks, at the bottom of which runs a rapid torrent. The water was more plainly heard than seen in this dark chasm: it was full of horrors. The only course left me was to follow the water. This I did for a very short distance with the most painful efforts, and repeated struggles with bogs and rocks. Finding that danger was every step increasing, I was obliged to wait till the moon rose. I mounted a rocky pinnacle, and there I sat in this distressing situation, better to be conceived than described. I had not to wait long before the moon arose, and shone very brightly; but it lasted only for a short time, and seemed only to tantalize my hopes, for as I proceeded it became eclipsed by the mountain. I stopped, anxiously watching it moving, hoping it might soon again light my path. I had not to watch in vain; and after a troublesome and hazardous journey over rocks, crags, and through bogs, I arrived at Bryn Hyfryd, the place of my abode for the night; and from the countenance of the mistress of the house on my appearance, I suspect the family had believed that I should not again return.

N. COLE.

THE APPLICATION OF MANURES.

Lecture by PROFESSOR VOLCKER, before the London Farmers' Club.

It is no part of my duty to-night to have to direct your attention to an agricultural discovery with which I may be supposed to be more familiar than others engaged in the practical pursuits of life. Agricultural novelties, emanating from scientific men, I am sorry to say, seldom are such as to inspire good farmers with much confidence in the wisdom, judgment, and sound business character of their originators. If, however, the subject on the discussion card has not the doubtful merit of an agricultural novelty, nor the charm of an ingenious invention, I believe it has the advantage of giving gentlemen a good opportunity of discussing the pros and contras of certain prevailing practices of applying natural and artificial manures to the land, or of reconciling many apparent contradictions in the actual practice of different farmers. In inviting discussion to-night, I hope those taking part in it will not be satisfied merely stating the results of their actual experience, but that they will also point out the reason why they prefer one practice to another, and why the plan which is generally adopted by intelligent farmers is not resorted to in their case. Our practice, as regards the best time and most approved mode of restoring fertility to the land by means of manures, evidently must greatly be modified, according to the chemical composition and properties of the fertilizers which we wish to employ, the chemical and physical properties of the soil, and the requirements of the plants which we wish to cultivate. In order to be of any practical use, agricultural matters should be treated rather in detail than in a general way. It may be very useful to a country gentleman to have some general ideas of farming; but I very much question whether such ideas alone would be of much use to the rent-paying farmer, who, amongst other particulars, must know exactly how and when to apply the various fertilizers which practice has pointed out to him as the most profitable for raising good crops of wheat, barley, or turnips. I therefore propose to treat my subject less from a general or theoretical point of view, than to enter somewhat into details respecting the most approved modes and periods of applying manures to the land. In the first place, I shall have to speak of the circumstances which ought to regulate the manner and the time in which farm-yard manure is most usefully employed, and then it will devolve upon me to offer similar remarks on guano, bones, superphosphate, nitrate of soda, and a few other artificial manures.

FARM MANURE.

The principal questions on the mode in which farm-yard manure should be used, and the best time at which it should be incorporated with the soil, appear to be the following: Should it be used long and fresh? or short and rotten? Should it be carted into the field and ploughed in at once? or may it not be spread on the land, and ploughed in at the convenience of the farmer, without deterioration of its qualities? Is it desirable to distribute manure in a field in small heaps, and to leave it in that state for days or weeks? or should the manure be spread at once, and may it be left exposed to the air in such a state for some time, in case heavy rains should set in, and the wet condition of the land render the ploughing-in of the manure undesirable? What is the best time of the year for carting manure on the land? Should this be done in autumn or in spring? or may it be done at any convenient time, no matter what is the period of the year? To what crops of a rotation should farm-yard manure be used, where a sufficient quantity is not produced for meeting the requirements of the crops intended to be grown, and the deficiency has to be eked out by the employment of artificial manures? On all these questions great variety of opinions prevail. Allow me to state at once that I have always been an advocate for putting the manure on the land as soon as possible after it is produced, and that I believe autumn manuring, as a general rule, will be found more advantageous than spring manuring. It is not enough, however, merely to give expression to these convictions, for you will naturally expect me to support them by such proofs as will carry with them also conviction to your minds. In attempting to do this, I do not wish to weary you with chemical details; but it will be necessary, for a clear understanding of the subject, that I should speak as briefly as possible of the composition of fresh farm-yard manure, and the changes which it undergoes in keeping, or by exposure to the air. Chemically considered, farm-yard manure has to be regarded as a universal and perfect manure. It is a universal manure, because it contains all the constituents which our cultivated crops require to come to perfection,

and it is suited to almost every description of agricultural produce. As far as the inorganic fertilizing substances are concerned, we find in farm-yard manure potash, lime, magnesia, oxide of iron, silica, phosphoric acid, sulphuric acid, hydrochloric acid, and carbonic acid; in short, all the materials, not one excepted, that are found in the ashes of agricultural crops. Of organic fertilizing matters we find in farm-yard manure some which are readily soluble in water, and contain a large proportion of nitrogen; and others insoluble in water, and containing, comparatively speaking, only little nitrogen. The nitrogenous matters are principally present in the droppings and urine of animals, and yield ammonia on decomposition. The straw or litter in the manure hardly contains any nitrogen, and on decomposition produces brown vegetable organic acids, which pass under the name of humic acids. These organic acids—which, as we have just seen, are produced simultaneously from straw, with the ammonia arising from the putrefaction of excrementitious matters—have a great affinity for ammonia, in consequence of which they fix it as readily as sulphuric or any other mineral acid. For this reason I may observe, in passing, that chemical fixers of ammonia are perfectly unnecessary in farm-yard manure in which a due proportion of litter is used. Farm-yard manure is a perfect manure, because experience as well as chemical analysis shows that the fertilizing elements are present in it in states of combination which seem to be specially favourable to the luxuriant growth of plants. And I would direct special attention to the fact that fresh farm-yard manure, although it has a strong smell, practically speaking contains no volatile or free ammonia; and I may add that I have also found none worth mentioning in perfectly rotten dung; and of course, where no free ammonia exists, chemical fixers of this substance are quite out of place. It is true ammonia is produced abundantly on the decomposition of the urine and solid excrements of animals; but it is equally true that during their decomposition peculiar organic acids are formed in the rotten straw, which effectually bind the ammonia and prevent its escape into the air. We have thus good grounds for maintaining that artificial fixers of ammonia are neither required for fresh nor rotten dung, and also for asserting that both fresh and rotten dung may be freely exposed to the air without loss in ammonia, for the former contains hardly any ammonia in any form, and the latter contains it in the form of ammoniacal and volatile salts. Farm-yard manure, as is well known, is subject to the process of spontaneous decomposition, which generally is called fermentation, but more appropriately putrefaction. The nature of this process consists in the gradual alteration of the original organic matters, and in the formation of new compounds. All organic matters, separated from the living organism, are affected by putrefaction, some more readily, others more slowly. These organic matters, which, like straw, contain but little nitrogen, on exposure to the air and moisture at a somewhat elevated temperature, decompose spontaneously and slowly, without disengaging any noxious smells. On the other hand, the droppings of animals, and especially their urine, which is rich in nitrogenous compounds, rapidly enter into decomposition, producing disagreeable-smelling gases. In a mixture of nitrogenous and non-nitrogenous matters the former are always first affected by putrefaction; the putrefying nitrogenous matter then acts as a ferment on the other organic substances, which by themselves would resist the process of spontaneous decomposition much longer. The disagreeable-smelling gases which are produced during putrefaction arise from the sulphur and phosphorus of the nitrogenous compounds present in dung. A considerable proportion of this sulphur and of the phosphorus combines with hydrogen, and form sulphuretted and phosphoretted hydrogen—two extremely nauseous gases—which both escape from fermenting dung-heaps. The relative proportions of inorganic to the organic matters in well-rotten dung is much greater than in fresh. This increase in mineral matters can have only been produced at the expense of organic substances, the quantity of which during the process of fermentation must decrease in a corresponding degree. Thus, whilst I found in fresh dung, dried at 212° Fahrenheit, organic matter 83.48, inorganic substances 16.52 per cent.—rotten dung shows in 100 parts, organic matters 68.24, mineral or inorganic matters 31.76. It is clear, therefore, that during the fermentation of dung, much of the organic substances must become changed into compounds which are readily soluble in water, and easily washed out by heavy rains, or into gaseous products which are readily volatilized. In point of fact, both volatile gases and readily soluble organic and inorganic compounds are formed. By far the largest proportion of the gases which escape into the air consists of carbonic acid gas, oxide of carbon, and light carburetted hydrogen, or marsh gas; and it is worthy of special notice that no appreciable amount of ammonia is dissipated. Now this is not a mere assumption, but a fact which can be readily ascertained by any one who has the skill of discerning the amount of ammonia with accuracy. The practical result of the changes which take place in fermenting dung is, that fresh manure, in ripening, becomes more concentrated, richer in nitrogen, weight for weight, more soluble, and consequently more easily available to plants, and more energetic in its action.

The per-centage composition of fresh and rotten manure, however, does not throw much light on the question whether a dung derives any loss in ammonia during ripening, and to what causes are really due its deterioration by exposure to wind and weather. But if a given weight of manure is put up in a heap, and its composition ascertained from time to time, and its loss in weight is simultaneously determined, then it is clear it is possible to ascertain whether the rotten dung which is produced from a given weight of fresh contains the same, or less, nitrogen than was originally present; and by exposing the rotten dung afterwards to heavy rains, we can also determine the reason why it deteriorates so rapidly under their influence. This I have done a great many years ago. Two cart-loads of fresh farm-yard manure were placed in a heap set against a stone wall, but otherwise exposed to the influence of the weather.

Without entering much into particulars, I may observe that, in the first experimental period, the fermentation of the dung proceeded with rapidity, but was unattended with any material loss of ammonia, nor, indeed, any appreciable amount of the more intrinsically valuable constituents of dung. At the end of April (as will be seen), the whole heap contained almost precisely the same amount of nitrogen which it contained when put up fresh in the preceding November. During that period little rain fell, and this never in large quantities at a time; whilst in the interval of April and August rain was more abundant, and fell several times in continuous heavy showers. In consequence of this, soluble matters in the heap were washed out, and with them a considerable portion of available nitrogen and the more valuable mineral constituents of dung were wasted. The general

conclusion which may be drawn from these experiments is evidently that manure loses no valuable fertilizing matters by simple exposure to dry air, and, I may add, nor even by exposure to a broiling sun, but that it is rapidly deteriorated by rain. Now it is upon these undeniable facts that I found an argument for carting the manure on the land as soon as it can be done conveniently. Once placed there, neither sun nor wind will hurt it, I believe, in the slightest degree; and when rain falls, the soluble matters will be washed into the soil, where they are wanted, and stored up there for the use of plants; for all soils—some in smaller, others in larger degree—as is well known, possess the power of absorbing and retaining, in a comparatively speaking insoluble condition, the more valuable soluble fertilizing constituents of dung. If the manure is carted on the field during the autumn or winter, and spread at once, it will, even when perfectly fresh, become sufficiently decomposed by the time it is required by the spring crops, and the unnecessary expense of putting up manure in heaps, and turning them over once or twice, and the loss attending such turning, may be entirely avoided; and this may be done at a time when the horses have little or nothing to do, and the fields are not injured by the horses' hoofs. I advocate autumn and winter manuring, because autumn and winter, generally speaking, are the most convenient periods for carting manure. There is, however, not the slightest reason why this may not be done at any convenient time throughout the year; for, as I have said before, not even a broiling sun dissipates any valuable fertilizing matter from manure.

Many persons, if I am not mistaken, entertain rather erroneous views with respect to the desirability of ploughing in the manure directly it is carted on the field. I have of course no fault to find with this, if their anxiety to plough in the manure directly arises from the wish that whatever can be done at once should be done without delay; but if this is due to the fear that manure, if not ploughed in directly, will lose in fertilizing quality, I cannot share their anxiety; and go so far as to say that often it would be much better to leave the manure freely exposed on the land in wet weather than to plough it in, and make a mess on the land when horses and men ought to be kept from it. Others take a middle course, and distribute the manure in small heaps, and leave it in this state until a convenient time occurs for spreading and ploughing it in. Now this, I do not hesitate saying, is an objectionable practice; for if heavy rain should fall continuously for a number of days, these small heaps will be washed out, at least partially, in consequence of which the portions of the field where the heaps were placed will receive too much of the soluble and most fertilizing matters, and the crops there become too rank, and the produce on the field will ripen unequally. I have observed over and over again the injury which may be caused by the objectionable practice of distributing manure in small heaps on the land, and leaving them for weeks together before spreading the manure. I would therefore advise the manure to be carted on the field whenever convenient, to spread it directly, and not to trouble about ploughing it in at once if rain should set in, even if the wet state of the land should render it advisable to keep horses and men from it for weeks or months. The views which I have advanced I am aware are not accepted as correct by some agricultural authorities. Thus, for instance, I find in an article on the farming of Leicestershire, in the last volume of the *Journal of the Royal Agricultural Society*, the following passage: "Lord Berners puts great stress on covering up the manure when laid in small heaps on the land, and cites an instance where the labourers were overtaken by a thunder-storm while manuring for roots, the ridges being opened and the dung carted on and laid in small heaps. A portion was covered with soil previous to the storm, and the remainder left for a few days exposed, the manure and treatment being in every other respect the same, but the difference in the crops was most astonishing. Where the manure was covered the produce was nearly double. Nor did the difference end with the root crops, for the barley succeeding was also very much better on the covered manure. This scarcely accords with the scientific conclusions of Professor Voelcker, who does not anticipate harm from exposing manure if spread on the ground. Lord Berners, however, is far too practical and acute an observer to allow us to have the slightest doubt as to his accuracy, and this is one of the instances where the teachings of science and the facts of practice cannot be easily reconciled." In explanation of this passage I would observe that I have not the slightest doubt about the accuracy of Lord Berners' observation; but that I cannot recognise in it either an instance which shows that the teachings of science and the facts of practice cannot be easily reconciled, nor a proof that manure sustains any loss by evaporation. Incidentally, I may also observe that I never taught to leave manure in small heaps in a field, but that it should be spread out at once. The real cause why, no doubt, Lord Berners got a bad mangold and barley crop on that portion of the field where the labourers were overtaken by a thunder-storm appears to me a very simple one. The field was a heavy clay land, and therefore it is not at all surprising that where the manure was got on the land and ploughed in before the rain interfered with the operation, the mangold and succeeding barley were good, and these crops turned out bad on the other portion of the field simply because the land was messed about after the thunder-rain, and not because the manure lost in quality by exposure to the air. At all events it is a fact well known to clay-farmers that on stiff laud a better crop is often obtained without any manure when worked dry than with manure when worked wet. With regard to the crops to which farm-yard manure is best applied, I would observe that time does not permit me to dwell on particulars; I therefore will only notice that on farms on which farm-yard manure is scarce, and recourse must be had to artificials, the most economical plan to use the manure appears to be to grow the root crops mainly with artificial manures, and to spread the yard dung on the seeds or clover-lay.

ARTIFICIAL MANURES.

I must now hasten on to offer very briefly some observations relating to the manner in which some of the more important artificial manures should be used on the farm. All concentrated manures, such as guano, nitrate of soda, or superphosphate, should always be mixed with some diluent or other, and applied in a finely divided state. Artificial manures may be conveniently divided into nitrogenous and phosphatic manures. The former, as is well known, are especially useful for cereals and grass crops, and the latter for root crops. Concentrated nitrogenous manures, such as guano, nitrate of soda, sulphate of ammonia, &c., I am of opinion should never be ploughed in deep, or applied with the drill, but be spread, properly diluted with dry and fine soil or burnt clay, vegetable ashes, or sifted coal ashes, by hand, or better by the broadcast distributor, and

harrowed in very lightly. Superphosphate and bone manures, on the other hand, should be drilled in at the time of sowing the seed. When the land is very light, or out of condition, so that rather a heavy dose of manure is required, it seems to me advisable to sow a portion broadcast, and to drill in the remainder of the manure with the seed. The state of preparation in which artificial manures are sold by dealers often is not what it ought to be, and particular care should be exercised by the farmer not to use any which are wet, lumpy, or otherwise badly prepared. This remark applies specially to bone-superphosphate. Even some of the most respectable manufacturers, I find, sell badly-prepared bone manures—that is to say, manures in which pieces of bone an inch long and longer, and scarcely acted upon by acid, are plainly visible. This arises from a desire to convey the impression that the manure is made from bone; frequently, however, so-called bone-superphosphates are in reality made from mineral phosphate and acid, to which a few plums of bone have been added. But even should the manure be made entirely from bone, it would be far better if it were thoroughly disintegrated, and sold in a dry pulverulent state. As regards the quantity of superphosphate useful for root crops, I may mention that sometimes mistakes are made by employing too much. As a general rule, 2½ to 3 cwt. of a really well-made and good superphosphate appears to me an amply sufficient quantity for raising a good crop of turnips or swedes on land in a fair agricultural condition, provided the superphosphate is properly diluted with ashes or dry soil before drilling, or applied with the liquid-manure drill. Considering the great advantage of distributing much more uniformly turnip manures by means of the liquid-manure drill than by the dry drill, I am surprised that the former implement has not superseded to a greater extent the employment of the latter. There can be little doubt that where water is at hand, the application of superphosphate by means of the liquid manure would effect a great saving in the purchased manure, for we possess trustworthy experiments which show that half the usual quantity of superphosphate gave as large a crop of roots as double the quantity applied with the dry drill.

BONES.

Bones in the shape of ¼-inch and even ½-inch pieces are still used by some farmers. I do not think this is the most profitable plan of applying this important fertilizer to the land. As long as bone-dust was comparatively cheap, and prepared bone-manure dear, the practice of using bones in a raw condition was perfectly defensible; but at the present time the altered circumstances of the manure trade will have the effect of superseding more and more completely the use of ¼ or ½-inch bones. Even for permanent pasture, I believe bones partially dissolved by sulphuric acid will be found more profitable than raw bone-dust. It is true the latter lasts longer than the former; but it should be borne in mind that the purpose for which manure is put on the land is not that it should remain there, but that it should produce heavy crops. Now bone-dust requires a season or two before its action becomes manifest in the increased produce, and all the while the capital invested in the purchase of the bones remains on the land without bearing much interest, which surely cannot be an advantage. "Quick returns and small profits" should be the motto of the enlightened agriculturist, if he wishes to make the most of purchased manures. The profits of farming, I believe, in comparison with those realised in other pursuits of life, are, and probably always will be, small; hence the greater the necessity appears to be to secure quick returns, and not to lock up capital useless in the soil. I would therefore suggest the addition of about 20 or 25 per cent. of sulphuric acid, which will make a portion of the bone-dust soluble, and directly available for the use of plants. The addition of acid to bone-dust, moreover, in localities where crows abound, effectually prevents the depredations of these feathery marauders, who, it is well known, will carry off a good many bits of bone-dust from recently boned pastures.

NITRATE OF SODA.

Nitrate of soda is usefully mixed with about double its weight of common salt before sowing; 1½ cwt. to 3 cwt. of salt is a fair top-dressing for wheat or barley. Top-dressings with nitrate of soda should never be used in winter, but delayed till about the beginning or middle of March. The precise time when nitrate of soda should be put on the land depends on the more or less advanced state of the season, and the proper time of using this top-dressing I found, by many years' actual experience in the field, is the period when the young wheat crop is just beginning to make its first perceptible start in spring. I have used nitrate of soda as late as the middle of April with advantage, and in other years as early as the middle of February with equally good effects. If there is a fair prospect of March being a moderately dry month, I should not hesitate to top-dress with nitrate of soda as early as the end of February; but should the weather at that time and in March be very wet, I would delay the application of nitrate of soda till the beginning or even middle of April. There are two good reasons why nitrate of soda should be applied to the land in spring, and not during the winter months. First, experience has shown the period pointed out by me to be the best; secondly, it is well known that no soil, whatever its composition may be, has the power of absorbing and retaining nitrates; and these highly soluble salts, therefore, are quickly washed away by the rain into the subsoil, where they are not wanted, if they are applied to the land during the winter or early part of spring; and hence it is only reasonable to delay top-dressings with nitrate of soda until the time when the wheat begins to make its first perceptible spring growth. It is well to bear in mind that soils do not possess the property of fixing nitrates. Unlike salts of ammonia, nitrates pass unchanged through the soil into the drains, and are lost to vegetation in a great measure if they are applied to the land in autumn or winter.

AMMONIACAL MANURES.

such as sulphate of ammonia and guano, on the other hand, are best used in autumn or during winter, and not too late in spring. Even on light land it is not desirable to apply guano too late in the season for corn crops. Autumn dressings with guano generally produce more healthy and equal crops than when manured in spring; and as all soils without exception possess the power of eliminating ammonia from soluble salts, guano, sulphate of ammonia, and other ammoniacal manures, may be applied during the winter without risk of losing valuable fertilizing matters.

In conclusion, allow me to throw out a few hints as regards the mode in which guano should be applied to the land. Much more care should be taken than is bestowed upon it to apply it in a good mechanical condition. Guano should never be sown without having been first sifted, and any hard lumps in it reduced to powder. It is a good plan, before sowing, to mix the sifted guano with about an equal weight of salt and double its weight of dry soil or ashes. Salt is a useful distributing agent of the fertilizing constituents of guano in the soil, and moreover prevents the dusting and loss of finer particles of guano during sowing in the field. The mechanical preparation of guano is not quite so easy an operation as some imagine; and this, I believe, is the reason why very few farmers perform it properly. Allow me briefly to describe a plan which I have found to answer well in preparing guano for use. First sift off all the fine guano dust. Then mix the hard lumps left in the sieve with about twice their bulk of sharp sand. Spread the mixture on an even floor, and pass a heavy garden roller over it, or beat down the lumps with a wooden mallet. (The admixture of sand prevents the caking of the guano, and greatly facilitates its reduction to fine powder.) After the whole has gone through the sieve, add salt in the proportion of two parts, by weight, to one of guano. The moisture imparted to the guano by the salt prevents the dusting, which is a great inconvenience in sowing by hand. Salt, in conjunction with guano, moreover, has a specific action on vegetation, which is specially beneficial to corn crops on light soils. I cannot too strongly impress you neither to spare trouble nor expense in preparing guano properly before sowing it: 10s., or 15s., or even £1 per ton will be well laid out, should the labour of preparing it in the way suggested by me cost as much. Peruvian guano contains no more than three-fourths to one and a half per cent. of free ammonia; and hence there is no necessity of adding sulphuric acid to it, with a view of fixing the ammonia. Nevertheless, the addition of sulphuric acid to guano can be strongly recommended, for the reason that it greatly increases the chemical efficacy which this manure is capable of producing in the field. As little as 10 or 15 per cent. of sulphuric acid, added to guano, I find, has an extraordinary effect upon its composition. Sulphated Peruvian guano, on account of the large amount of soluble phosphate which it contains, is certainly more efficacious than guano in its natural condition, especially for root crops. However, the mixing of guano and oil of vitriol, if I am not mistaken, is not a pleasant operation for the farmer, and I therefore do not advise you to attempt it; but if you will prepare your guano mechanically, in the way described just now, and then mix it with a good dry coprolite superphosphate, rich in soluble phosphate, you will secure all the chemical benefit which sulphuric acid itself produces on guano much more conveniently, and thus be able to prepare yourself a really good prepared guano more economically than you can buy chemically prepared guano. For root-crops, one of guano and three of superphosphate made from coprolites, and containing, as it should do, not less than 20 per cent. of soluble phosphates, is an excellent mixture, and a fair dose per acre. For cereals, the proportions of guano and superphosphate should be reversed—that is to say, one of phosphate and three of guano should be employed.

NOTE ON THE CULTIVATION OF AMHERSTIA NOBILIS.

By Mr. TAPLIN, Gardener to His Grace the Duke of Devonshire at Chatsworth.

(From the Journal of the Royal Horticultural Society.)

The age of the plant is probably about twenty-five years; the height 5 feet, the circumference 45 feet. It is planted out in a house specially built for it, in a bed of soil about 6 feet square and 3 feet deep, raised above the level of the surrounding path. The soil is warmed to a temperature of about 85° by pipes underneath.

The soil is good open loam and sand, to allow free passage for water, of which it requires a large quantity during the growing season, both on the surface, and also poured down a perpendicular opening to the heating pipes below, so as to give moisture with bottom-heat. There is sufficient piping to keep the top-heat at 70° even in severe weather. The following is the mode of treatment.

When the plant has flowered, a portion of the old soil is removed from the surface without disturbing the roots, and some nice fresh soil added; it will soon commence growing, when it must be kept shaded from the bright sun; for the young growth especially is very impatient of the sun's rays. I keep the plant sprinkled twice each day, and evaporating pans constantly full of water. The plant generally makes two growths in the summer. The growing temperature is 75° at night, and from 85° to 100° by day.

In the autumn, when the wood begins to ripen, I give less shade, and reduce the supply of water for about three months, but do not allow it to be very dry, and keep some of the evaporating troughs full of water during the winter.

Winter temperature 70° to 75°. In January I give more water, and the plant will begin to show flower by the end of the month, the flowers pushing out very rapidly, and continuing to open for five or six weeks.

There have been this year fifty-five racemes of bloom open, and there are three more to open, in all fifty-eight, with from ten to sixteen flowers on each raceme. The greatest number of racemes with flowers open at one time was about twenty.

FIRST PINE-APPLES IN ENGLAND.—When Oliver Cromwell ruled in these realms, a present of pine-apples was one of the things which fell to his lot, and this was probably the first introduction of the fruit into England, although it was known on the Continent four years previously. Four years afterwards, and Evelyn writes of its appearance on the royal table. But the fruit, however much it may have been extolled, is not the only good product of this plant. From the leaves thereof is procured a fibrous material known and appreciated by the barbarous hordes of Africa and the semi-civilised Malays. The celebrated pine-apple cloth of the Philippines, resembling the finest muslin, is woven with the delicate fibres of the uncultivated pine-apple plant. This muslin is embroidered by the nuns of the convents of Manila with excellent skill and taste, so that the "Pina" muslin of the Philippines has become a celebrated article of manufacture. Mr. Bennett has observed in his "Wanderings" that one of the coarser fibres may be subdivided into filaments of such fineness as to be barely perceptible, and yet sufficiently strong for textile purposes.—*Hardwicke's Science Gossip.*

THE CYCAS AND ITS ALLIES.

It is only the possessor of a large conservatory who can hope to do justice to the *Cycas*, the *Zamia*, the *Dion*, and other members of the remarkable family of *Cycadaceæ*. But where there is sufficient room and warmth, and plants of fine form are valued, a certain few of these are indispensable to give richness to a scene which must have more or less of a tropical aspect. They are among the most wonderful of all the plants in cultivation, and they must always be costly, for we cannot chop them up and multiply them like soft-wooded plants, nor can we force them into rapid growth and make specimens quickly. Nature is our mistress here; Art is a trifle only in comparison of the fixed habit and non-compliant temper of these noble members of the vegetable kingdom. I can never look on a grand specimen of any one of this tribe without reflecting on the long series of years during which it has grown solely and grandly in its own way, and I have sometimes attempted to arrive at some correct knowledge of the age of a *Cycas* or *Encephalartos*, but I confess with no satisfactory result. They are botanical enigmas.

Australian grass tree (*Xanthorrhæa*) which must have been growing a couple of centuries ere it was torn from its native site in the wilds to adorn a display in this land of wealth and luxury and high taste. The *Cycas* is in another respect a conifer, for the flowers are nearly related thereto, both male and female; in fact, we may call a female inflorescence a cone, and we may find in it naked ovals as in the cone of a pine or fir. Moreover, a section of the wood under the microscope displays a structure close akin to that of coniferous timber. When we see their huge pinnated leaves unfolding from the crown, we are persuaded that they bear relation to the ferns; and the scars left after the leaves have fallen are like those left by the articulated series of ferns upon the woolly or scaly rhizomas. I say these plants are botanical enigmas, and no one who has reflected upon the origin of species can doubt that they have played their part in the modification of less ancient forms of vegetation, but how or when no man can say.

At Kew there is a fine collection of these wonderful plants, and they have good treatment, as is evidenced by their healthy appear-

ENCEPHALARTOS CAPFRIA.

They are living records of a dead past, and connect the present with ages when man trod not the earth, and gigantic forms, animal and vegetable, dwelt amid the steaming atmosphere which marked the last decline of the subterranean fires which have apparently quite gone out. I shall not attempt to descant upon the part the *Cycas* played in the vegetation of far-off geological ages, but I must at least reflect upon their antiquity when I compare their forms and physiology with their nearest congeners of the vegetable kingdom. What is a *Cycas*? It is in one respect a palm; the leaves all proceed from the summit, the stems are simple and cylindrical, and though we are accustomed to see stems only a foot or so high, there are some that attain a height of thirty to forty feet, and it would perplex us to say how many years must pass ere such a growth is attained. A friend has just shown me a nice plant of *Todea pellucida* with a stem rather more than a foot high, and has asked me what may be its age. He is astonished to hear me say that it must be over a hundred years of age. I remember Mr. Williams presented to a flower show, which was one of the first I attended after I landed on these shores, a plant of the

ance. I have not seen amongst any of the best collections of plants on the Continent, a greater variety or finer specimens than those at Kew, but there does not exist in cultivation specimens which represent the actual magnitude or the picturesqueness of these plants, for it is impossible to import gigantic specimens, and to keep them would be even more difficult than to obtain them. In their native localities they are in most cases important because of their real usefulness. They furnish an abundance of wholesome food; indeed, the Japanese and Surinam name for our well-known *Cycas revoluta* is a term meaning "Sago palm," though the true sago palm (of commerce) is a palm, and not a cycad. It is from the pith of the stem that the sago is prepared. In the Moluccas this sago is largely used as food. From *C. circinalis* also sago is prepared. From the *Zamia* also, in the Bahamas and West Indian Islands, they prepare an excellent arrowroot from the starch which is obtained from the stems of *Zamia integrifolia*; and in Kafir-land, a bread or eatable paste is prepared from the starch of *Encephalartos capfria*, the native name of which plant is "Caffre-bread."

CYCAS REVOLUTA.—This grand plant is one of the requisites of a

good collection, if grandeur of form is required; and I do not wonder that those who have fine plants prize them, and believe that as wealth and refinement increase, there will be more and more demand for specimens. In my first visit to Mr. B. S. Williams's interesting nursery, I was struck with the fine condition of numerous grand examples of this and other cycads (some of the specimens are unique). But those we see, though gigantic sometimes as compared with the common inhabitants of our plant houses, are pigmies as compared with the monsters that may be found in some tropical swamps. And I hope the young cultivator who is trying his hand with such plants will remember the word *swamps*, for it is only where water abounds, with great heat, that the finest examples are met with. The greatest examples ever introduced to Europe were those sent to Ghent some ten years ago, the tallest of which measured 9 feet 3 inches high from the ground to the top of the trunk. Mr. Regel has noticed that in Surinam these plants become gigantic when located in marshes, where sometimes they make two distinct growths in the course of a year, owing to the peculiarities of the climate; but in China and Japan, where there is less heat, and when they are located in drier spots, they make but one growth, and this is less luxuriant, though fully as beautiful as that accomplished with the aid of excessive heat and moisture. And I would here make a remark for the cultivators, that according to the original location of the plants is their habit (climatologically considered) for all time to come, so far as human experience can teach us. Those who wish to place this plant in a comparatively cool house—that is to say, to adapt it as nearly as possible to the treatment of a hardy plant—should obtain, if possible, plants from China or Japan, for these are habituated to a lower temperature and less moisture than those which grow in tropical swamps. My meaning in respect of their habit being fixed for all time to come is this; that plants from hot swamps will not submit to cool treatment; they require the treatment of the hottest of the orchids; but those from cooler districts will bear cooler treatment, and to alter their constitution, even by the most careful course of acclimatization, appears to be impossible. If any of your readers have cooled down a hot plant of Cycads so as to bear cool treatment without injury to the specimen, I shall be most glad to hear; and I make no doubt you will be glad also, for it is a matter full of interest. Why, as touching this question, every plant of the well-known *Araucaria imbricata* has a constitution of its own: some of them will bear the extreme cold we know of in Europe; others are killed by a severe winter; and *all* are injured by being placed where a constant sharp wind prevails all winter. The Belgian plants of Cycads *revoluta* that were brought from Surinam have required a greater heat than other specimens of the same plant under the same roof; and probably they will never bear such cool treatment as such as come from cooler climates. Those Belgian plants were found in a marsh which is almost constantly bathed in sunshine; the heat is fervid, the water plenty.

By far the larger proportion of all the plants of this species known are females, and the fruit they produce is infertile. I have seen many examples in a state of fructification. Thunberg and Siebold rarely saw male plants; Mr. Regel never saw a male in Surinam, though the plant is there most abundant in the swamps. A male plant once flowered at St. Petersburg; and I find it on record that in the collection of Miss Neilson, of York, one flowered in the year 1833, and the same plant subsequently flowered in the Sheffield Botanic Garden in 1839. Since then males have flowered in two or three botanic gardens on the Continent; but to this day no one has ever had the opportunity of fertilizing a female flower-head by means of the pollen of the male. To see the female flowers is an interesting spectacle which it has been my lot oftentimes to enjoy. The inflorescence has at first the appearance of a human head covered with auburn hair. Afterwards it is like a coronet, consisting of upwards of a hundred woolly stalks like gaunt birds' claws, which branch into smaller divisions. At the base of these claws is produced in clusters a number of red or rose-coloured fruits, flattened, the size of a plum, all covered with brown pubescence, which comes off at the least touch, and shows the lovely colour of the fruit. There are hundreds of these fruits in the entire collection; my friend, August Wenherdt, told me he counted 1,126 in one that he had the privilege to examine at Berlin. It is possible, and most probable, that neither male nor female plants ever flower till nearly a hundred years of age; it is certain that they may be kept twenty or thirty years in the same house, and not show signs of any fructification. I can say with certainty that fruiting may be induced by starving the plant four or five years; but care must be taken that it does not suffer in health by the process.

To grow this plant well needs a free, sandy, and rich soil, a good moist heat, and plenty of pot-room. When suckers are produced, it is a good thing for the cultivator, as he may then make sure of young plants. Those obtained from comparatively cool and dry parts of the world are to be preferred, though they grow less fast

than such as are obtained from the hottest districts; the cool plants will bear and enjoy all the heat of the stove, but the hot plants will not at all bear cool treatment. *C. angulata* will bear the coolest treatment of all. *C. circinalis* must be kept in the stove, and so must *C. squarrosa*.

ZAMIA, OR ENCEPHALARTOS.—The *E. Caffra* is quite a cool conservatory plant, as might be expected from the country it inhabits. It is of most noble proportions, and grows very slowly. *Zamia angustifolia*, *Z. horrida*, *Z. cycadis*, *Z. lanuginosa*, *Z. latifolia*, *Z. longifolia* (a splendid species), *Z. pumila* (a pretty little species for small houses), *Z. spinosa*, are all such as you call (but not wisely I think) *hardy* greenhouse plants, being natives of South Africa. I could name some more which we have in good collections on the Continent, but I do not think you have all I have already specified, and you beg me so not to make long lists of plants that you say "nobody can obtain." You may grow all these in the stove if you will; the heat will not kill them if with abundance of water in the growing season; in fact, they have a deluge of rain in their own country when the season of growth occurs, and at other times they are parched with heat and smothered with sandy dust. The soil should be rich and sandy. When suckers appear, take care you make of every one a plant.

DION.—I see that in some of your books the noble Dion is described as a palm, but it is in truth one of the Cycads. *D. edulis* is one of the most magnificent plants known to cultivation. The name is a good one, for the scales which compose the cone are two-lobed, and the edible seeds are produced in twos. It is very palm-like, and attains a gigantic size, though the specimens in cultivation are mostly small. This will sometimes produce suckers, but very rarely, unless an operation be performed. I learned that this could be done by a plant that was much injured, so that the crown was cut vertically. Two years afterwards it produced a number of suckers, and the fact was kept secret. If we had the courage to hack a fine plant with a hatchet, I do not doubt that it would pay in the end, but I do not advise it. I am content to record what I have seen. This plant requires to be potted in much the same way as a heath or epacris, the soil to consist of lumpy loam, with plenty of sand and broken bricks, and to have the drainage of the pot or tub very carefully arranged. When growing, it must have plenty of water. It will winter well in a temperature so low as 45° to 50°, though usually kept much warmer. In summer, a good stove heat is necessary.

I here quit this subject, which is after all interesting to only a few amongst the thousands of plant-growers. Still we must consult the interests of the few rather than the many. You see that in Prussia the minority were the active agents in bringing about what the majority now accept as good. So let us hope that while there are so many who have no care for Cycads, the time will come when many will desire to know all about them. Then I think I can write another chapter; but for the time of this I do as you wish; I am brief.

KARL PROSPER.

MY ORCHID HOUSE.—No. X.

THE LYCASTE.

It will not be necessary for me to occupy much space in introducing the Lycaste to the reader's notice, for most people who are in any way acquainted with orchids and orchid growing, know more or less about it, as some of the varieties have been so prominently brought forward within the last few years as "fit and proper" candidates for the cool house. Indeed, with the exception of the *Odontoglossa*, I have no hesitation in saying that some of them, particularly *L. Skinneri* and its varieties, are quite as well, if not better suited for that purpose, than a great many of the different kinds of orchidaceous plants which have been very strongly recommended by the different advocates of the cool treatment system. Whilst I am by no means convinced of the practicability of carrying the cool treatment to the extent which some people suppose to be possible, I am not so thoroughly and effectually prejudiced as to shut my eyes to the fact that some few orchids can not only be grown without much fire-heat, but will certainly do much better in a low temperature. It would be undoubtedly a decided advantage if all could be successfully grown without the assistance of a high temperature, for it would effect a vast saving in both the expense of maintaining it, and the extra time and trouble which is necessary, as compared with the management of a low temperature. I was going to say it would add to the pleasure already derived from them, were that possible, to be able to inspect them when in flower in a temperature congenial to one's feelings, than to what it is in one which I have heard some people compare to a Turkish bath. But it is never necessary for the admirer of the flowers of orchids to suffer parboiling except in rare and peculiar cases, for when in flower the plants of most kinds are much better removed to a cool house; and if carefully managed, and kept dry both at the roots and overhead, the flowers will remain in perfection double the time they would do if left in their growing quarters, and the

plants will not suffer the slightest injury. Therefore the idea of the necessity of people being next to roasted or boiled alive, to be able to see orchids in bloom, is nothing less than a fanciful objection.

A very good temperature to grow the *Lycaste* in, and one that will be very suitable for it, is from 55° to 65° through February and March, which will start them beautifully, and then as the days lengthen and the principal atmospheric warmth is derived from the sun, a rise to 75° or 80° will keep them growing vigorously, and enable them to complete their growth early, so that the young bulbs will be well ripened and able to stand a low temperature of from 45° to 50° through the winter. When the season's growth is about finished, and the plants are gradually declining to rest, they should have all the light they can conveniently be exposed to without the sun actually scorching them. I might mention here that it is very difficult to keep them in a low importance through the winter, unless the young bulbs are thoroughly matured; and as I have mentioned on former occasions, the temperature of this cannot possibly be overrated, and a great deal (if not everything) depends upon this as to whether the plants bloom profusely or not the following season. There will be no difficulty in growing the *Lycaste* in a mixture of equal parts of sphagnum and rough fibry peat, combined with plenty of drainage to allow free egress for the water, which should not be administered in too great abundance even when the plant is in full growth, and not more than is sufficient to keep the bulbs from shrivelling when it is at rest. Some of the varieties have large fleshy bulbs, which are exceedingly liable to decay at the base if kept too wet at any time, particularly through the winter. To guard against this as much as possible, the plants should be potted so that the base of the bulb stands three or four inches above the rim of the pot, varying it according to the size of the plant, the same way as I advised for the *ampliatum* section of the *Oncidium* when treating upon their culture a few weeks back. The *Lycaste* is propagated by division, which is best effected in the spring, after the young growths have pushed about an inch or so in length.

The varieties of the plant we have under consideration are not so very numerous, but all that are in cultivation are well worth growing. Certainly none of them are particularly grand or magnificent, but still very beautiful, and are what we might term a first-rate middle-class orchid. *L. aromatica* blooms in May, with lovely yellow flowers which are most deliciously fragrant. One good-sized plant of this kind is sufficient to perfume a large house. Another good kind is *L. cruenta*, which flowers two months earlier than the preceding, with yellow and crimson flowers. *L. Deppei* is also worth growing; it has a pretty yellow flower, with a brown lip, and is in perfection in June. *L. Laurenceana* is a splendid variety, and should be in every collection. Last, but not least, comes the beautiful *L. Skinneri*, and its two lovely varieties, *albida* and *superba*, which flower in October. GEORGE GORDON.

THE MEXICAN AGAVE.

The American Aloe (*Agave Americana*) is a native chiefly of Mexico, but it is found in other parts of America. The precise date of its introduction into this country is not known, but it is recorded that one flowered in Lameth in 1698. It grew to a height of from 12 to 15 feet, and was considered very choice and rare. The plant appears to have flowered in Paris in 1663, and at Leipsic in 1700. In 1729, and again in 1743, two plants flowered at Hampton Court, it still being considered a great rarity.

There is a popular notion regarding the *Agave* that it flowers but once in a hundred years. The plants cannot be said to flower more than once during their life, but this flowering period may be at any age, and is influenced by the soil and position in which they grow. After flowering, the plants die, but new ones are produced by suckers. Though the *Agave* itself is of comparatively slow growth, the flower spike, which shoots up from the centre of the tufts of leaves, on the contrary grows very rapidly gaining a height of from 20 to 30 or even 40 feet, from the upper portion of which small branches are given off, which are crowded with yellowish-green flowers. At the base these flower spikes are nearly as thick as the wrist; the longest one ever recorded was 40 feet, and grew in the King of Prussia's garden. The flower spike which runs to this great height is a very striking object, being of a remarkably straight growth, and remaining in flower for several weeks; it contrasts favourably with the great fleshy, rigid leaves, which apparently spring from the ground without any stem intervening; these leaves sometimes grow to a length of 6 feet, and remain perfect for many years. Interspersed through the fleshy substance of these leaves is a large quantity of strong fibre, much used for a great variety of useful purposes in all countries where the plant grows. It makes excellent twine and cord of any thickness, and is exceedingly strong and of a very clean appearance; the fibres themselves are very regular and even. Hammocks are constantly made of this twine, and very strong and durable articles they are. The fibre has also been imported into this country of late years under the name of Mexican fibre, and it is much used in the manufacture of nail-brushes, scrubbing-brushes, and similar articles. Humboldt speaks of a bridge in Quito over the Chimbo, the span of which was upwards of 150 feet, and the principal ropes, which were 4 inches in diameter, were made of this fibre. It is separated from the fleshy part of the leaves by bruising them, then macerating them in water, and afterwards beating them. This fibre has also been used for paper-making. Important as is this product of the plant, the most valued of all is the sap, which when fermented is known as pulque in Mexico, where it is much used as a beverage.

There are three or four species of *Agave*, all of which yield a vinous

sap, but *A. Americana* is the most important; of this, however, there seems to be many varieties, for in a very lengthy report received at the Foreign Office from the Consul at Mexico upon the cultivation and uses of the plant, he says that as many as ten varieties yield neither juice nor fibre, and are consequently of no other use but for making hedges; he then enumerates twenty other varieties, each yielding juice in greater or less abundance, or of different degrees of quality.

The introduction of the use of pulque into Mexico is said to have been "between the years 1045 and 1050, in the reign of the eighth king of the Tlaltec tribe, named Tepancaltzin, at whose court a relation of his, named Pepantzin, presented himself, and informed him that his daughter had discovered that a sweet and aromatic liquid sprung forth from the *Mel* plants in her garden. The king ordered her into his presence, and she brought him a 'Tecomel,' or vase, of the liquid she had discovered, which he tasted, and then ordered her to bring him more; and subsequently becoming enamoured of the maiden, whose beauty was great, and whose name was Xochil, or 'flower,' he married her; of which union a child was born, to whom was given the name of Meconetzin, or son of the *Mel*, or Maguey, in allusion to the circumstance which was the origin of his parents' first interview.

"Whether the discovery of the use of the juice of the *Maguey* be really attributable to the god Izquicatl, or to the queen Xochil, there is no doubt that the divers properties of the plant itself were known many years before the discovery of Mexico by the Spaniards, for not only is it mentioned as furnishing thorny scourges as well as whips made of the fibres of the plant's leaves, for the multitudes who annually met to celebrate a festival in honour of the god Texcatlipuca, in the great temple of Tenochtitlan (the modern Mexico), but the use of the juice became so general that many severe laws against the drunkenness resulting from it were issued by the ancient Mexican kings, mention being made of a widow who sold it promiscuously having been put to death by order of the king Netzahualcoatl—only women sucking infants, old people, and soldiers upon the march, being allowed to drink it.

"To the various uses to which the *Maguey* plant was turned by the ancient Mexicans, and which were so much commented upon by the writers of the period, may be added that of the making of paper from the skin of the leaves, many curious old documents still existing of that material, as well as the manufacture of a kind of soap from the root. As to the extent of the lands appropriated to the culture of the plant, the writers in question give scanty information, but still sufficient to show that it was cultivated on an extensive scale in various districts of Mexico, where the vassals paid a great part of their tribute-money in clothes and sandals made of 'ixtil,' or *Maguey* fibre, and it is worthy of observation that the districts in question were the most thickly populated of the ancient Mexican territory, which is stated, perhaps somewhat vaguely, by the old Spanish writers to have contained more than 30,000,000 inhabitants."

"Dr. Hernandez, a botanist who was sent to make researches in Mexico by Philip II., in the year 1570, makes mention of ten different species of the *Maguey* plant as existing within the Mexican territory, assigning to each, under their Indian names, some peculiar medicinal properties or domestic uses, while ancient tradition, as well as the assertions of such of the rural population as are employed in this branch of industry, testifies to the existence of thirty different varieties of the plant in the chief *Maguey*-producing district of the plains of Apam.

"The plant may be cultivated to a height of 10,000 feet above the level of the sea, but is cultivated with greater success at a somewhat lower elevation, about 9,000 feet, but ceases altogether to grow at 5,800 feet. It requires an average temperature of 15° R. (60° F.), and flourishes from that to 26° (92° F.), the most favourable quantity of humidity in the air being about 35° to 50° of De Saussure's hygrometer in dry weather. For the complete development of its flowers it requires about 62° of heat (Centigrade) as a diurnal maximum. The juice of the plant is the least mucilaginous in a somewhat clayey soil, but if the soil be too dry, so many mucilaginous particles are secreted in the juice that an inferior kind of pulque, called 'ilachique,' can alone be manufactured from it.

"The vast *Maguey* district (calculated to comprise 600 square leagues) is now entirely destitute of trees, although vestiges remain of cedar forests having formerly existed there, the soil being light, stony, and apparently arid in many places; indeed, nothing can be less agreeable to the eye or promising in its general aspect than these or any other *Maguey* plantations, although so surprisingly productive."

There are few branches of agriculture, indeed, so productive in any country as is the growth of the *Maguey*, as is proved by the calculations given in the report from which these extracts are made.

"The mode of propagation of the *Maguey* is extremely simple. Before it dies the plant leaves a family around it of six, eight, or more suckers, which are left to grow for two or three years, and then dug up with great care, so as not to injure the stem; and after all the leaves but three have been cut off, the plants are spread out on the ground for two or three months, in order that they may partially dry, for if the *Maguey* be planted too moist it rots, and a destructive worm is often generated in it. The young plants are afterwards planted out at little distances apart, and in rows—harley, which is believed rather to favour their growth, being very commonly sown between. The formation of the leaves of the plant is admirably adapted for supporting all meteorological variations. A hail-storm which would suffice for the destruction of the maize or corn crop, scarcely leaves a trace of its passage upon their hard tissues; rain falls off from them, sun does not parch them, neither does frost dry them up or cause them to wither; and the plant would appear, as it were, to secure just so much of the various elements of the atmosphere around it as is necessary for its nurture and development, and to cast off the rest. It is only towards the close of its life that it begins to exhibit symptoms of being affected by the influence of the different seasons, yielding less juice in cold, rainy, or tempestuous weather. In a good soil the *Maguey* plant requires a period of from ten to twelve years for attaining maturity, but at least fifteen years in soils of an inferior quality; and thus the capital which it represents, although eventually yielding so high a return, remains unproductive for a lengthened period." The plant, upon attaining its full growth, which is easily discernible by its height and the prodigious extension of its leaves, brings forth a tall stem crowned with yellow flowers, and then a certain amount of pruning becomes necessary, so as to form a kind of reservoir in the centre, and what is technically termed a "cara" or face around it, so as to cause the juice to flow towards the same spot, and to facilitate the extraction of it by removing some of the interior leaves and thorns.

The belief which exists in the efficacy of the medicinal properties of the plant is universal among the Mexican peasantry, to whom it has been handed down from times of remote antiquity. Thus the juice of the leaf is said to be a specific for bruises and contusions; the gum which is engendered in the lower part of the stem to be a cure for toothache; whilst various experiments upon the curative properties of the plant under different forms have been made by members of the medical profession in Mexico with satisfactory results.—*Gardeners' Chronicle*.

RAILWAY PLANTS BETWEEN LONDON AND LEATHERHEAD.

I am this evening in possession of a treat that very rarely falls to my lot, that is, the opportunity of spending the evening by the fireside; and I do really find it very difficult to resist the inclination to have forty winks after being hard at work in the open air all day, but I will try to resist the temptation, and on this identical sheet of paper, which already bears the impress of my pen, I will mention to you a few plants that for several years past have given me much pleasure in my railway journeyings between London and Leatherhead. First, there are rich masses of the common Coltsfoot (*Tussilago farfara*), growing on the banks between New Cross and Forest Hill. On bright sunny days in the early part of March, the dense patches of this singular flower are really gorgeous. It is difficult to conceive anything more beautiful than several square yards covered with the rich orange of its flowers, which is only displayed in perfection when the sun is shining in unclouded brilliancy. And the singular habit of this plant, protruding its flowers from the creeping underground stem before any leaves have made their appearance, renders it an object of great interest to the botanical student. There are on many parts of the banks, both right and left, many interesting Hawkweeds, which in the latter part of the summer unfold their golden charms for the admiration of the passer-by. The ever-beautiful Furze (*Ulex Europæus*) is very frequent on the banks between these two stations. Passing on, there is a little nook between the Sydenham and Penge stations which contains a good many common Primroses, which in the season are very interesting; this is the only patch that I know of all down the line where there are enough of them to produce anything like effect; besides these, they only occur in isolated instances. The patch occurs on the left from London, about midway between the stations. There is not much variation in the character of the plants until passing from Norwood to Croydon over the rail crossing the main line. The bank over which the train runs, is at some points beautifully covered with Mare's-tail (*Equisetum arvense*). In the early stages of its growth, before being browned by exposure to wind and sun, this is one of the most graceful and interesting plants our island produces. Poppies are somewhat abundant, and very effective, on both sides of this steep embankment. The common Marshmallow is in patches on the chalky soil of which this bank is composed, producing flowers of a richer colour than I recollect to have seen elsewhere. Passing on, there is growing on the right, between Waddon and Carshalton, large patches of what I take to be *Gnaphalium sylvaticum*. I have never had the chance of examining it, only as the train passed along; and have never had the opportunity of asking any one to procure me a specimen. I should like to be certified what it is. Just before arriving at the Carshalton station, there are on the right two or three very dwarf bushes of the common thorn, which are really surpassingly beautiful; they are not larger than a small gooseberry bush, but are in the season perfectly covered with blossom, each of them a perfect galaxy. I have gazed on a good many beautiful things, but I have never seen anything more enchantingly beautiful than these bushes when in full bloom. They may easily be recognised; one of them is growing at the foot of one of the telegraph posts. A little beyond the Carshalton station, among the chalk, still on the right, there are some lovely patches of Viper's Bugloss. Drawing towards Sutton, still on the right, there are two plants of *Lythrum salicaria*—one growing close to the rails, and not easy to see in consequence; the other growing on the steep slope of the bank, about two-thirds of the way between the two stations. This last mentioned is a really beautiful plant, the finest I have ever seen anywhere. It is so stately, and its appearance so imposing, that it is invariably spared by the barbarians who ruthlessly mow down the thousands of beautiful succory and other plants which decorate this part of the line. It is a wish to call attention to this unique specimen which has induced me in part to pen these lines to you. I have been told that there is a large patch of Vervain (*Verbena officinalis*) growing close to the bridge near the Cheam station. I have not seen it, but I found a solitary plant of it growing by the side of the road, about midway between Ewell and Cheam, one day as I was walking. I also found a solitary plant growing on the margin of the bank surrounding the station-master's garden at Cheam (who, by-the-bye, is an old gardener, well up in a knowledge of plants, and is a diligent student of entomology). Near to where I found the first-mentioned plant, I found a large patch of the ever-interesting and graceful *Bartsia odontites*. On the left hand side of the road leading from the Cheam station to Banstead, there is a continuous hed of the pretty little yellow Rock-rose (*Helianthemum vulgare*). On leaving the Cheam station, there is a triangular piece of ground surrounded by rails; the fore-mentioned road may be reached by turning short off to the left, where there is a slippery path along the bank, which lies at an angle of 70°; but if the visitor is unable to maintain his equilibrium on a path of this sort, or has twisted ankles, or does not want to have them twisted, the best plan will be to walk round the railway, and passing under the bridge, he will not be long before finding this delightful little plant. I also found a solitary plant of it near Burrough Heath. On various parts of the line, the lovely *Calystegia arvensis* springs up among the stones, and is of a particularly beautiful colour. On both sides of the lower part of the line, the lovely blue of the Succory is of frequent occurrence, and positively enchanting. I think I have seen the White Moth Mullein (*Verbascum blattaria*) in one or two places between Waddon and Carshalton, but owing to the rapidity of transit I have not been able to observe it with sufficient steadiness to be able to say with certainty. There are many other plants which to me are objects of very great interest. I must not forget to mention a splendid copper beech in the front of a mansion which comes into view just before entering the Ewell station. This tree is a model of perfection, large in size, beautiful in profile, and in contrast with the other trees in its neighbourhood, looks like an immense *Perilla Nankinensis*. This tree cannot be too freely in-

troduced into park scenery, on account of the beautiful effect it produces all the spring, summer, and autumn, in contrast with the various shades of green of other trees entering into the composition of such scenery.

On nearing the Leatherhead station, there are, both right and left, some meadows covered with cowslips, which are in the season very cheerful and interesting. There is a meadow close behind the station which is covered with Adder's-tongue (*Ophioglossum vulgatum*). This plant, of course, is not observable from the line, but on turning aside into the meadow, in the season, it will be found abundantly over the entire surface. With the mention of another plant, of the *Allium* family, I will close this rambling paper. I have not seen it growing, but it was brought to me by a person in the neighbourhood accustomed to work in the fields. The flowers are white, produced rather numerous on loose panicles nine inches in height, and are very showy and interesting. The leaves resemble in size and shape those of *Colchicum autumnale*. I had not seen it before. Probably it is *Allium ursinum*. Some of your readers will think me a simpleton for noticing and writing about these things, but it gives me indescribable pleasure to look at them, to think about them; and it has kept me from going to sleep for a whole evening to write about them.

The locality from which I am writing is rich in objects of interest to the lovers of plants. I have already found—No, I will not anticipate; but when I have been here a little longer, and seen a little more about me, I may occupy myself some leisure evening in writing the account of my observations, instead of going to sleep.

WILLIAM CHITTY,
Knockholt, Surrey.

ADVANTAGES OF PLANTING EARLY WHOLE POTATOES.

About twenty-four years ago I planted several rows of the same variety of potatoes, some with small cuts, some with large cuts, and others with small, large, and whole potatoes. When dug, it was ascertained that the largest whole sets yielded the weightiest crop, and the small cut sets the lightest. Since that time I have been in favour of planting large whole potatoes, notwithstanding the large proportion of unsaleable potatoes generally produced by planting them. Perhaps this is one of the reasons that cut sets are generally resorted to by the great majority of farmers and others. With the view of improving the quality and increasing the quantity of those raised from large whole sets, about seven years ago I caused all the stems except the best one to be pulled from each of the sets while the potatoes were being hoed, and in this I succeeded far beyond my expectations. From a series of trials I have found that it is most unwise and most unprofitable to plant cut potatoes of any kind, and more especially those of the early sorts, which are frequently disbudded twice and sometimes thrice before being planted, consequently the sets are so much drained and weakened by the cutting and disbudding, that many of them perish from exhaustion or dry-rot, and those that grow are generally weak and unproductive. Besides, cut potatoes, although not destroyed by disbudding, are frequently damaged with dry-rot when planted in drills that have been much exposed to the sun, owing to the sap of the potatoes being absorbed by the dry material in which they are planted; hence the propriety of planting whole potatoes, to avoid the risk of being so damaged. Early potatoes would be much more productive than they usually are if proper means were taken to prevent them from sprouting before they are planted. This may be accomplished by storing them in cold cellars, or in dry ground sufficiently deep to exclude the heat of the sun from them, or in an outhouse where they must be frequently turned to prevent them from sprouting.

I have long been impressed with the idea that good results would follow from autumn planting, especially of early potatoes, in dry ground where the tubers would remain fresh and without budding until the soil becomes more or less heated. If they are planted 5 or 6 inches deep, they will not be injured by frost; although they should be frozen, the frost would leave the potatoes undamaged at the same time as it leaves the ground, provided that they are excluded from the sun and air. They will, however, not be so early as those of the same variety taken carefully from a pit or other potato store, with sprouts on them, and planted about the beginning of April. Some persons may doubt this, but they have only to make one fair trial to be convinced of the truth of this assertion.

On the 20th of April of this year, I resolved to ascertain, by a fair trial, the difference of planting cut sets to those of whole sets. The potatoes used in the trial were Smith's Earliest, which had been left in the ground during the winter, having been missed by the digger, consequently they were fresh and in good condition, from which I selected 72 sets—24 of them being cut sets weighing 1½ lb., 24 small sets weighing 2 lb., and 24 large whole sets weighing 5 lb. The whole were planted at the same time, and on the same ground, and grown with the same quantity and strength of liquid manure. The cut sets were planted in two drills, 10 feet long by 2 wide, and 10 inches apart. The small whole and large sets were planted respectively in two drills adjoining each other, of the same dimensions in every respect as those referred to; and of course the large whole sets, as well as the small whole sets, were set only 10 inches apart, the same distance as the cuts. It will thus be observed that 24 of either of the sets only occupied 40 square feet of ground. During the time of hoeing, all the shaws were pulled away from each of the whole sets, except one, and that one had had ample room to grow; indeed, I am convinced that if they had been planted 2 or 3 inches wider, the crop would not have been so good either in quality or quantity.

There is little or no danger of damaging the crop in the removing of the superfluous shaws, and the cost will not exceed in any district of this county 6s. per imperial acre.

The potatoes were dug on the 6th of August last; the produce of the cut sets weighed 15 lb., of the small whole sets 23 lb., and of the large whole sets 31 lb.—each of the lots being raised on 40 square feet of ground. At the same rates, an acre would produce from the cut sets 72 hags (or 115·2 stones), from the small whole sets 111 hags, and from the large whole sets 150 hags. The proportion of cut seed required to plant an acre is 6 bags, of the small whole potatoes nearly 10 bags, and of the large whole potatoes 2½ bags. The same variety of potatoes planted were sold this year by retail at 3s. per stonc. At this rate the cost would be (per acre), for the cut seed, £14 8s.; of the small whole seed, £28; and of the large whole seed, £57 12s.

Supposing the produce to be sold of the different sets at the same price per acre, they would realise respectively £172 16s., £236 8s., and £360. It will thus be seen that after deducting the extra price of the seed, labour, and per centage thereon from the latter sums, that a handsome balance will be left in favour of the whole sets.

It has often been asserted by persons who are looked upon as good autho-

rities that the only way to avert the potato disease is to plant none but those that are ready for storing in July. Upon this plan I have acted for the last sixteen years, and during that time I have not lost one potato by the disease until last year, when I met with a considerable loss, owing to having been too long in digging them.

The potato best suited in my opinion to avert the disease, and to remunerate the grower, is "Smith's Early," frequently called "Smith's Curly," probably from its producing long narrow curly leaves similar to those of the ashleaf kidney. It resists spring frosts better than any other variety known to me, and produces a large quantity of peach-coloured bloom about the beginning of June—a thing not common to early potatoes. It is, however, the earliest potato that I know of, being round in form and of a large size. Some parties in this district, however, have not succeeded so well as could be desired in the growing of this potato, having cut their sets after the sprouts had been once or twice broken off them; therefore, nothing but a poor blanky crop could be expected. If growers treat them in the way recommended, they will be amply rewarded. JAMES DOBBIE, *Renfrew*.

Calendar.

WORK FOR WEEK COMMENCING JANUARY 19TH.

Kitchen Garden and Frame Ground.

CAPSICUMS, TOMATOES, AND EGG PLANTS to be sown at once, and placed in heat. Use light rich soil, sow thin, and prick the plants out to strengthen as soon as they are large enough.

CELERY to be sown for early supply. A small pan of seed will be sufficient for the wants of the largest family for a first sowing. Let the soil be rich and fine; the seed to be very lightly covered. If the soil is reasonably moist in the first instance, it will not require to be watered till the plants are up. To prevent evaporation, lay a square of glass over the pan after sowing the seeds.

RHUBARB in the open quarters to have six inches of rotten dung heaped over the crown of each plant. Rhubarb may be planted now, and old stools may be divided.

KITCHEN CROPS of every kind required for spring sowing may be sown in very small breadths, and with the exercise of judgment as to the prospects of the weather.

CABBAGE occupying plots of ground which will be required shortly for some other crop, may be taken up and laid in by the heels in some out-of-the-way place till wanted for the kitchen. As the plants do not grow at all at this time of year, nor for several weeks to come, the ground they occupy may be taken possession of at once if required to be got ready for another crop. This remark applies of course only to cabbages of a size fit for table, and that would probably be cut for the kitchen during February and the early part of March; store plants for planting out in spring must be let alone for the present. If any likelihood of requiring early supplies of summer cabbage, sow now a few of the early heading kinds in boxes or pans, and start in a gentle heat. At the end of February these will have to be pricked out into a sheltered bed out of doors, or better still into a bed over which a frame can be placed for a few weeks to help them on and protect from frost.

CAULIFLOWERS.—Sow in boxes, and treat as advised in foregoing paragraph on cabbage, remembering that these are more tender in constitution, and will require a little more nursing.

LETTUCE.—Sow in boxes as advised for cabbage and cauliflower.

PEAS AND BEANS pushing through the ground need some protection both against frost and vermin. If the weather is mild and open, the best you can do for them is to sprinkle slightly with soot, or plentifully with wood ashes. This will keep off slugs and snails, which, if they wake at all now, are sure to search out the peas and beans for breakfast. If the weather is cold, and likely to be severe, strew over them any light dry warm material that may be handy, such as chaff, waste hay, or even dry fine earth. In places exposed to the wind, branches of spruce thrust in against, so as to overhang the rows, will be protective, and may save many a promising piece of plant from destruction.

POTATOES of early kinds that have made short, hard, purple sprouts in the full daylight may be planted at the foot of a warm wall, or in any other well-sheltered and sunny position for an early crop. To force potatoes it is only necessary to have a gentle bottom-heat from a large mass of fermenting material, a bed of light rich earth containing a good proportion of leaf-mould and chred rubbish, and some old frames and lights. Of course they must never be exposed to frost or excessive wet; but as soon as the season is sufficiently advanced, they must have as much light and air as can be given with safety. It is most important to protect the roots from the steam of fermenting dung; in fact the potato murrin many be engendered in a forcing frame by shutting the plants up close over a steaming hotbed.

CELLARS.—The foetid air from decaying vegetables is as bad as the malaria from a swamp; hence be very careful in storing vegetables and in frequently examining those already in the cellar, to remove all roots and leaves beginning to decay. Thorough draining, ventilation, and plenty of lime whitewash, are good, both for the things kept in the cellar, and for those living above it. A little hydraulic lime mortar, with bits of stone and broken glass, are good stoppers for rat-holes. The best cellar temperature is one as low and equable as possible above freezing—in fact, a little frost is better for apples than too much warmth. Potatoes endure rather more warmth than apples and other fruits. Sashes with double glass and an intervening thin space of confined air, are nearly equal to stone walls in shutting out cold. Protect the exposed walls with a bank of earth outside, or what is neater and better, spent tan-bark, if it be conveniently accessible.

HOTBEDS should now be made up for every kind of early work. In many districts it is no easy matter to get hot dung for the purpose, on account of the immense demand from the beginning of February to the end of April. This is especially the case in suburban districts where gardening is pursued with ardour. Where there is any such risk, the amateur should remember that every scrap of dry fibrous material can be made available to increase the mass for the production of heat. Straw, fern, mouldy hay, leaves, &c., are all of value to mix with dung, for the continuance of the heat depends entirely on the bulk of undecomposed fibre in the mass. Large quantities of material available for hotbeds are ruthlessly wasted in private gardens, simply to get it out of the way;

but wherever conveniences exist it should all be saved, and in many cases the mass of a fermenting heap may be doubled or trebled by this economy.

WORK FOR BAD WEATHER.—Very shortly there will be a demand for clean pots, clean crocks of various sizes, flower-sticks, labels, and all sorts of mending and patching of lights, frames, &c., &c. While the ground is covered with snow, or frost, or wet, put a stop to outdoor work. Many of these odd jobs may be comfortably done in the potting-shed, where perhaps there is warmth enough from the furnace fire to make work pleasant to the servant, which is one step towards making it profitable to the master. Gardeners are not sufficiently thoughtful of their health and comfort at this time of year, hence many an illness, and many a permanent lodgment of rheumatism in the limbs. Suit the work to the weather for all hands, and save up for such times as these a few jobs that may be done under cover, and which, if well done, will save much hurry and confusion, and neglect of important work when spring with its ten thousand demands on thought, and strength, and time, breaks upon us suddenly and finds out all our dilatoriness.

Flower Garden.

PANSIES for exhibition will have to be repotted shortly, and it will be well to prepare for the operation by providing suitable compost. The Pansy never thrives in a heavy soil; in all places where they master this flower they use a sandy loam, to which is added a good proportion of leaf-mould and some thoroughly decayed hotbed manure. Let the mixture lay up some time before using, as its qualities will thereby become better blended. As a recipe for a compost for pot Pansies may be useful to beginners, we advise that it consist of light hazel loam two parts, decayed turf from pasture-land or very sweet leaf-mould one part, two-year-old cucumber-bed manure one part, sharp sand one part.

TULIPS pushing through will need some protection to prevent injury by frost. Light soil heaped in cones over the plants will suffice; better still cones of coconut fibre refuse.

ROSES to be planted as soon as possible. In light soils, standards will thrive better if some clay is dug in with the manure. Roses on their own roots need a lighter soil than brisars. Roses will never thrive unless the ground is effectually drained, deeply stirred, and liberally manured.

TULIPS breaking ground now are likely to suffer by frost. Heap cones of sand around them before the crowns open, and cover with mats on hoops while the weather continues severe.

DAHLIAS may be started in a gentle heat for cuttings. The simplest way is to lay the tubers on the soil over a tank in an propagating house, or on a bed of warm hops or dung, and when the shoots are two inches long take them off and strike them.

HOLLYHOCKS in cutting pots to have a shift to 48-sized pots, and the soil to be chiefly loam. Keep them in the greenhouse or warm pit for a week after shifting, then they may go to a cold frame. Strong plants in pots may be planted out.

HERBACEOUS CALCEOLARIAS are now among the most gorgeous of all the herbaceous plants we possess for the decoration of the conservatory and greenhouse during summer, and to do justice to them they should never be put out in the open air. Now is a good time to get in stock of the named kinds, and to sow seed for new varieties. Plants in store pots to be shifted, and the compost to be chiefly turfy loam, with not more than a fourth part of peat and leaf-mould added. Experience has taught us that a firm soil, containing plenty of fibre, causes them to throw finer trusses, and be less subject to red spider, than when peat is largely used. It is a good presention against the possibility of damping at the collar to use a very sandy mixture at the top of the pots about an inch in depth.

ANNUALS to be sown in plenty for early bloom. There are a few choice kinds which should be grown to bloom in large pans or in pots for the drawing-room, such as *Nemophila insignis*, *Fenzlia dianthiflora*, *Iberis Kermesina*, *Gypsophylla muralis*, *Silene armeria*, *Mignonette*, &c., &c. Sow also in beds and borders any of the Californian kinds. Half-hardy annuals should be sown now in heat, such as *Thunbergia*, *Schizanthus*, *Phlox Drummondii*, *Balsams*, *Datura Wrighti*, *Eccremocarpus seabear*, *Ten-week Stock*, *Cockscomb*, *Celosia pyramidalis*. It is a waste of seed and labour to sow Asters at this early season.

EVERGREEN SHRUBS had best not be transplanted or in any way disturbed for a few weeks hence. After December we prefer not to move them till between March and May, as the ground is now so cold that they cannot make new roots in it.

LAYERING of hardy shrubs may be practised now for increase of stock, and to furnish the lower parts of specimens on lawns in cases where they have become unsightly through the loss of wood at the bottom. The operation is a very simple one. Draw down a suitable branch and peg it to the ground, to mark where the tongue should be cut. Then enter the knife on the under side, and make an incision half through the wood, and turn the knife towards the top of the shoot, and cut a slit an inch or an inch and a half long. Remove a little of the soil, and peg the branch down with a bit of tile or pebble inserted in the cut to keep the tongue open, and peg it down firm, and cover the tongue with an inch or two of soil. If the cut closes, the cut will probably heal; if it remains open, it will in the course of the summer emit roots, and may either be left to throw up new growth to increase the bulk of the specimen, or be removed to form an independent plant.

RANUNCULUSES.—In planting ranunculuses, some growers mark off the bed, and then just stick the claws of the tubers into the soil, and cover the whole with sand; others dibble them in, in the way that beans are sown by farmers; but the best plan is to drill them. Choose a fine day; have your tubers sorted as you mean to plant them, and your zinc or wooden tallies ready. You have already at the fire-side planned how the colours and sorts are to be arranged, and have entered in your note-book all necessary heads, so that when you begin planting you will have to work only, and not to consider. First rake the soil so as to give the bed a gentle convexity; then put down the line for the first row, and with a small-pointed hoe, or the corner of a common one, draw the drill exactly two inches deep. The orthodox depth is an inch and a half, but I prefer, and therefore recommend, a trifle deeper, on the principle of giving the root free work before the foliage appears, as well as to escape as much as possible the effects of the very late frosts to which we have been subject for some years past. Into the drill sprinkle a very little fine sand, then proceed according to your book, and plant the first row of tubers, inserting the proper label at once, not trusting to memory a single jot. Each tuber must be gently pressed into the soil to about half the length of the claws,

care being taken that none of the claws are broken in the process. The drills may be five inches apart, and the roots four inches apart in the drills, though some growers prefer six or even eight inches distance every way. The first mode will not be injuriously close, and it forms a very rich bed. When the drills are filled and tilled, sprinkle a little sand over the tubers, and then neatly rake down the soil over them, and dress up the bed as you intend it to remain. It may be as well to state as a last word on this point, that if the roots are planted too deep, they will not flower, for instead of throwing up the flowers they will exhaust their energies in forming new tubers near the surface. Be careful, therefore, never to make the drill more than two inches deep. As soon as the plants begin to push through, the bed should be carefully trod over between the rows, firmness of the soil being a prime element of success in the general cultivation. If the weather is dry, they may be watered night and morning, and if the soil has not been so liberally manured as it ought, weak manure-water may be used. The ranunculus likes a moist and generous soil, but nevertheless it is a mistaken notion to water it either frequently or copiously. Artificial watering never does as much good as is expected of it, and if it can be dispensed with it will be better for the plants. It is a good plan to mulch the bed with moss or old tan, or even ancient and well-sweetened manure, placing the dressing neatly along the rows. Such a procedure will frequently obviate the necessity for watering, and carry the plants through till the rain falls.

Fruit Garden and Orchard House.

VINES not yet pruned must be pruned without delay, or the usual result of late pruning—that is to say bleeding—will follow, and this will injure the vine immensely. Vines started will require care during changeable weather to prevent injury of the young leaves by frost or fire, and especially to guard against too high a night temperature. All shoots not required for wood, and on which no fruit appears at the proper time, to be removed as soon as possible; and in cases where fruitful shoots are much crowded, some must be removed—as, for example, it is not well to allow two shoots at one joint, or a cluster of shoots where there is a bend in the leader, as it is quite common for extravagant growths to take place at such points.

FRUIT TREES are on the move, so every delay now in planting and pruning will be injurious. Let any arrears of this work take preference of every other.

WALL TREES may now be pruned and nailed in. Use shreds as small as possible, and prepare the nails by making them red-hot, and throwing them into oil.

ORCHARD HOUSE.—The litter may now be removed from amongst the pots which have been so protected. If the trees look at all shrivelled, give each pot a quart of water, choosing a fine morning for the job. Prevent, by freely ventilating, any undue rise of temperature on fine bright days, and, if possible, keep all quiet till the end of February.

PLANTING must of course go on where it has not yet been completed, and in many places there will be a rush now that February is near at hand to get the work completed quickly, without much reference to the mode of doing it. But as the latter part of January is one of the most uncertain times of the whole year, the planter must be cautious, and avoid taking up more trees or making larger purchases than he can deal with quickly and completely, for in the midst of the work may come hard frost, a deluge of rain, or long-continued snow. Better let the trees lay in by the heels a few weeks than plant them unless the ground is really in a proper condition; if the soil is wet or frozen, all the planting done will be badly done, and the trees will not prosper.

Greenhouse and Conseratory.

GREENHOUSE must have ventilation, or mildew and damping will prevail, and many plants pushing their flowers will cast them unopened. But to give air there must be fire, so for the next few weeks keep the fire going whether the temperature be mild or severe; in the case of mild weather, give plenty of air, and have a look round to see if any plants are suffering by want of water. Be careful not to maintain too high a night temperature, as that is most mischievous, and is the common failing everywhere, both in nurseries and private gardens.

ERICAS want great care at this season, as fire-heat is injurious, and damp and frost are not much less so. Whenever frost can be kept out by means of mats or allowing the fire to go out early, so as to leave just enough warmth to counteract a few degrees of frost, such a course should be preferred to firing. In mild weather give air, and at all times be careful to avoid stopping water about amongst them.

PELARGONIUMS for show must now be encouraged to push with the aid of an increased temperature and as much air as the weather will allow. It is common for them to be assailed with green-fly when the new growth of the season commences, but if the cultivator is on the look-out, and puts a stop to that pest in good time, it may be got rid of for two months to come. Keep as near the glass as possible.

Forcing &c.

ASPARAGUS will force much quicker now than the season for it to grow naturally is approaching. A temperature ranging from 45° to 60° will answer admirably; beyond 65° it should never be allowed to rise. When the heat goes down below 45°, apply a lining round the bed, and cover the lining with straw or thatched hurdles, to shoot off wet and prevent cooling down by wind or frost. Where heat from hot-water pipes is at command, forcing asparagus and seakale is so easily and conveniently accomplished that a child might manage it; with fermenting material the case is different.

CUCUMBERS not yet put out on the fruiting bed must be provided for as soon as they are ready, as the keeping them in pots a day longer than needful is an injury to the plant and a day lost in the cutting of the first fruit, which may make considerable difference in its value. It is important to have heat enough, and also important not to shut the plants up close in a mass of hot steam. If the heat is too fierce and rank, fork the dung lightly, and wait another week. It is much better always to pot the plants singly, and bed them out singly. The system of potting and planting in pairs is no gain in the end, as the plant naturally grows with such vigour when properly treated that single plants cover as much space in a given time as a pair would, for when in pairs they check each other by proximity, and sometimes get injuriously intermingled if neglected during a few days of good growing weather. Plants in bearing will begin to show a few vermin; search beneath the leaves, and if any red spider,

give more moisture and volatilize a little sulphur; if green fly, fumigate. When the roots appear on the surface after the plants have been some time in bearing, give them a dressing of fresh rich soil.

CHERRIES in the forcing house must be managed with great care, or the flower-buds will fall wholesale. Keep a genial and regular temperature of about 45°, letting it down to 40° at night, and after they have made a start raise the heat to 55°, which will suit them admirably for flowering. Let the atmosphere be rather moist at first, but dryer when the flowers begin to open.

STRAWBERRIES require as much air and sun as possible as soon as the fruit begins to colour. Use no more heat than needful to keep them in free healthy growth, or the crop will be worthless; this fruit cannot, in fact, be hurried. Usually a bottom-heat of 70° is advised, but from long observation we have become convinced that 60° is far better, because we not only want fruit, but we want it with colour and flavour, which we cannot have with hard forcing. A plunge-bed of 60°, and the air of the house 45° to 60°, the latter of course with sun-heat, will be suitable temperatures. Feed them well; nothing like sheer solution of dung after the first few fruits are set. But beware of making them too wet at the root, which will be injurious.

PEACHES and other trees in flower may be greatly helped by shaking the trellis, or whisking a light brush over them, to disperse the pollen. Any rough play with the trees will do more harm than good, but any slight agitation, such as a stiff breeze on a sunny day would produce, will assist materially in setting the fruit.

RENOVATING UNSIGHTLY TRAINED ROSE TREES.

When against walls of a good height, rose trees are sometimes very liable to become too naked and unsightly all along the lower portions; even the most careful cultivator cannot always ensure a nicely trained rose tree, and, at the same time, one well furnished with leaves all over its lower portions. It is to be observed, many trees when trained against walls are very liable to run ahead, and thus become too naked about their stem. A little judicious treatment, at a proper season of the year, would go a good way to remedy the unsightly appearance, and be a means of giving quite a fresh look to the tree. There are two ways which we have acted upon, the one differing somewhat from the other.

Firstly, supposing you have a rose tree trained against a wall, covering the latter well for some feet or yards on each side of the root, upwards to the top of the wall—having been for years generally well furnished all over with spurs and flower-buds, but in the course of time the lower portions gradually lessened in their leafy covering, as well as in their apparent ability to produce flowers—if the spurs are not dead, it may be recovered by judicious pruning. Wait and see March well advanced before you attempt to prune it; and when you prune the first portion of it, let this be only the lower part of it, and let some weeks elapse ere you attempt to cut in the higher portion. Indeed, perhaps you had better let all the upper part break away into life before you prune any of the higher part. By doing so you will find that all the buds towards the base of the shoots or spurs remain dormant, while those more towards the points of the shoots burst away into leaf. Well, just let them do so; and in the end of April, or the beginning of May, cut back all those upper shoots to their proper position. By this way of acting it often happens that all the lower parts, where first pruned, will have time to bust away and go ahead before the upper portion can break forth from the eyes, close along the bottom, where you can cut it back to.

Another way can be acted upon; and this we have proved, in several places, to render great service in restoring unsightly rose trees, and to clothe again the lower portions with foliage and flowers. The mania house where we were was about to be renovated, and a portion of its walls painted outside, where there were several rose trees nailed up against the wall. These had to be unfastened, and laid backwards as far as they would admit of. A few stakes were firmly driven into the ground, and the roses tied slantingly backwards. This was in summer, and thus they remained, while the wall was painted over several times; and before all was ready for the rose trees being trained up again it was pleasing to see all the bare lower parts breaking out with a healthy and vigorous covering of shoots, which in due time repaid us with a nice crop of flowers; and by judicious management this kept the trees in very fair condition for several years. Since then we have tried the Gloire de Dijon rose, as well as several others. It is only to put up with the unsightliness of the trees being unfastened and brought forward for a few weeks at most; rather this than allow them to remain unsightly for a yard or two up the wall for years.—G. DAWSON, in "Scottish Gardener."

BIRD KILLING.

The following is the text of a letter addressed to the incumbent of Strood by C. Roach Smith, Esq., the eminent antiquary, through the medium of the "Strood Pariah Magazine":—

Reverend Sir,—All sensible people will feel pleased you have pronounced against what may be called the national vice of bird-killing. It is one of those vices which society does not care to recognize as a vice, because it is so common, and is tolerated or winked at. Where is the parent who does not take his children, for amusement, to find birds' nests, and to carry home with them the eggs and the young? Thus among children this hideous sin is universally indoctrinated as something harmless and pleasing. Thus the hardening of the heart is taught with the child's first lessons in reading and with its prayers; and it grows up callous to all the finer feelings of humanity, and becomes in its turn a "breeder of sinners." In a walk of two or three hours on a fine Sunday morning about two years ago, I saw from ten to twenty parties of boys and young men, actively engaged in birds' nesting. At a moderate calculation they destroyed that day full a thousand eggs and young; and this laughter went on, and yet goes on, in the summer seasons, daily, although Sunday is the favourite day with the large class of uneducated idlers. Even in some schools in this county, I am told, the children are urged to destroy the young of small birds to support by so doing the principles of those cowardly adults who at the festive board produce the heads of their victims as something worthy of boast. See the printed rules of the sparrow clubs. One of these established not far from Dartford is before me. Its objects are thus coolly set forth: "That this Club be established for the purpose of destroying sparrows, bull-finches, chaff-finches, blackbirds, and thrushes, which

abound in and about the various parishes." Then come the "Rules" regulating the number of heads to be produced at their nights of meeting, &c.; and their club also prints the names of its chairman, treasurer, and secretary, who no doubt glory in thus seeing their names in print. But the killing of birds goes on throughout the year. In the winter months when they at times become deprived of food, then their enemies, men and boys, are upon them; and with merciless severity, as if they were hunting noxious animals, shoot them down, or net and trap them. Those who catch them on a wide scale in nets are, I am told, persons who mostly live by poaching, but who somehow ever contrive to avoid legal punishment, and are countenanced at times for frauds of a certain kind, such as stealing evergreens at Christmas for the decoration of shops, houses, and churches. These persons can at any time produce for your table a hare or a brace of pheasants, and for a sparrow-shooting match will catch you any number of birds. I have seen them at work at night with nets catching the birds roosting in the ivy of the Stood national schoolrooms, and since writing this letter, in the ivy of the church. They can earn money easier in this way than by hard, honest working.

Can we wonder at the increase of the insects which destroy our fruits; and at the great loss sustained by those who have extensive orchards and gardens? The birds are the only possible agents to counteract the deadly unseen insects which are every hour being bred almost everywhere. Nature has formed the bird's eye for detecting insects where the eye of man is useless. Wholly destroy the birds, and the fruit is wholly destroyed. At Hartlip, some years ago, in the face of truth and facts, the sparrows were exterminated entirely as being injurious. The orchards were immediately covered with the webs and nests of innumerable caterpillars and other insects; and in two years it was calculated that over £1000 was lost in consequence of this insane slaughtering. But far more startling instances could be adduced; and yet we see no steps taken to stay the evil! I, sir, look more to youth than to the hardened man, who has steeled himself into erroneous convictions; and will never part with them but with life. It is not so with boys; they are to be reasoned with; and if the clergy and schoolmasters would make friends of them and explain the nature and use of birds and their importance in the great scheme of Providence, I am assured they would soon be induced to be protectors instead of destroyers of the birds; and they would thus find doing good much more grateful and profitable than working evil.

I am, rev. sir, yours very truly,

C. ROACH SMITH.

Temple Place, Dec. 18th, 1866.

Correspondence.

ALL PRIZES AND NO BLANKS.—It was with great pleasure I read your correspondent's very interesting paper on this subject, and hope the day will not be long ere we do see all have prizes that are worthy. If managers of exhibitions cared to give more satisfaction to exhibitors, we should have tables better filled with better produce; but I believe that is the very last thing they think about; in fact, it seems to be so while exhibitors are treated as they are at many of our exhibitions both great and small. To satisfy all, I know would be impossible, for we, like other communities, have men that are never satisfied. Perhaps those who exhibit as a trade would not care for your correspondent's "honourable mention" (which I think is a very valuable suggestion), but there are those who would prize them more than money. The humble cottager would be as proud of them as his richer neighbours are of their paintings and engravings. Parliamentary reform is not the only reform we want.

J. T., near Leicester.

CANADIAN FERNS.—Having already been fortunate in obtaining answers to questions in your excellent paper, I apply to you for the names of the few ferns, &c., enclosed. I have lately brought them from Canada, the neighbourhood of Ottawa, among several others, many of which, I am sorry to say, are not sufficiently unmutated to forward. The fern numbered 3 is similar to *Filix mas*, but differs very much in look and habit; in large specimens the stipes are very long. It may interest some of your readers to know what others I found, so I give a list: *Polypodium vulgare*, *P. dryopteris*, *Lastrea thelypteris*, *L. cristata*, *L. spinulosa*, *L. dilatata*, *Adiantum filix femina*, *A. Michauxii* (?), *Asplenium triebomanes*, *A. Adiantum nigrum*, *Pteris aquilina*, *Adiantum pedatum*, *Cystopteris bulbifera*, *C. regia* (?), *Osmunda gracilis*, *O. cinnamomea* (?), *O. interrupta*, *Onoclea sensibilis*, *Struthiopteris germanica*, *Botrychium virginicum*. I also enclose a frond of a variety of *Lastrea oreopteris* which I found this summer at the English lakes. As it is not mentioned in any list or work on British ferns, I think it may be a new variety, and as such interesting, being so strongly marked. The other frond enclosed is one of a series all more or less irregular; and I want to know if it is worth including in a dried collection of British ferns as something distinct.

A. S. M.

[No. 1 is *Polypodium dryopteris*; 2, *Polystichum acrostichoides*; 3, *Lastrea marginalis*, one of the loveliest of the genus; 4, the red-stalked variety of *Lastrea filix mas*, frequently met with in England. The variety of *L. oreopteris* is very distinct; you should have secured the plant.]

VEGETABLE MARKETS.—You have lately touched upon a subject which has interested me deeply, for since I came to London I have not known what it is to have enough of good vegetables on my table. Oh, how I miss the health-imparting fresh-gathered vegetables and fruits which my country garden afforded, for here I positively cannot purchase a supply of such as the shops offer, the prices are so exorbitant. How can it be otherwise, when no less than six greengrocers make a living, after fetching their goods all the way from Covent Garden? yes, six greengrocers within four minutes' walk from my house, in a not over-populous part in a London suburb $4\frac{1}{2}$ miles west of the Bank of England. I plainly see this great metropolis is destitute of markets, and that the market gardeners might do better for us than at present, for we Londoners are starved on butchers meat, bread, and potatoes; I say starved, for who can live properly if denied a sufficiency of good vegetables? If some of the bigwigs of the parishes who spend so much of their time in parochial squabbles would promote the formation of vegetable markets in the more populous suburbs, they would be doing much more good, I fancy, than by beating up a local celebrity by means of small querrrels and big words. You speak of Covent Garden Market as a "dog-hole;" well, as regards the supply of London, and as the central and grand market for London, it is a dog-hole, yet neither east, west, north, nor south does there seem to be enough spirit to start markets in opposition, either to reduce its pretensions or supersede its

questionable usefulness. The whole valley of the Thames ought to be occupied with vegetables and fruits for the London market, and if it were so every scrap could be sold for a good profit. But cultivators, equally with consumers, require more markets.

H. H.

PROTECTING FROM FROST.—I wish your Durham correspondent would say a little more about this matter. How are we to place mats inside a frame? How does Mr. Allason do it? As to the advantage when done, there can be no doubt; but then frames must be very differently constructed, or the matting would do more harm than good, falling about the plants. Some years ago I made some light protectors, like window sashes, of mere lath wood, and covered them with canvas, which I painted. These I used to lay on my frames and fix with a few nails, and they were very useful during frost. I should think they would be just the sort of things to put inside, and it would only be needful to nail a strip of lath along each side of the frame for them to rest upon. Better than all mats or calico would be double lights, with an inch of space between them. They need not both be of glass, as possibly oiled calico would do for these, put on merely to protect, though I should prefer glass, as in case of leaving them on longer than needful, the plants would not suffer for want of light. But here we get into expensive notions, and I say no more.

W. D.

EXHIBITION REFORM.—I quite agree with your correspondent who writes proposing to add "honourable mention" to the list of awards at flower shows. I accept his statement as an echo—and a most proper one—of the oft-repeated editorial statement that it is hard for many exhibitors to go empty away, and deeply injurious to flower shows. The fact is there is too much grab (pardon the vulgarism; it is the only word that can express my meaning) after money prizes on the part of big amateurs and big trade exhibitors, so that the small men are elbowed out. Now I say we ought to encourage the small men; the big ones can take care of themselves. It appears that so long as promoters can secure a show, they care not by what means they do it, even if there are but half a dozen competitors, and the tent is made use of as a shop. I know the value of trade exhibitors, and would not wish to limit their operations; all that is needed is more encouragement for the humbler class of amateurs who can only show small collections, and which small collections would oftentimes take the shine out of the larger ones in respect of quality. More prizes are, I am satisfied, of far less importance than they are usually considered; cups, or more useful objects in gold or silver, or even hooks or valuable plants, would be far better, and these might be backed up with "honourable mentions," as proposed by the writer above referred to. When you have many exhibitors, you not only have more variety, and do more good for horticulture, but you secure the interest of a larger number of persons, and out of that increased interest will arise increased success.

SIGMA.

Replies to Queries.

Salt for Asparagus.—J. G.—Asparagus may be poisoned by the excessive use of salt, as any other plant may, yet it will bear salting to a great extent without injury; and within a certain mark, salt is highly beneficial. The best mode of using salt is to sprinkle the surface of the bed every fortnight, merely applying sufficient to make a perceptibly white coating, commencing in the last week of March, and continuing the applications till the last week in July. If alternately with the saltings liquid manure can be applied, the growth will be much more satisfactory; indeed, it is by combining the two agents that the "giant" asparagus is grown for Covent Garden Market. Some cultivators apply a heavy coating of salt in March, and give no more till the stems are cut down in autumn; but this is an objectionable plan, because the plant has more salt than it can appropriate in the early period of growth, and scarcely any when it is in full vigour, and engaged in forming the embryo buds that are to furnish shoots for the next season. Where it is not possible to apply a thin sprinkling of salt every alternate week throughout the growing season, the system of heavy dressing in the month of March must be adopted, and the quantity applied should be at the rate of twenty-four bushels per acre.

Subscriber.—The articles on Seakale to which you refer are we suppose those published in the magazine of Feb. 4, 1865, and Feb. 18, 1865.

Rockery Plants, &c.—Miss Gurney is advised to apply to any of the nurserymen who advertise in this work. We do not know what is meant by the "Spider-web plant," unless it be *Ouvirandra fenestralis*, the management of which was described in the GARDENER'S MAGAZINE of Jan. 6, 1862.

Dahlias.—S. V.—In the issue for Sept. 8, 1866, we described all the seedlings shown at the Crystal Palace. We see no reason to repeat those descriptions.

Woodwardia radicans.—Lady B.—We cannot hold out any hopes that your large plants of this noble fern that have been left out will survive the winter. It has been tried many times at Stoke Newington, and has lived through mild winters with a heap of leaves over the crown, but severe frosts have always killed it; should yours be found alive next season, we shall be most glad to know. This and other nearly hardy ferns should be taken up and potted in October or November, and be kept in a cool house all winter, and be planted out again in April. They submit to this kind of treatment as patiently as common bedding plants.

BIRD PRODUCTION.—Artificial birds'-nests are now made in Switzerland under the direction of the societies formed there for the protection of insectivorous birds. One of the members of a society of this description, who inhabits Vevey, having observed that many species of that kind select for nests the holes they find in the trunks of rotten trees, and that they, consequently, do not find it easy to settle in orchards, where all the trees are in good condition, began, twenty-five years ago, to set up rotten trunks in his grounds; and since then he has had no need to trouble himself in the least about clearing away caterpillars, that care being left entirely to his winged guests, who perform their duty admirably. His neighbours, on the contrary, who have not had this foresight, have had their orchards laid waste by a host of voracious insects. The Yverdon Society have gone the length of placing artificial nests even in the public walks and communal forests, on the borders of the lawns, &c. All those nests are now inhabited by hedge-sparrows, redstarts, creepers, and tomtits, all which may be found in Switzerland as high up as the perpetual snow-line. The same practice has found its way into Germany.

The Gardener's Magazine.

SATURDAY, JANUARY 26, 1867.

ACCIDENTS ON THE ICE have been so numerous this season, and in one case—that in the Regent's Park—attended with such a lamentable loss of life, that we may properly offer a few remarks applicable to the particular cases which have filled the public mind with horror, and to the general subject of water as an embellishment of park and garden scenes. Probably to a large proportion of skaters, at least of the "male persuasion," there is a positive pleasure in skating over deep water which does not accompany the same exercise on shallow water. Judging by the behaviour of the crowds that have frequented the public parks of the metropolis during the past fortnight, an element of danger is essential to give a thorough relish to the recreation. Whether this be so or not, those who esteem life as of some value, and who object to men plunging themselves into deep water, and their lives and families into deep distress, by one and the same process, will be interested in any reasonable proposals for rendering perfectly safe the waters commonly resorted to by skaters, and for improving in this respect the usual methods by which ornamental waters are formed in parks and gardens. The majority of the proposals made in the daily papers since the terrible accident in Regent's Park, have for their main features the reduction of the depth of all the artificial lakes in the parks, and the covering of the bottom with stone flags or concrete. There can be no question at all that shallow lakes, with beds of stone in place of mud, would be far safer than such deep water as that which engulfed some fifty persons in Regent's Park, and for skating purposes would be admirable. But the proposal is open to several objections. To reduce the depth and have the bottoms of all the lakes in the London parks concreted would be a very costly proceeding. As we have good skating only about once in every four or five years, the expense would be out of proportion to the resultant benefit, save and except for this consideration—that to prevent loss of life, no necessary expense can be too great. But safe skating can be provided in a cheaper and more effectual manner, and therefore we may reasonably contrast the expense of paving the great lakes with the fact that it is only at distant intervals that skating is possible in England. The great cost compared with the rarity of benefit from it is therefore a serious objection. There are yet two other objections worth noting. Shallow waters never have the beauty that belongs to water of some depth. As embellishments of our parks, we desire to derive from great breadths of water all the enjoyment possible; and if the water is clear and deep, it has that steel-like lustre and darkness which makes it reflect every changing hue of the sky, and every object on its banks, in all the charming variety and changeableness which have made it, as a feature of rural scenery, the grandest of the elements. There is yet another object, which we admit is of secondary importance: it is that you cannot keep fish in shallow water. Nevertheless, this *is* an objection, and may stand for what it is worth.

Supposing skaters to be well provided for, it is possible a large number of them would prefer danger to safety. We found this conjecture on what we have seen, and heard, and read. But it is a question of police, not of landscape gardening, how people are to be kept from committing suicide when the skating frenzy seizes on them. The question is as to the substitute. This we think should consist of a space set apart in every pleasure ground expressly for bowls, billiards, and other games in summer, and for skating in winter. A flat grass lawn sunk one to two feet below the general level, and with sloping banks to define it, could be made into a lake for skating in a few hours, during freezing weather, by flooding it with water; and the freezing weather past, could be emptied again instantaneously, and the grass would be none the worse for submergence. In the exercise of our calling, we have several times formed bowling-greens in this manner, securing in one direction a supply of water, and in the other escape for it to an outfall. This plan admits of endless modifications. It can be adapted to undulating ground, provided there is somewhere a definite boundary of extent commensurate with the supply of water at command; and this boundary may be irregular, so as to blend with the natural undulations of the ground, or it may be made to form a succession of separate lakes for separate purposes, or to adapt a small supply to a

great space, provided the frost lasts long enough to allow of filling them all.

As respects the rights of the public to skate where they please, we do not pretend to offer an opinion. But we may ask this question: If bathing, boating, and fishing in this or that lake or river is illegal, is not skating on the same water an act of trespass? The reason that the London parks are dangerous to skaters, and sometimes equally dangerous and obnoxious to decent pedestrians, is that they are under no sort of government whatever. Had there been any kind of government existing, there would have been less loss of life than has occurred, and less disorder when life has not been endangered.

ROSES AND ROSES.—No. I.

I have just come home from a glorious walk beyond the alpine heights of Stamford Hill, laden with an *onus probandi*. One of our rosarians hereabout has thrust upon me the task of proving some assertions that are to be found in the "Rose Book," and unravelling some knots that exist nowhere but in this said rosarian's brain. I really did intend to say nothing about roses this season, but I am assured in the most solemn manner that three old subscribers will look exceedingly blue if their favourite subject is not "handled" frequently; and out of mere kindness I must, I suppose, "handle" the subject, and if I cannot say anything new, I must tell the old story, or any number of old stories, over again. I don't at all suppose there will be a word worth reading in the half-dozen rose papers I have solemnly resolved to let off before the spring bursts upon us. It is not possible, after having ransacked a subject like this, to discover anywhere a new vein: if it were possible, I know that O P Q, our particular friend who gives his mind to roses, as Chacornac gives his mind to the asteroids, would order half a dozen extra copies of this week's number if he knew that such twaddle as this were in preparation under such a heading as "Roses and Roses." O P Q lives in a perpetual dream. He dreams of winning gold cups, silver dinner services, cases of stuffed birds of paradise, infallible chronometers, and all sorts of elegant and useful things by exhibiting roses; and he has gone so far already as to have planted largely according to the directions in the "Rose Book," and in the atmosphere of delightful rosy dreams awaits the day of triumph. Now if I tell him he may expect a few thirds or fourths, that in a year or two he may aspire to a second, and if he still perseveres, remembering Bruce and the spider, and all the wise saws and modern instances that bear upon the development of the indomitable faculty, he may dare to hope for a first place, and to be the hero of a hundred battles. If I tell him all this as we walk together, making the hard ground ring under our awful tread, he may suddenly collapse, and lose a pleasure through aiming at more than is within his power. But O P Q may infer anything he pleases from what appears in print, and I can gently hint to him in this place that no one can expect to be an impromptu veteran; there must be toil before triumph—work before winning; the best workman never attempts to leap on to a roof; he is content to go up the ladder a step at a time; and so it must be for those who intend to mount the pinnacle of fame. The fact is, O P Q has made mistakes which are easily rectified, and the foundation mistake is that success in rose-growing is a question of money. Depend upon it money does not purchase a tenth part of the happiness it is reputed to do. I know a poor tailor who has a few rods of ground on which he grows to perfection the old double white rocket, and some fifty first-class pansies, and two or three dozen hollyhocks, and who dare not spend more than a shilling a week on gardening, and he derives from his little plot more real delight than many a would-be floral magnate who dribbles out gold upon his ground like water. This is not to discourage O P Q—not a bit of it: he is my most particular friend, and I do wish he had not made up his mind to win by a *coup de main* where there must first be an investment, next a regular siege, and lastly close fighting hand to hand against bravery, skill, and resources equal to any we can take into the field. I don't put faith in any man to accomplish great things in rose-growing unless he can grow them throughout. To buy and plant are very essential operations, and those who will do so much may make sure of roses in any quantity and at all seasons; they may sleep in the midst of rose leaves, and have the rose of health on the cheek to testify that Flora is a beneficent goddess. But to win at great shows is another

matter. The ambition is honourable; but the distinction is only to be achieved by first mastering the business in all its details, for those who already lead the way have done so, and we cannot hope to walk abreast of them, much less to outstrip them in the race, unless we bring to the encounter equal skill and equal knowledge, with all the moral qualities requisite to success, not the least being earnest love and unwavering determination.

O P Q put to me a question that he thought was new, but which is as old as rose-showing: Why is there usually such a distinction between the stands from first-class nurseries and stands from amateur cultivators? Generally speaking, there is a difference; but occasionally we see amateurs put up stands that eclipse in splendour the best that the trade have ever done. You may always consider an amateur a master of the whole business, if he can manage a first 48 or 24 in an open competition that is at all spirited; for mere buying and planting are not sufficient for that. As I am rather hard upon O P Q (for his good solely), I will endeavour to make amends by presenting him with a few suggestions. First I say, read the "Rose Book" again, and pay great attention to the chapters on propagating (nothing like leather). Those chapters were not written in the style of those gentlemen who do horticultural papers in the peat, loam, and sand style: they were worked out in detail during many years of experiment and practice first, and were not committed to paper until it seemed that there remained nothing more to discover or communicate. Success in showing turns very much upon skill in propagating; and hence it is that the nurseries, where propagating is the chief business, pour into the rose shows such wondrous stands of flowers. But about the particular question. The nurseries have an advantage: first, in quantity. An exhibitor with a sharp eye and an acre of roses in bloom, has two advantages to begin with, and ought to do some thing respectable in an exhibition. You just walk on, using the sharp eye, and from time to time you see a bouncer, and it is but a moment's work to off with his head and put it in a basket. Mere quantity is something. Ask Mr. Hedge, of Colchester, if quantity is of any consequence; and he may perhaps confess that he has plenty to cut at. Ask Mr. Perry, of Castle Bromwich, if amongst a thousand roses, all receiving good treatment, there is not a better chance of cutting a good twelve than amongst a hundred equally well treated. Another advantage the cultivator has over the mere possessor of roses is a predominance of youth amongst his plants. Your great-headed standards of twenty years of age may be glorious to look at from the windows, but what will they do for you on the day of exhibition? Not much, I trow. You see we are getting warm now, as the children say in the game of hot boiled beans and plenty of butter. "Youth is always beautiful," some poet has said (it matters not who). O P Q had better dabble in briers, manettis, and own roots, mastering for himself all the details of propagating, and he will get finer roses than by merely buying and planting. He will get used to roses, and roses will get used to him, and the two principal agents in a rose show, the exhibitor and the thing exhibited, will be place *en rapport*, as the French say, and we shall probably hear of both again. It is a fine thing for an exhibitor to have a plot of ground apart from the rosarium proper, and therein to follow the noble art as an amateur in the proper sense of the word, for to buy and plant is at best to be but a *dilettante*. In such a spot there should be always some sort of propagation in progress to transfer the new varieties from manetti to roots of their own, and to put a few of all the best roots, new and old, upon young briers every year. To obtain the finest possible rose that can be cut, that is the question. Now I think we shall come near to that accomplishment with free-growing sorts when we take the second or third bloom (sometimes the first) from a young brier rose worked early the previous season, and which has not been lifted since the bud was put on. Let O P Q lay this to heart. Rosarians of all ranks and degrees, what do you think of budding young briers with a view to allow them to remain undisturbed till three years old, cutting what you can from them in that time, and then making the stems into flower-sticks, and the tops into cuttings to put into frames in October? To do this in the flower garden, is to convert a drawing-room into a workshop. If the nursery appears to enjoy a *prestige* in the exhibition, let us have nurseries too, and cut from young plants, combining in the scheme quantity and youth. I trust that O P Q will find enough in this to think about for the present; I hope to address him again shortly.

S. H.

JOHN SCOTT, MERRIOTT NURSERIES, CREWKERNE, SOMERSET. *Catalogue of Vegetable, Flower, and Agricultural Seeds.*—Well arranged, comprehensive, and trustworthy.

HOOPER AND CO., CENTRAL AVENUE, COVENT GARDEN. *Spring Catalogue 1867.*—This is a very interesting work, full of information, with a few useful woodcuts; and in the several sections enumerates many subjects of special interest and value. The arrangement appears to be confused, and is certainly capable of improvement; in all other respects it is a first-class catalogue.

THE GOOSEBERRY TREE AND ITS TRAINING.

Quite a revolution has taken place within the last few years in the style of training fruit trees, especially standards. Perhaps it may have originated with the introduction of orchard-house and miniature trees. By some the system is considered to be very profitable, because you are enabled to grow a greater variety within the space formerly occupied by a less number, and the fruit they yield is much superior in size and flavour compared with the former practice. The idea of their introduction may have been first gathered from observing the methods of planting and training in our market gardens. Having in my boyhood been employed in a market garden, I have always felt a peculiar interest in watching their operations. In later years, uniformity of planting and training is much more closely practised there than in private gardens. That market gardeners should economize space is not surprising, for every square yard of land must contribute to the profit of the concern. The regularity which you observe in the growth of whole acres of fruit trees is to be attributed in some degree to the large quantities which are cultivated of one particular variety, and thus their habits being alike they present a very even surface. Yet with all these advantages, the management of them is entirely conducted on scientific principles. When residing in the county of Kent, I have witnessed large plots of the Warrington gooseberry so carefully pruned that one plant might be taken as a *fac-simile* of the whole. The knives they employ are specially made for the purpose. They are sheath knives, and much larger than those commonly used by gardeners. In private establishments where the extent of ground is limited, we cannot expect to realise the same uniform style throughout, because there are many difficulties to contend with, and which are decidedly opposed to such a practice, such as the variety of habits which abound even among plants belonging to the same class. The gooseberry is an example of this. Yet I am induced to think that we could do much by studying, and thus practising, some peculiar mode of training, and so seek to overcome the difficulties connected with the constitution of the various varieties.

My thoughts thus far have been suggested by a unique but small plantation of dwarf pyramid pear trees now under my charge. Growing beside them are some luxurious bushes of gooseberry trees. The object of their culture has been to obtain ripe fruit for dessert. They have been so trained that nearly all the lower portion of the bush must, by reason of the weight of the fruit, come in contact with the soil; and thus quantities, especially in showery weather, will be rendered unfit for table. Why not endeavour to save this fruit by training them into a somewhat pyramid shape by fixing stakes to each tree? It may be said it is not worth the trouble, or rather impossible, to adapt every variety to that style. Now I can prove from actual experience that it is not only beneficial to the tree, but profitable, by enabling it to produce a much larger quantity of good sound fruit. In my last situation I successfully adopted the above plan of training, and whoever saw the trees were delighted with the mode. I had upwards of a hundred trees tied to iron rods, many of which were 5 feet in height. Among them were a great many of the well-known Lancashire varieties, and several bushes of Warrington, which is one of the most useful in cultivation, alike for dessert as well as culinary purposes. Of course, in thus training them, a good deal of patience and perseverance is requisite in the commencement. In pruning, you must ensure a clear stem for some little distance, and thus give every encouragement to an upward growth. Selecting a vigorous leading shoot, it will be necessary to suspend the lower branches with tared string to the stake, as some sorts, in spite of your efforts, have a disposition to produce the growth of their shoots towards the earth. If those of our readers who are interested in the subject will try the system, I am satisfied they will as time progresses be delighted with the result.

JOHN F. M'ELROY.

T. SAMPSON, YEovil. *Catalogue of Flower, Vegetable, and Agricultural Seeds.*—A good local list, containing everything useful; and a good table of quantities for the guidance of purchasers.

DOWNIE, LAIRD, AND LAING, STANSTEAD PARK, FOREST HILL, LONDON, S.E.; AND FREDERICK STREET, EDINBURGH. *Catalogue of Flower, Vegetable, and Farm Seeds for 1867.* A very important book in respect of its selections and specialities, and admirably got up for reference and usefulness. We find in the list of potatoes those excellent varieties Rintoul's Early Don and Moffatt's Prolific. The selections are amongst the best we have seen.—*Descriptive Catalogue of Roses.* Comprehensive and truthful, and very judiciously restricted to classes and varieties that are really useful and in general demand.

LONDON SEED COMPANY. *General Price Current of Kitchen Garden, Flower, and Farm Seeds.*—A good businesslike list, equally adapted to gardeners and farmers. In the flower-seed department there are some very tempting offers. It is a curious thing that it is impossible to discover from this "Price Current" where the offices of the society are situated.

G. GIBBS AND CO., 25, DOWN STREET, PICCADILLY. *Catalogue of Kitchen Garden Seeds.* A large sheet list, with spaces for customers to fill in the quantities required, which saves all writing of orders.—*Catalogue of Agricultural Seeds.* In this, besides the subjects ordinarily in request, is a list of selected meadow, pasture, and lawn grasses—a class of plants on which Messrs. Gibbs have bestowed much attention, to the immense advantage of the community.

NOTE ON BORDER-HEATING.

BY THE REV. W. KINGSLEY.

(From the Journal of the Royal Horticultural Society.)

The border which I have the means of heating is about 120 feet long and 10 feet wide, and is at the foot of a south wall 12 feet high, with a cross wall at each end. Four pipes run the entire length, and are in the midst of a mass of drain-tiles, which are at right angles to these hot-water pipes, and lie in lines sloping upwards towards the wall, with rise enough to secure the flow of the water, and the circulation of the hot air; upon

the drain-tiles there is a layer of coke. The result gives me a temperature about that of a very gentle hotbed. I do not think I should construct the bed in the same way again; but I had been doing a good deal of draining, and the defective tiles were good enough for this purpose. My fruit-trees are in pots, some as large as 2 feet across, but most of them 15 inches. The pots stand upon the coke, or very little above it. In winter they are covered with earth and dry litter, so as to keep the frost off completely; but in the mild weather they are little more than half buried, and in the heat of summer are raised to the surface to let the sun give them as much heat as possible, and at the same time to allow the roots during the summer months to pass out of the bottoms of the pots into the ground.

The way in which I have applied the heat is, as far as I can, to encourage the growth of roots in winter, and to give a temperature to them when the fruit is setting above what we get from the sun in this climate; and then again, when the heat begins to fail in early autumn, to give warmth to ripen the wood and get the trees put to rest early, by their having heat and no water. Perhaps it will be best to state how the trees are heated throughout one year. During the sharp frosts of winter the hot water is kept going night and day, and I have heat enough to thaw any snow that falls, but I do not raise the temperature of the ground so high as this, but only enough to prevent the roots being so much checked in their growth as to destroy the young spongioles. Whenever the weather is mild the fire is not lighted; and by the end of February there is rarely any occasion for artificial heat. As soon, however, as the trees are in full blossom, the fire is again lighted, and the heat steadily increased, and kept up till the sun warms the ground thoroughly. At this period the fire is lighted early in the morning, and allowed to go out at night, and so gradually till artificial heat ceases, about the middle of June, or later if the season be cold; and if a few cold days come, I give heat again during the day. During the blossoming season the trees have a wide piece of netting over them. The trees now will have got a very great advance upon those in the open ground so far as the ripening of the fruit is concerned, but they do not open their blossoms more than a very few days before them.

Then again about the end of August I give heat during the day, and, according to the nature of the fruit give water or withhold it, as I would encourage growth or ripen the wood. In the latter case it is necessary to cover the pots with slates or wood, to keep the rain off. My rule is to withhold water and give heat as soon as ever the fruit is ripe. When the terminal buds are fully developed, the pots are lifted and the protruding roots cut off, the soil taken out half-way down, and the roots so far cut within a few inches of the stem; fresh soil is put in, a little water given to the tree, which is placed on the hot border again for about a couple of weeks, and then kept dry till the leaves fall, and for some time after. The root-pruning is going on from the end of September to the end of October (I believe it should always be performed before the leaves fall); and by giving water and heat the trees do not flag for more than a day, and heal their wounds at once. No doubt much has to be learned here, and it will require many seasons to find out the best treatment. My object is to get the trees to cast their leaves very soon after the wood is mature, and to stop the long herbaceous growth that our damp autumns produce. I need hardly mention that close summer pinching is practised, so that very little winter pruning is needed. The dry heat soon sends the leaves off, and a long rest is given to the trees during the autumn. Some are placed under glass to ripen their fruit; and all would be, if I had sufficient extent of it; for as the trees are merely resting, a small space accommodates a great number, as they may be packed close together, and, the pots being dry, no mildew need be feared, as they have at this time plenty of air. Finally, as soon as the rains of autumn are over, and the cold weather sets in, the hardy trees are again put into the hot border.

As may be expected, the flavour of the fruit is first-rate, and the additional length given to our summers allows many kinds to come to perfection that otherwise we cannot ripen. A month or six weeks is certainly thus added. We have plenty of light from our long days in summer; but excepting for July and part of August we have no heat in the ground, and during our long cold and wet autumns the rootlets of our trees rot and die, and they have to grow again before the trees have strength to swell their fruit. I tried three trees of *Beurré Superfin* last year, all grafted at the same time and equal in vigour—one in the open ground, one in the orchard-house, and one with root heat and no glass. The pears from the open border were about the size of walnuts, those from the orchard-house fair-sized and good, but those from the hot border were larger and finer than I have ever seen in the south of England; and it must be remembered that the season was one especially favourable for the open border, the trees in which had not been disturbed for three years, and were kept well mulched during the hot weather.

I first began the system of bottom-heat by plunging strawberry plants

in an open hotbed, and planting them out after giving them a rest in the autumn; and the result induced me to try the plan on a larger scale with very various kinds of fruit. One very useful application of the hot border is for grafting young trees. The stocks potted early in the autumn, and treated like the other trees during the autumn and winter and early spring, are quite vigorous enough then for grafting, and they push strongly and get no checks, and so there is no trouble in keeping back the scions till the stocks are ready.

Last year I put a row of potatoes just over one of the hot-water pipes, at the same time that the ordinary crop was planted. Some time afterwards my man (who is not learned in gardening, though thoroughly trustworthy and interested in his work) came to me and said, "The tatties on the hot pipes are not thriving like those in the ground." I asked him what made him think so; and then it came out that he was judging by the tops. However, in a few days more the ground over those in heat swelled and broke up like molehills, and we had in the beginning of June the best potatoes I have had at any time since I came here six years ago.

I am now making preparations for giving bottom-heat with glass overhead, and I shall be very glad to work out any systematic experiments on the use of heat without glass, glass without heat, and heat and glass united; but I am sure that unless our experiments are based upon some principle to begin with, they will never be of value for making correct inductions; and so I shall be glad to give some time to experiments of a scientific kind in order to obtain results that, as an individual, I should never live long enough to see, but which by the united efforts of many may be arrived at in a very few seasons. So please do not think that in the account I am giving you I suppose my system to be anything more than an experiment, or that I should consider it otherwise than a hasty induction to declare from it that the principles which for the sake of clearness I have stated, are in anywise proved to be correct.

South Kilvington, Thirsk.

HEAT.

One might ask the question, "What is heat?" but it would be difficult even for the philosopher to make reply. Whatever we see, feel, taste, and smell is in some degree or other filled with it, and the properties of organic substances are in great part produced by heat. We see and hear of the power of heat always and every day wherever we go. Whence came this powerful and wonderful principle that connects together all the phenomena of the material world?—the grand foundation which furnishes the earth with a regular supply, and makes it capable of supporting animal and vegetable life? If we torture or imprison it, or do what we may with it, its power and effect remain the same—unchanged and unchangeable. We devise means to extort heat from water, in order that we may make ice. We also force it into water to warm our apartments, and in our pineries, vinerias, and stoves, to enjoy the productions and growth of tropical luxuries. Heat gives wings to the ships, and bids defiance in a great measure to the waves of the sea, for even if the wind is contrary, steam is usually its master. It is also as horses to the locomotive, and enables it to outstrip the flight of the swiftest bird in the air. Heat is every way present, and every material in existence contains it. When we sleep at night, we require a due regulation of it, and by its influence our food contains its nutritious and enriching qualities; and without its presence our fruit and grain would be as tasteless and insipid as the roots, branches, leaves, and grass that held and protected them.

In health, heat is our mainstay and support, and in sickness it is our physician and medicine. Under a high degree of heat we languish; in severe weather, without it we shiver. If heat is allowed to accumulate around us in undue quantities, we burn with fever; and if taken from us too quickly, it leaves behind many maladies to testify to its loss.

Heat is a good servant, and lends its power and influence always and at all times, ever ready to do good service for man's enjoyment and welfare. We have conductors and non-conductors of heat, and by their aid we keep ourselves warm in winter and cold in summer with the same sort of coverings. Woollens or flannels are among the worst conductors, cotton and linen the next. All these three kinds of wearing apparel may have the same temperature of heat, yet to the touch one may feel warmer than the other. Metal is the coldest material we have in the house, stone next, and wood still less, and woollen feels the warmest of the whole. Good conductors have a lower temperature than our body, and thus feel cold when we handle them. Other things with a higher temperature than we possess feel hot. So it is with this most wonderful thing heat, and the phenomena connected with it. The earth possesses a certain amount of heat, but the sun must be regarded as the principal source of it. Heat may be produced by different ways and means: a nail may be made red-hot by the application of a hammer; by the friction of two pieces of wood, by boring or turning of metals, by rapid or powerful compression, and by the process of combustion. Decomposition of food in the human body is noticed as an abundant source of heat. I asked the question at the commencement of this article, What is heat? Well, what is it still, after so much is said concerning it and its production? By the term "heat" we mean sensation. If we touch fire, or anything hotter than our flesh, we call it hot. Fire is the cause of burning. A hot fire, a hot place, a hot house, hot weather,—these are terms indicative of the presence in this or that place of more heat than is congenial to our feelings. Heat raises the temperature in proportion as it increases, and the philosophical instrument called a thermometer tells us the number of degrees of heat. The force with which the particles of a body cohere is entirely dependent upon heat. The existing adhesive force decreases proportionately to the increase of temperature. Burning gas produces heat and raises temperature while affording illumination. Some small greenhouses are heated with coal-gas. Heat has been described as an extremely *subtle fluid* or *molecular motion* of matter. Whatever it may be, it must be regarded as pervading all space, entering into combination with other bodies, and producing wonderful effects of expansion, fluidity, ebullition, and evaporation. Without heat, nature itself would be lifeless and inanimate; and the recent frost has suggested to us that as water, the emblem of fluidity and mobility, becomes as hard as rock when a certain amount of its latent heat is abstracted from it by the atmosphere, so if its heat were to be all radiated from the earth the whole mass must become a crystal, and life would cease utterly upon its present life-covered surface.

A. D. ALLASON.

CRYSTAL PALACE.—It is not improbable that in the changes consequent on the destruction of the tropical department at the Crystal Palace a spacious concert-room will be built on the site of the magnificent courts beyond the screen, and the Handel orchestra removed thereto from the centre transept. Such a scheme is under consideration.

KITCHEN GARDEN SOILS AND THEIR MANAGEMENT.

LIGHT, DRY, SANDY SOILS.

One of the worst soils that a gardener has to contend with in the production of fine vegetables is a light, open, porous surface resting on gravel. These soils may be described as of a peaty nature, as they more generally abound on spots that have been at some time reclaimed from adjacent open waters, in which both hog-earth and peat are often found in any quantity. Such is the case in some of the residences that encircle Blackheath, and also in some of those that skirt a portion of Wimbledon Common; so that we see when they do occur, they are only made up of the same nature as a portion of the surrounding land, and consequently are ill adapted for vegetable culture, and it is not often that the right measures are adopted to increase their stability. Very generally there are not more than ten to twelve inches of surface soil, and this too often of that light open texture, that it may be said that it has not the power of retaining one-half of the sustenance that vegetable life requires (even when it is liberally supplied) because the first few hours' rain, after a dressing of manure has been given, washes down into the gravel below all the nutriment that the manure contains, and which a soil of a more calcareous nature would retain, to the evident benefit of the crops.

I am aware that much can be done by good management to make its character more retentive, and consequently increase its fertility, but to improve the staple of the whole requires expensive measures in many places. The chief secret in management in the first instance is to avoid deep trenching, for where there is only about twelve inches of soil suitable for cultivation, it can do no good to loosen up a bed of gravel beneath it; in fact, it will do harm, as it will be the means of allowing greater facility for the water to get away out of the reach of the roots of the plants, which must be prevented as much as possible in this case, as having only such a limited space to ramify in, they require too often more moisture than these kinds of soil have the means to retain. The aim of the cultivator, therefore, must be to retain so much moisture in the soil as he can during the summer months, and not make channels for its escape out of the reach of the roots of plants, that they may have the full benefit of every summer shower, and the gardener the satisfaction of seeing two or three days after that the supply of moisture is not quite exhausted.

With the case of fruit trees, and some permanent crops, as asparagus and rhubarb plantations, it may be desirable to specially prepare these spots by taking out the gravel and supplying its place with a better and a more suitable soil: but only in such cases would I advise the subsoil to be loosened up more than two or three inches, unless a portion of it could be removed, and its place supplied with better soil. This may be done more often than it is when lawns and gardens are first made, for I have seen good soil used for making lawns that would have been a permanent benefit to the kitchen garden, had it been removed there, and the worst soil from the kitchen garden made to do the same duty on the lawn, which it would with proper management. But where measures have been neglected to improve it in the first instance, the gardener will have no difficulty in doing so, provided he has the means. But here is the difficulty, for, as I have before stated, at this stage it requires expensive measures to do it effectually, for nothing short of a good coat of loam from six to eight inches thick will make a good job of it. But once given it such a dressing, and it will increase in fertility for years afterwards. Of course a less quantity would have a corresponding effect, but anything less than six inches will waste away in a few years, when a second application would be required to maintain the character of the staple that was given it when first applied. In choosing loam for this purpose, I would prefer it to be rather heavy in its nature, as a sandy loam would not do the same amount of good as that of a closer and heavier character.

The next best thing to improve such a soil would be two or three inches of clay strewn all over every vacant spot in autumn. This by being fully exposed to frost and all other influences of the elements, would by early spring so crumble to pieces, that if carefully forked in, it would get well incorporated with the natural soil; and if the same quantity was applied for two or three years successively, it would do a vast amount of good, by enabling the soil to retain more moisture, and consequently more sustenance for the crops to feed upon.

Chalk in a small state may be used advantageously in small quantities, but its chief benefit would result from its being of a cooler nature than the natural soil, and it would so prove highly beneficial in the hot summer months. But anything may be applied that will assist the staple to retain moisture, and reduce its burning character. But anything that will tend to make it more porous should be avoided; even very long dung should not be put into the soil unless it be early in the winter months, that it may get thoroughly decomposed before spring.

In closing, I may remark these kinds of soils are generally the earliest, as being so naturally well drained they are the warmest, but the quality which ensures their reputation for earliness is, later in the summer, a great enemy in preventing the satisfactory maturation of any succulent crop as compared to a soil of a colder nature. J. C. CLARKE.

THE FROST BROKE UP ON TUESDAY LAST, agreeably to the anticipations expressed in our note on the weather last week. About midday the wind veered from E. to nearly due S., and soon after settled in the usual manner at S.W., and after a fall of sleet, rain followed, and the temperature rose about 25° in the course of about six hours. It begins to appear that the recent frost tried vegetation as severely, or nearly so, as that of 1860-61. It is certain that Chinese and Japanese trees and shrubs in our gardens have been considerably injured. We should be glad if our readers will contribute information on this subject as opportunities occur for ascertaining the extent of the injury done. Reports from districts far apart, and variously situated as to geological formation and relative shelter or exposure, will be of lasting value, for the frost of 1867 will undoubtedly serve as an extreme test of the hardiness of plants, as well as of the possibilities of the climate of Britain.

GEELONG AS A GRAPE-GROWING DISTRICT.—Nearly one quarter of the area under vine culture within the colony is within the immediate vicinity of Geelong; and of the superiority of the Geelong grapes for wine-making purposes some notion may be conceived from the fact that of 110,000 gallons of wine made during one year within Victoria, nearly 50,000 gallons were made in this district.

When is literary work like smoke? When it comes in volumes.

ON LAYING DOWN LAND TO GRASS.

I have adopted a plan which with me has been successful, and I think would be so generally on soils of a similar character to mine, which is a clay, interspersed more or less with round stones, on the formation of the variegated marl. The fields on which the trial has been made had been prepared the previous year by cleaning thoroughly and manuring heavily, for Mangel or Swedes. In the spring, at the usual time, I have sown, with the corn crop, a mixture intended to remain down two years, consisting of cow-grass, common white clover, a few pounds of Alsike clover, Italian rye-grass, and sometimes a very small proportion of Timothy grass. The grass seeds are usually sown a few days after the corn, in order to secure a fixed tilth, and great care is taken that the land is in a proper state—neither too wet nor too dry. My first year's seeds are commonly mown, and are, as a rule, a more than usually abundant crop. The second year I generally find that the yield of herbage is nearly, if not quite, equal to the first. I ought to have stated that, after mowing the first year's crop, I generally pasture the after-growth with sheep, which are supplied with cake or corn. I continue this system during the following years, usually contriving that the field in question shall be pastured during some portion of the year by either sheep or calves which have a daily supply of artificial food. In this manner I have been induced to leave fields down year after year, because the supply of herbage which they yielded was so abundant that they were more profitable in this state than they would have been under a corn crop. Of course I do not wish to draw a general inference from my limited trials; but in this district, or in others which have a similar soil and climate, I should feel no hesitation in practising it on an extended scale. It is a great recommendation that the yield of herbage is so considerable during the first few years; and according to my observation, the more permanent grasses indigenous to the district gradually introduce themselves into the vacant spaces left by the dying out of the biennial species. Of course this process is greatly accelerated by putting on a compost in the spring, and sowing hay or mixed grass seeds among it. I have at this moment a field divided into two equal portions, half of which was laid down according to the plan I have described, and the other half with permanent grass seed of the most expensive description. Wishing to give this portion every advantage, it was limed previous to the corn and grass crop being sown. Its high condition was proved by its yielding, in spite of exceptionally thin seeding, a very heavy crop of barley. The first year's mow of grass was, however, miserable; and the subsequent herbage, notwithstanding repeated manurings, has continued most scanty. The other portion of the field is a complete contrast to this, presenting in the fourth year after it was laid down every promise of becoming a valuable permanent pasture. Most persons, in walking over this field, imagine that the facts are the very reverse of what is actually the case, namely, that the worst portion was sown with temporary grasses which have died out, and that the other was sown with permanent grass seeds. A friend of mine in this neighbourhood laid down a field without a corn crop some years ago, with permanent grasses procured from an eminent seedsman. Although neither trouble nor expense had been spared from first to last, the result was so unprofitable that, after waiting in vain during seven or eight years for improvement, he has broken the field up. During the last year or two he has adopted my plan, with every prospect of success. On a large proportion of strong lands, the practice of keeping clover and rye-grass down for two years presents many advantages. It is a saving of expense both in seed and labour; it rests the land, and improves its condition, while it allows of a rotation during which clover occurs at longer intervals. If the relative prices of mutton, wool, and corn, which have prevailed during many years, continue to hold, an acre of good sheep pasture pays better than an acre of corn. Whether or not it is advisable to extend the time during which land is allowed to remain in grass will of course depend upon many circumstances which will occur in different cases. But it is important to know that the occupier has it in his power to do this without incurring loss. I consider the Alsike clover quite essential to the success of this plan. In selecting the proportion of cow-grass and Italian rye-grass, the farmer will, of course, be guided by circumstances. Where the clovers are certain to stand, the proportion of rye-grass may be reduced very low.—MR. WILLOUGHBY WOOD, in *Bell's Weekly Messenger*.

CATALOGUES.

F. AND A. SMITH, WEST DULWICH. *Retail Catalogue of New and Choice Plants*.—In this are comprised all Messrs. Smith's novelties for 1867. In the lists of Cinerarias, Geraniums, Fuchsias, Azaleas, and Pelargoniums, are some valuable new varieties.

W. CUTBUSH AND SON, HIGHGATE, LONDON, N. *Catalogue of Vegetable, Flower, and Farm Seeds for 1867*.—A capital list, neither overladen with varieties, nor deficient of anything really good. A selection of flower seeds, and Gladioli, Anemone, and Ranunculus bulbs, is added. Amongst the novelties is Cutbush's variety of *Lilium auratum*, the flower of which has bands of red, in place of the usual bands of yellow.

WHEELER AND SONS, GLOUCESTER. *Little Book, or Select Seed List for 1867*.—A pretty and amusing trade list, containing many specialities, and good selections of standard subjects. The cultural notes are brief, but quite to the purpose; and there is a good paper on pasture grasses.

RICHARD DEAN, EALING, LONDON, W. *Catalogue of New and Choice Vegetable and Flower Seeds*.—A very interesting list, containing perhaps more novelties than cautious people will care to invest in, and too many quotations of a class suggestive of R. D.'s obsequious anxiety to propitiate an influence. Pity that some useful information should be mixed with what looks like toadyism; but every one to his taste.

H. CANNELL, FUCHSIA NURSERY, STATION ROAD, WOOLWICH. *Floral Guide for 1867*.—This is a capital little book, for which Mr. Cannell has the courage to charge 3d., a much more sensible proceeding than giving it away, and quite as likely to bring trade as if sent about free and broadcast. It contains descriptive lists of Fuchsias, Verbenas, Petunias, Tropaeolums, &c., &c., with discriminating criticisms on their respective merits, and some racy bits of information for those who can be taught by a merry word as well as by a prosy essay.

There is now in the aviary at Knoulesley (says the *Liverpool Albion*) a turtle-dove which hatched two young ones, in a tree in the open ground, on Christmas Day morning. The same pair of doves hatched on Christmas Day last year in the same tree, and on New Year's Day the year before.

ODDS AND ENDS.

TALLIES.

I once knew a lady, blessed with a large family, who, in reply to the urgent solicitations, at dinner-time, of her numerous offspring for more copious supplies of the succulent juices of pie or joint, was accustomed to remark, "Well, my dears, you can't have it *all gravy!*" It always struck me that this axiom was so applicable to almost every condition and occurrence of daily life as to deserve to rank by the side of Franklin's celebrated phrase of "Paying too dear for one's whistle." In gardening especially, it is impossible to have it *all gravy*. There are insect pests, animal pests, atmospheric pests, and all sorts of natural pests and discouragements; but to amateurs, at least, there is not a greater nuisance than the artificial one of "tallies." More ingenuity in a small way has been expended on this subject than would suffice to construct a reasonable code of laws for a nation, yet with utterly unsatisfactory results. Our esteemed Editor, with his usual acumen, has devised a plan for meeting his own purposes. He uses a four-cornered wedge-shaped piece of wood about the size of an ordinary rolling-pin. This is painted white, and contains on one side, in large letters, the name of the variety; the other sides are devoted to chronicling the date of its introduction, and any other remarks as to its cultivation, habits, and the like desirable to be preserved. These are thrust into the ground by the side of the plant. Now this may do very well for an experimental garden, but is totally beyond the appliances and requirements of ordinary amateurs; besides it requires great care and watchfulness to ensure their being placed correctly, during alterations and removals. Zinc tallies are patronized by many, but however enduring, they are very indistinct at a distance, and are apt to come off the plants from the corroding of the wire by which they are attached. Wood and parchment labels soon rot and decay. I shall now proceed to detail a method I myself am adopting to overcome the difficulties of the tally question, with strong hope of success. For the sake of brevity and precision, I shall give the method in the form of a recipe after the manner of Monsieur Soyer, or the venerable and respected Mrs. Glasse.

First get some spoiled blind laths (such as are used for Venetian blinds), before they are painted: they are cheap enough! Take a strong sharp knife and flat ruler, and cut them into strips the size you require: they will cut as easily and pleasantly as bread and butter. Then with a thick *indelible* garden pencil write upon the strips the name of the plant, and the first step is completed. Next, procure a few pennyworth of *hard white varnish*, with which coat the tallies two or three times as they dry. Bore a hole with a small awl at the end in each, for the insertion of some thin galvanized wire, to fasten on the tallies, and I venture to predict a tally will be produced of an enduring constitution, capable of sustaining any amount of winter and wet weather. A thin hard cord of the texture of whipcord, thoroughly *tarred*, would perhaps be the best material to tie on labels with, and the ultimate saving of labour and confusion would amply repay the trouble of its preparation. The above manufacture would form an interesting and useful occupation during dull evenings for the young ladies and gentlemen of the family, provided they did not cut their fingers too often through too rash use of the knife.

THE FROST AND THE ROSES.

"Then Winter came: the wind was his whip;
One choppy finger was on his lip;
He had torn the cataracts from the hills,
And they clanked at his girdle like manacles."

We have lately had a tolerably sharp visit from the above-named formidable potentate, and he does not seem in any hurry to take his departure. "I tell you what, my friend," said an enthusiastic rosarian to me the other day, "our roses will catch it as badly as in 1860." I fear this is too true: they were so green and growthy up to the very day that King Frost set his iron grasp upon them, that they were as utterly unprepared to resist it as a man clad in a dress coat, white vest, nankeen trousers, and patent leather boots is to clear away the snow from the housetops. Happy the farsighted and cautious individual who prepared for emergencies by coating up his tender favourites with coats of mulching and comforters of haybands. I frankly confess myself to have been caught napping. I shudder to look at my Mareschal Niels, and dare not even think about Madame Falcot and other delicate fairies of our summer affections. One good result, however, will accrue from our losses, be they what they may, which is that the constitution of our newer favourites will undergo such a trial as they have never experienced before. If Mareschal Niel, in particular, comes forth from the ordeal triumphantly, it will enhance the value of the variety to the highest pinnacle of merit. For protecting tender roses on their own roots, nothing is better than a few handfuls of charcoal scattered round the collar to dissipate damp, over which should be laid on 6 or 8 inches of cocoa-nut refuse or flaky manure. For the same

kinds on the brier, nothing is superior to a good wrapper of haybands about the bud and lower branches, leaving the long shoots to be killed back or not as it may happen: there will be plenty of new wood formed from the protected parts.

From the shivering pinched-up appearance of aucubas, and other choice evergreens—all but hollies, whose crisp leathery leaves appear to defy any amount of frost—it is to be feared there will be no little havoc among tender winter shrubs, as well as among the roses, should the present severe weather not soon break up.

PERMANENT EDGINGS OF VARIEGATED PLANTS.

Is it not possible to devise some improvement in the method of constructing variegated edgings or borders to beds, so that they may become permanent articles of garden furniture? The various kinds of white and yellow variegated geraniums are pretty enough while they last, but they are a constant source of trouble and perplexity and expense to the gardening public in their annual propagation, preservation, and renewal. If the same neutral greys could be produced in hardy subjects that would stand the winter, it would afford us something to look at in that bare and dreary season of the beds, and form a basis as well for spring as summer planting. There are some of the varieties of striped-leaved periwinkles, ivies, the variegated euonymus, &c., that would rival any border or ribbon of Attraction or Golden Chain. I throw this out for the consideration of our talented Editor, or the able O'Shane.

WINTER FLOWERS FOR SMALL CULTIVATORS.

From December to January is the most trying period in the whole year to the amateur florist who wishes to keep the shelves of his conservatory or greenhouse interesting, or to furnish plants or flowers for the decoration of the hall, the drawing-room, or the dining-table. Late fuchsias and chrysanthemums have become utterly scrubby and unpresentable; camellias are scarce in small establishments; scarlet geraniums, if any puny specimens are left, have blossoms like the shreds of red list whereby trees are nailed to the walls; our little bulbous pets are scarcely forward enough for decorative purposes,—so that the pretty Quakerish primulas are almost the only subjects to be relied upon for floral enlivenment of our winter-bound habitations. In this dilemma, foliage plants are too much lost sight of, although there is as much real interest, and beauty in elegance and peculiarity of form, as there is in brightness and variety of colour. Succulents also, particularly of the cactus and sempervivum tribes, might perform a much more important part as ornaments than they do. The various kinds of the melocacti, with their grotesque and abnormal configurations, would be objects suggestive of many a quip and joke congenial to the mirthful season of Christmas; nay, I have some serious thoughts of appearing with one attached to my button-hole, in lieu of a camellia or rosebud, at the next party I go to, just by way of peculiar experiment.

With a view to see what might be accomplished in winter flowers, I paid a visit a few days ago to the show-house of my friend Mr. John Fraser, Lea Bridge Road Nurseries, making sure if anything noteworthy was to be found it would be met with there. When we find a sparse number of subjects—that is, suitable for small cultivators at an establishment like this—it only exhibits the truth of the assertion with which this paper commenced, and renders the few suitable subjects we can discover of the greatest value.

The first I noted down was a foliage plant, *Centaurea argentea*, admirably adapted for a table centrepiece, being of a branching, fern-like contour, of the colour of *Cineraria maritima*: *Centaurea gynnocarpa* closely resembles it. The next was the variegated *Euonymus*, tolerably hardy, and which, if kept low out of doors, would I should say make a pretty edging. Then *Yucca filamentosa*, its sword-like leaves beautifully striped with white, a splendid thing for a hall or dinner-table as the central point of decoration, to be surrounded with forced hyacinths, tulips, or primulas. Then there were *Chorozemas*, *Leschenaultias*, *Correas*, even *Aphelexes*, all of them capable of being used as foliage plants till their flowering period arrives. *Araucaria excelsa* is a fine decorative plant for indoors, if not grown too large—something like those small firs used for that most charming arboreal production, in youthful eyes, the "Christmas tree." Several kinds of *Ericas* are applicable as ornamental plants, even before they flower, from the diversity and delicacy of their conformation; and with them may be joined the old favourites as they come into season, the *Acacias*, *Coronillas*, *Cytisuses*, *Deutzias*, and *Daphnes*. I remarked also an excellent nearly hardy, bushy plant, suited for a cool greenhouse and for indoor ornament, named *Thuja Donneana*, grown like a little compact tree, the foliage resembling some rich *Lycopodium*. Of course there were many other subjects of a more important character than those I have noticed, but such are not for the minnows of horticulture, for whom I have just noted down the above few subjects as likely to supply a want during a special but brief period of the year, and which are moreover inexpensive and easily managed.

London Road.

W. D. PRIOR.

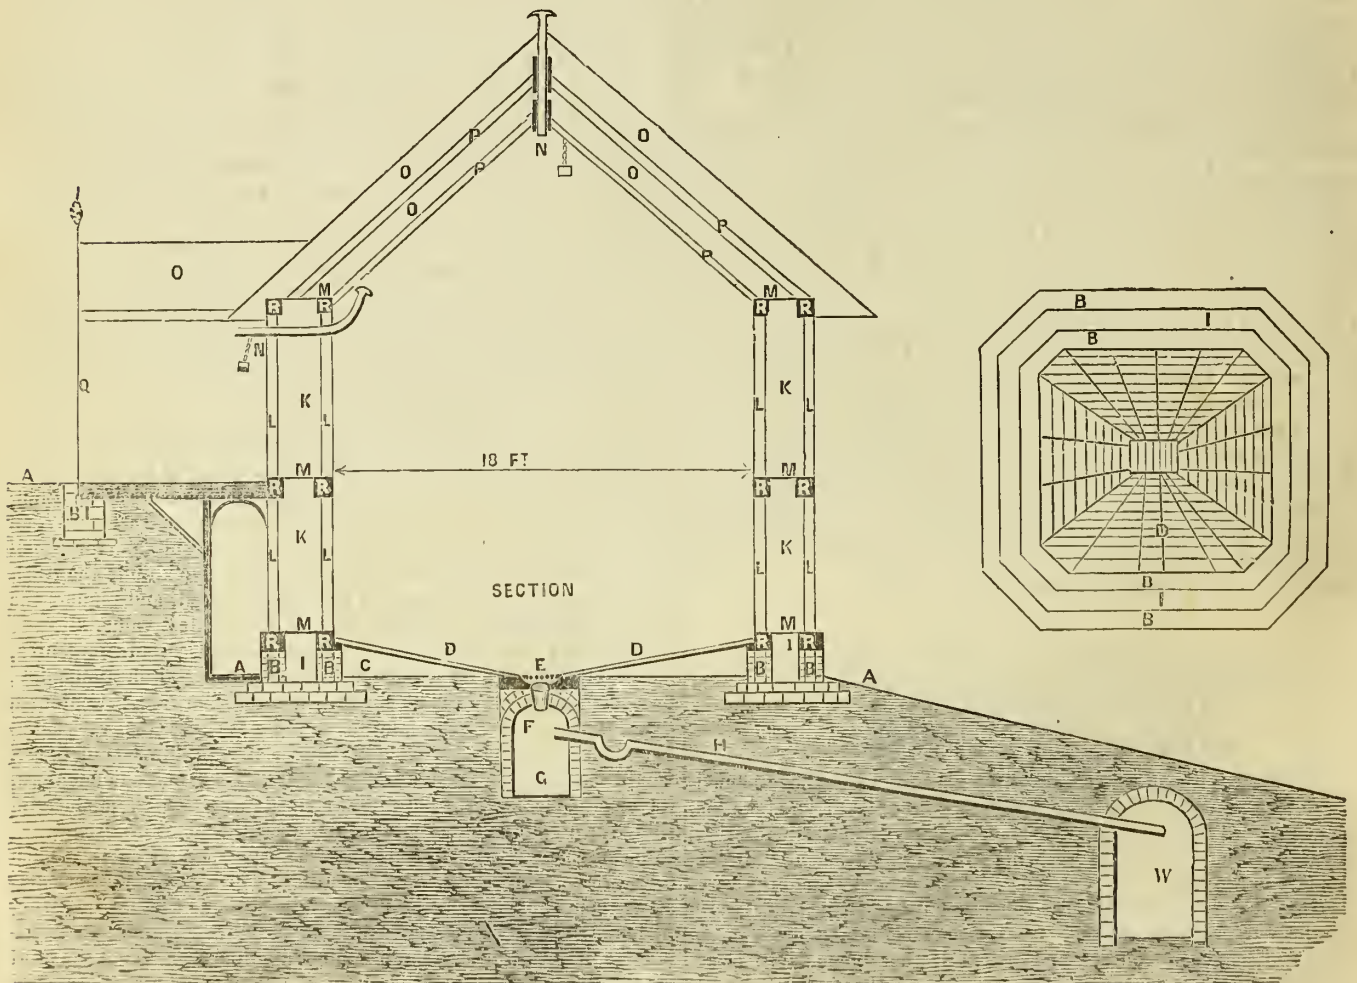

ICE-HOUSE AT THE SEAT OF THE EARL OF CLARENDON, NEAR WATFORD.

In my notes from this place made in the summer of last year, I briefly referred to the ice-house of which a sectional figure is subjoined; and I have great satisfaction in laying before your readers the following details respecting it, because in its construction there are embodied some new principles that have proved eminently successful in securing the conditions essential for the keeping of ice. My satisfaction is the greater because these new ideas originated in the mind of my worthy friend Mr. J. Myers, the able gardener there, whose ability on a previous occasion it was my pleasing duty to speak of in no measured terms of praise at the time of my first visit to this place, and I now refer again to the subject of the ice-house as seen at that time, and of its condition on a more recent visit.

The position of the house is at the foot of a north bank well shaded by large trees. In the first place, all the earth for the size and depth of the house and foundations was excavated and thrown up to form the entrance or roadway to the porch, as shown on ground-line at letter A. The house is 18 feet wide, with 1½ feet of brickwork above-ground, and from the brickwork to the angle of roof is 14 feet. For the better understanding of it, we will now take the ground-plan for our consideration. It will be seen that in shape it is a square with the sharp angles cut off. Casting the eye back for a moment to the plan of the house, at bottom we have letter G; this is a dry well, the bottom of which is chalk. F, bell trap; and E is an iron grating 2 feet square, covered with 4 inches of birch faggots. At D on ground plan, strong rough oak slabs are nailed to stout rough oak joists at B B; on each side are brick walls. At I is a space between, which is filled up with einder-ashes. Then again at B B are the outer foundation walls, the space between these too

walls being filled up as just stated. We have now to go back to the other portion of the plan. If we first trace out the ground-line at letters A A A, we shall better understand the details. Considerably below the level of the bottom of the house, and under the ground-line, is a dry well (W), 12 feet from the front of the house; the dimensions of this well are 4 feet by 6 feet, down into the chalk. The object of this well is to act as the receptacle for the overflow of water, should any quantity accumulate in the well beneath the house at G. It is conducted by pipes from G to W, as shown at H. This is an admirable feature, as there is a perfect system of drainage secured to the house, without the possibility of air being communicated to it, as a current of air at this point would be highly injurious to keeping ice. The spaces at C C, beneath the floor, previously referred to on the ground-plan, are filled up with sawdust to prevent the heat from ascending from the earth. The letters B B on each side show the brick foundations, and I I the space between the foundation walls, as I explained when referring to the ground-plan.

This now brings me to the building as it stands above-ground. The most remarkable feature here is in the fact that it is constructed solely of non-conducting materials, to which, combined with the excellent arrangements which I have already explained, may be attributed the success that has attended the efforts of my friend to secure a perfect ice-keeping house. The internal and external walls—as I shall for convenience sake call them—are hollow; but they are actually built of timber—that is to say, there are two rows of uprights at 15 inches apart all round. These uprights rest upon stout plates, which plates are built on the brick foundations. To each side of these uprights stout boards are nailed: inside walls, 1½-inch oak boarding; outside, 1-inch yellow battens; and the spaces

ICE HOUSE AT "THE GROVE," NEAR WATFORD.

REFERENCES TO PLAN.

- A A, Ground level. B B B B, Brick walls.
- B L, Brick foundation to front of porch.
- C, Sawdust beneath floor to prevent heat ascending from the earth.
- D D, Strong rough oak slabs nailed on strong rough oak joists.
- E, Grating 2 feet square covered with 4 inches of birch faggots.
- F, Bell trap. G, Dry well, bottom of which is chalk.
- H, Four-inch tile drain.
- W, Dry well, 12 feet from front of ice-house; dimensions, 4 feet by 6 feet, down into chalk.
- I I, Coal ashes between brick walls. K K K K, Best wheaten straw.
- L L L L, Sawdust between uprights, which are 15 inches apart all round.
- M M M M M M, Strong ties dovetailed into sills: middle and top plates at equal distances all round.
- N N, 1½-inch gas pipes for ventilation, with caps suspended, for screwing on or off at pleasure. O O O O, Thatch.
- P P P P, Rafters. Q, Porch. R R R R R R, Sill middle and top plates.

SUBSTANCE OF WOODWORK.

	Inches.	Inches.
Sills	8	5
Middle and top plates	7	4
Centre uprights	7	4
Intermediate Studs	6	2½
Outside angle posts	7	7
Inside angle posts	5	6
Roof rafters	5	2½

Inside walls, 1½-inch oak boarding; outside walls, 1-inch yellow battens. All the woodwork except the battens is good oak, two years cut.

In forming the foundation all the earth removed was thrown to the upper side, to raise still higher the embankment which naturally was there, and to form a roadway for carting, also foundation for porch.

left open, as shown at L L L L, are filled up with sawdust, while the hollow space between the two walls is filled up with the best wheat straw that can be had, and trod down as close as four men can get it. M M M M are strong ties dovetailed into sills; middle and top plates all round, at equal distances. R R R R R R sill; middle and top plates.

We now come to the roof, and it will be best understood when I say there is a double roof. P P P P are the rafters, and O O O O the thatch; but if my memory serves me correctly, there is an open space of confined air between the two roofs. But if I should be in error in this matter, I hope Mr. Myers will correct me, as well as in any other of the details. N N, 1½-inch gas pipes for ventilation, with caps to screw on and off at pleasure, that the ventilation may be regulated as desired. Q is the porch, and it will be observed that there is a kind of air-chamber beneath it, so that no earth is allowed to come in contact with the building, which would not only sooner destroy the woodwork, but it would generate a certain amount of heat, which would find its way by conduction into the house. I shall now complete the details of the construction by giving the substance of the woodwork, not previously noticed. Sills, 8 inches by 5; middle and top plates, 7 inches by 4; centre uprights, 7 inches by 4; intermediate studs, 6 inches by 2½; outside angle-post, 7 inches by 7; inside ditto, 6 inches by 6; roof rafters, 5 inches by 2½.

I hope now I have made it sufficiently intelligible, so that should any of your readers desire to build a house on the same principle, they will find no difficulty in understanding the details. They will understand that this is a large house, computed to hold 180 cubic yards of ice. The manner of securing ventilation, although simple, is an excellent one, as although air is constantly admitted into this house, it enters the house at a point above the ice, but sufficiently low to secure a current that dispels all accumulated foul air, and in its course carries it out at the opening at the top. If the advocates for non-ventilation in ice-houses dispute this, let them go and see for themselves: I am sure Mr. Myers would have great pleasure in showing them; and if that fail to convince them of the utility of ventilating ice-houses, then they ought to be locked up for a week in one of those foul ice-melting houses where you can almost feel with your hands the thick, warm, stagnant vapour with which the ice is surrounded. Surely then they would see the importance of securing a dryer and a colder atmosphere for their ice-houses. For myself, if I had not been an advocate previously for ventilation, I must most certainly have become a convert after seeing and learning the excellent keeping qualities of the house under notice; for at the time of my last visit to see it, it was one of those very damp mild days at the close of last November, when even the external atmosphere was damp, with no movement in it; yet the internal air of this house was dry, with not the very slightest appearance of damp; indeed, so dry and clean were the inside walls, that if you had wiped them with a white cambric handkerchief, it would scarcely have been soiled.

This house was half filled with ice in the first week in March last; from that time until the end of November it had wasted and sunk 3 feet 4 inches. From the sides of the house it had wasted 8 inches; but in the first instance nothing was placed between the walls and the ice; but as soon as it had wasted about 4 inches away from the wall, the space was filled up with dry sawdust. The top of the ice is covered with 6 inches of sawdust, with a good thick layer of dry straw upon that. Both these top coverings are changed about twice or thrice in the year, according to the degree of damp they contain, and fresh dry coverings of the same materials put in their place. As to ventilation, I learnt from Mr. Myers that excepting on one week he always left the ventilators open, for he found as soon as he closed the house there was a thick damp vapour accumulating. I find, on reference to my notes, that I have omitted to give the thickness of the walls. From inside to outside, including the spaces which contain the straw and sawdust, it is 2½ feet.

The small hours of the morning now warn me that I must seek some repose; but I cannot do so without first tendering my thanks to the individual with whom many of these bright ideas first originated as to how and with what materials an ice-house should be constructed; and I would tell the reader that to reduce these ideas to practice must have cost much labour, much thought, and necessarily a corresponding amount of anxiety, until they had actually been proved in practice, as it is now our good fortune to have them before us. Nor is this the first useful lesson that has emanated from the same active mind, as these pages can testify.

In closing, I can only hope that the useful structure which has brought forth these remarks may long remain a serviceable instrument in administering to the wants and pleasures of its noble owner, as it will remain a fitting witness and testimony of the ability of the man under whose instructions it was erected.

J. C. CLARKE.

ABOUT WEATHER.

I, like many others, was taken aback last week when I read the short article in which our Editor explained that he must discontinue the system of forecasting the weather on account of the necessity of producing it so soon. Well, it is a great and all sufficient reason, and I only wonder that he has done so much and so well. Then at best it is a very bad mode of forecasting when it is practically for ten days instead of a week, and I do not wonder at the industrious camel breaking down under the extra load of another day; so it set me thinking that as I had a few notions about forecasting, and as the gardener and farmer must just as much need a knowledge of the future weather as heretofore, it would be just as well to put him on his own legs as far as possible; and so, too, I should hope our Editor, if he leaves the practice of the art, will still at intervals give us a short note or an article upon forecasting, upon the present weather whatever it may be, or upon the probabilities of the next "turn-up;" for if we must have no absolute forecasts, we will, if possible, get Hobson's choice as a sort of compensation. Now, also, let no one laugh at the matter, as so many people do, for it is, and always will be, a serious thing to all main producers of health, wealth, and prosperity; and if a man does not want to be a fool, he will keep his opinions quiet until a thing is done which would otherwise soon distinguish him disadvantageously from his fellows; this has been illustrated a few times, has it not? And now, to waste no more words, I will simply state my opinion—and more than my opinion, my belief, as I believe in my own being—that in all things there is a right way, and a right truth; also that we may find both, if we only go rightly about it.

I a short time ago purchased a small book upon weather. I dare say many readers of this magazine have it; it is a good little book: amongst other things, it sets forth fully the system followed by Admiral Fitzroy, and gives general rules for various meteorological phenomena; but it is too general—more suited to the sailor than the farmer; and then, when it comes to the more detailed practice which would be most useful to us, it is unsuited and loose. What we want is, if there is such a thing, a rule as simple as A B C, and as unerring as a beam of sunshine; or in lieu of this, the next simplest thing, whatever that may be.

Now the grand axiom of modern meteorologists is that there are only two winds, these being S.W. and N.E. for our latitudes; and right they are. They have also modes and rules for finding the results of collisions of winds, and, above all, what winds are blowing in all parts. But the farmer or gardener has none of this, and he must use his eyes to tell him what is going on; happily, if he does this as well as it may be done, he will not lack much. Now, first, I am going to show a few simple results of the rule of the winds as above stated; then I shall proceed to the subject of interlacing currents, and the way in which the barometer shows them. Now, first, if these two winds oppose each other directly, and the line of contact (the "crease," as I shall call it) lies at right angles to the currents, we see at once that the said crease will be a region of calms—a fitful calm, however, with devious gusts from any possible quarter. Now, then, suppose that the crease is E. and W. while the winds are N.E. and S.W., as above stated, then the calm will still be there; but if the winds are not entirely or almost evanescent, this crease will be very narrow, and will be bordered by winds—on the south border a W. wind, and on the north an E. wind, caused by the annihilation of the N. and S. forces of the two winds; but these cases never or very seldom occur, and I have only given them to show the next case, which is one of constant occurrence. The two winds as given above, the N.E. and S.W., are made so by the rotation of the earth, otherwise they would be N. and S. To explain this would be foreign to my purpose, and I shall tax no one with a thing which he does not need to know; but all will see that if by any force the wind is diverted from its true course, the wind will be less diverted if it is strong, and more so if it is weak: so we come at once to a grand truth, that the strongest winds are nearest N. and S., and the weakest are nearest E. and W. But this is not all. When a S. wind has gradually died away into the W., we may look for a sudden inrush of wind from due N., or a fresh rush from due S., and *vice versa* with a N. wind, as often occurs in winter time. But I am a little ahead of my subject. I showed that if the crease between two opposing winds is inclined to the winds themselves, there will be on each margin a current running parallel to the said crease, and in a direction agreeable to the wind on that side. Now, however, suppose the winds are *not opposite*; then, whether the crease be inclined or perpendicular to the currents, there will be a *differential wind* running down the said crease, and in a direction compounded of the said winds; and the less opposed these winds are, the wider will be this crease, and the steadier will be the wind down it. Now note this especially, for it is the fate of our happy land to be almost continually under one or other form of this differential wind, and the reader would be astonished if he knew what prophecies may be made upon this knowledge. The next thing to know is that this "crease," with its qualities, moves about according to a simple rule to be now shown. In this last autumn, and in nearly all autumns, this differential wind, with its crease, runs nearly E. and W., arising from a due N. (*i.e.*, a strong N.) wind opposed to the constant S.W. trade wind of the South Atlantic; and so down this broad crease there is a W. wind, and going from it northwards there is a rather quick turn of the wind to due N.; but going southward, there is a more gentle turning of it to S.W. This crease, then, is over our country in autumn; but as the sun declines, and its power to drive the S.W. wind up *decreases*, while from the same cause the N. wind *increases*, the crease of W. wind gradually retreats southward, and the wind turns N., but this not evenly, like a clock finger, but varying and capricious—ever and anon the sun getting the mastery, and driving it northward; then the cold getting the master, and driving it southward. Even every day, as the sun has power, it sends it northward, to return only at night; so, too, at this crease, between hot and cold, moist and dry, there is *constant rain*; so as it moves about we get first rain, then cold; or, being driven north again, first rain, and then warm; and if the daily motion takes place, we see at once the cause of the old saw that at the end of September, if it is a fine morning, it will be a wet day, and if a wet morning a fine day. If the seasons are steady this rule will apply with strictness *somewhere*, and generally so over the British islands. Now reverse all the above positions for the spring months, and in the increasing due S. wind opposed to the weakening N.E. wind you have a crease of due E. wind, as we all know occurring in the early spring. Then the sun grows powerful, and drives it northward. Now observe one thing, that when the mastery comes on it is *abrupt*, because the curve which the wind makes on that side is much shorter than it makes on

what we may call the "ice" side of the crease. Now bearing this last thing in mind (the abruptness of the changes), I shall consider the effect of temperature in producing interlacing and overlapping currents. The first thing to note in this part is that well-known law that warm air ascends, while cold air descends, and so we should not be far wrong in guessing that cold winds chiefly run along the ground, or in the lower regions of the air, while the warm winds occupy the higher regions; and this is the fact. So now we may at once deduce a very useful conclusion, that we always get long notice of thaws and west winds, because the currents run in the very highest regions of the air, and at once affect the barometer, while they may be days before they reach the ground level. At the present time (January 17, evening), the barometer, in spite of the frost and north wind, has fallen for about sixty hours, and it is not until now that I can detect the least bit of S.W. motion, even in the highest clouds. Judging, therefore, by the slow fall of the barometer, and the tardy results of it, we shall have a lasting thaw, and it will not come on, I suppose, before the end of the week. Not so, however, with the north winds; they come down upon us with little or no warning, and all we have to do is to be ready for them—this fact being, of course, more notable during the earlier part of the winter than the latter part. During early spring the overlapping of opposite currents is often most notable; I fancy that nearly all our cold cloudy east winds in the spring would be clear and fine but for the overlapping warm S.W. wind; at least, this was the case most especially during the last spring for weeks together. A lot of this will not seem quite to the point to the ideas of some, but I have introduced it chiefly to show a very important thing—that is, *where to look* for the wind which shall next obtain.

So one result of observing the weather with notions like these is that you seldom or never look at the weathercock, but instead of this you look at every cloud, and especially at every different stratum of cloud. Here, now, is a case: suppose the winds have been cold N.E., with frosts at night, bringing down peach blossom by the thousand, and you are anxiously waiting for release; well, look out S.W. every day, and when you see a small faint white streak in that direction, you may return, and you will find your barometer beginning to fall, if it has not already done so, and in a day or two, perhaps three or four days, the weather will turn. This rule applies equally well to the scorching summer weather we sometimes have—that is, if the wind is east. On the other hand, always be on the look-out for cold north winds running along at a low level, these especially in the autumn; it will often come down in half an hour, and woe to you if you have thousands of stock out, and it is Saturday afternoon; the worst of it is that this wind, as I have said before, will often come on without any regard to the upper currents, so that you cannot look out too vigilantly. Now in reference to all the above, it will be felt that we have no guide to tell us what the wind is doing in other parts, and so it is useless writing; but this is not the case. I can tell any one that they would be astonished if they knew the amount they would soon learn by careful attention to the subject. Especially learn to look well to windward, and always at the highest clouds, in every case except in the autumn, when after a long mild time you expect a change for cold. I do not exactly know how far off the very high clouds may be seen, but I generally reckon, under favourable circumstances, about 150 miles, and this gives an arc of 300 miles across, over which, if it is fine, you can tell at once whether anything particular is doing, for it will be well to observe that there is no great change in weather without a visible result (or rather cause) in the highest regions of the air.

It will now be time to show a more detailed view, especially as concerning the invaluable indications of the barometer.

Now first observe that a sudden fall or rise will indicate a quick result, but an early relapse into the original state; while a slow change will give long notice, and a corresponding length in the time which the new state will continue.

Now I will give a few indications of its results under the various conditions and seasons, as far as possible. First, for Spring: If frosty, a slow fall shows a tardy thaw, which will last long; a quick fall, a quick thaw, and of short duration; a slow rise, N.E. long-continuing wind; a quick rise, cold wind for a short time. A very cold strong N.E. wind will often be scarcely indicated at all, because the cold makes it rise, but the strong wind makes it fall as much. If fine and mild, a slow fall, long rain; quick fall, high W. and S.W. wind, with rain; slow rise, fine, warm or cold indifferently; quick rise, fine, most likely very cold and dry. Summer: Slow rise, S. wind, long fine weather, but colder if wind near E.; quick rise, as above, but not so durable; slow fall, wind W. or thereabouts, rain in a few days; quick fall, storms, shift winds, heavy rain, &c. Autumn: Slow rise, general motion of wind northwards, most likely by W., with cold freshness; quick rise, either cold and fine or warm and fine; slow fall, long rain, often very cold, from W. and N.W.; quick rise, high gales and mild, with wet. Winter: Slow rise, long frost, very fine if very high quick rise, very cold, fine, N. and N.E. winds; slow fall, mild and wet from W.; quick fall, much wet, and high wind from W., or perhaps snow.

The above is very rude, but may be useful; it is a most difficult thing to say exactly what shall follow certain motions of the barometer without knowing all the accompanying circumstances. And this led me to a new idea with respect to weather; and that is to make a table of several columns to indicate the change of wind, its force, direction, present weather, past weather, and at the end the resulting probable weather for the next few days. This I tried, and although very roughly I found it to give results which I have no doubt would warrant the trouble of preparing a more elaborate one, and by this the most inexperienced person might to a tolerable certainty ascertain the probable weather for from two days to a week to come.

I have not thought it needful to give a description of the various winds, as every one knows that tolerably well; but it is very necessary to note the change which will take place in the character of the various winds during the year; thus the north wind in summer is at its most rainy, and when it is we have plenty of it; so also with the east wind; but when these winds are rainy, it is because of an opposite warm wind running overhead, and the contact of warm moist air with the cold causes a continuous discharge. This is a notable thing which must always be remembered, that a wind will run over or under another for hundreds of miles without mixing with it; and you must never let your barometer deceive you when you find it is so, for it often varies without altering the weather, and this is the cause.

I think now I have given a few of the most leading points, and shown how to obtain the rest; for it is hopeless to teach it all, or even learn it all,

so that all deficiencies may be excused. I have also treated more of the winds, because they are the true causes of the weather, and if we know the wind, we need ask for little else.

Now, in conclusion, I will show the fallibility of prophecy on one point at least: it is now Saturday night, and my prophecy of Thursday in a former part of this article has turned up good for nothing. Scarcely had I written it, when the glass ceased to fall, the weather ceased to soften, and now the glass has gone up ever so much, and the frost, though not so sharp, is here still. Now all this arises from the grand truth above noted—that cold comes on almost without notice, and the change which should have reached us by now has been stopped by a thing we could not see or know of.

I hope to hear many more opinions about weather matters, and I also hope to convince many that they must learn all they possibly can for themselves. A. D.

Calendar.

WORK FOR WEEK COMMENCING JANUARY 26TH.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—Early sowings of seeds of summer crops should be made on warm, rather dry soils, the earlier the better. But on cold, damp soils there is really nothing gained by early sowing; for if bright weather brings up the plants, the next change to cold and wet kills them off, and the vexation is greater in proportion to the extent of the original promise of forwardness. Take advantage of fine weather to get all digging and manuring completed; in fact, let outdoor work now take precedence of everything else, even to the neglect, if it cannot be helped, of other matters. Crops that are specially valued for earliness, such as saladings, may be greatly helped by means of warm borders under good walls, and protection by means of borders covered with straw or reeds.

Flower Garden.

ANNUALS may be sown on open borders and in reserve beds. Any that are wanted in large quantities had best, to make sure, be sown in pans also, and placed in a pit.

AURICULAS to have water freely now that they are pushing into growth. Give air without stint. This is the best time to sow seed. Use for the purpose large shallow pans filled with fine soil, consisting chiefly of loam from rotted turves, leaf-mould, and peat. Press the soil firm in the pans, and soak well with boiling water. When the soil is cold, sprinkle the seed on the surface, and lay a flat tile or square of glass over each, and place the pans in a cold frame. Leave them alone for a fortnight; then if the soil is getting dry, place the pans in a vessel of water, so that the soil will be moistened by absorption, without washing the seeds off the surface. The seedlings will begin to show in about four weeks.

ROSES may be planted now to advantage, and plantations that need treshing and manuring may be lifted for the purpose. Put strong stakes to all newly planted standards, as if they rock about in the wind they may suffer so much injury by straining of the roots as to die in the course of the spring. Be in no haste to prune roses yet; a few for early bloom may be cut back, but the general stock should remain unpruned a few weeks.

RANUNCULUSES and **ANEMONES** to be planted now in beds of sound loam, well drained and well manured. Place the roots claws downwards, two inches deep. The safest method is to open trenches, which are to be sprinkled with coarse sand, on which the tubers are to be placed, and then covered with the soil that was taken out.

HARDY GARDEN FLOWERS.—*Eranthis hyemalis*, *Tussilago farfara*, *T. fragrans*, *Hepatica triloba*, *Leontodon taraxacum* (lovely now, though a "weed" by-and-by), *Caltha palustris*, *Primula vulgaris* in variety, *Ruscus aculeatus*, *Cheiranthus alpinus*, *Sanguinaria canadensis*, *Arabis alba*, *Draha cuspidata*, *Scilla hifolia*, *Galanthus nivalis*, *Pulmonaria officinalis*, *Vinca minor*, *Saxifraga crassifolia*, *Viola odorata*, *Eranthis Siberica*, *Iberis sempervirens*. *Frans*: Snowdrops, Squills, Hyacinths, Tulips, Crocuses, *Helleborus niger*, *Cyclamen coum*, *Ornithogalum fimbriatum*, *Bellis perennis*, various; *Coronilla emerus*.

Fruit Garden and Orchard House.

FRUIT GARDEN.—Prune outdoor vines, and train only ripe, hard wood; the distances between the rods to be eighteen inches. Complete all pruning and nailing of wall trees not yet done, and lay a good mulch of fat dung on old borders that have not had such refreshing for some time. Trees that bear well must be fed well. Many cultivators are afraid to manure fruit trees for fear of inducing a gross habit, but this is seldom the result of manuring trees that have acquired age and a fruitful habit. Of course a gross habit is not to be encouraged, but, on the other hand, if fine fruit is desired, the roots must have food enough to furnish it. Do not be in haste to begin grafting; it is best to see the stocks actually moving before putting grafts on, as in that case they take directly, and the losses are fewer than when they get a little shrivelled before a junction takes place.

FRUITS IN SEASON.—*Apples*: Ashmead's Kernel, D; Barcelona Pearmain, D; Beachamwell, D; Borsdorffer, D; Boston Russet, K; Bringlewood Pippin, D; Claygate Pearmain, D; Court of Wick, D; Count Penduplat, D; Dumelow's Seedling, K; Fearn's Pippin, K; Federal Pearmain, D; Golden Harvey, D; Golden Russet, D; Hall Door, D; Hanwell Souring, K; Holland Pippin, K; Keddleston Pippin, D; Kuke's Lord Nelson, K; Lewis's Incomparable, K; Loan's Pearmain, D; Lucombe's Seedling, K; Minehall Crab, K; Pommo Gris, D; Reinette blanche d'Espagne, K; Ribston Pippin, D; Rosemary Russet, D; Round Winter Nonesech, K; Russet Table Pearmain, D; Stanford Pippin, D; Sykehouse Russet, D; Tower of Glanmisk, K; Wadhurst Pippin, K; Winter Codlin, K. *Grapes*, same as in January. *Pears*: Bergamotte Esperen, Bueré Duhaume, Bueré Gris d'Her, Bueré de Rance, Bueré Sterckmans, Chaumontel, Colmar, Colmar van Mons, Easter Bueré, Elisa d'Heyst, Forelle, Princess Royal, L'Inconnue van Mons, Jean de Witte, Josephine de Malines, Ne Plus Meuris, Notaire Minot, Prévoist, Prince Albert, Rousse Lench, Shobden Court, Suzette de Bayay, Vingoleuse, Winter Nellis.

PEACHES and other orchard-house trees will set their fruit more freely if there is a good breeze through the house every day; the atmosphere at the same time to be kept as dry as possible. Those that have set their fruit

may have liquid manure. Peaches that have set fruit to be thinned partially, so as to leave room for another thinning. Cold draughts or excessive damp may cause the fruits to fall. Keep the temperature steady, and give air freely on fine mornings. Start another lot by syringing the trees frequently, and giving their roots a good soaking with warm water. Pot up maiden trees for fruiting next year; use strong turfy loam, with nodules of clay and a small proportion of rotten dung. Ram in the stuff as hard as if for a barn floor. Leave two inches of clear space at the top of the pot for a mulch of fat dung, and give a good soaking of water. Put the trees in the orchard-house or a cool pit; it is not well to force them into growth immediately after being newly potted.

OUTDOOR VINES must be pruned without delay. If there is any choice as to method, as will be the case with vines only a year or two planted, and which have only one or two strong rods, then the long rod system should certainly have the preference, but old fruitful wall vines must be taken as they are, and first be cleared of the shoots that bore fruit last year; next have laid in a regular distribution of last year's shoots shortened back to three or four buds; and lastly be cleared of all superfluous and crowded wood, so as to leave the bearing shoots at an average of eighteen inches apart. Pull off the loose ragged bark from the old stems, brush the wall clean, and if the roots are in an open border lay on a mulch of four inches of rotten manure, but this is not on any account to be dug in.

GOOSEBERRY CATERPILLAR.—Removal of the earth three inches deep, and as far from the stems as the branches extend, and the burial of that earth in a trench, will be as effectual a way of getting rid of this pest as any. The grubs are now in the soil, in a helpless state of hybernation, and if deposited at the bottom of a trench a foot or eighteen inches deep will never see the light again.

VINE BORDERS.—Any vine border would be benefited by being covered at this time of year; for though the vine is hardy, it is quite contrary to its nature to be so wet and cold at the roots as vines must be in this country during such weather as we have had lately. In making a fine border, take six parts good loam—if rather stiff no matter—and one part each of sand, broken bones, old plaster, and charred rubbish. It must be borne in mind that such directions as these are given in order that beginners may have a rule sufficiently definite to prevent any outrageous mistake; practical men never weigh and measure the ingredients for composts. A vine would thrive in half clean lime rubbish and half loam; or in half sand and half loam; or in four parts loam, one of sand, one of rotten dung, and one of broken bones. We have a tremendously robust Chasselas Musque growing in a walk which consists of clay trodden hard like a pavement, over which there is about a foot of coal ashes. Mr. Glendinning used to grow good grapes in a border which consisted in great part of coal ashes. To be in the full sun, and to be tolerably dry at the root, are the two golden rules for the growth of vines.

Greenhouse and Conservatory.

GREENHOUSE to be kept clean and airy, and the whole of the stock to be revised, that there may be no propagating of useless stock, and no delay in securing stock of things really desirable. Nearly all the small plants from cuttings of last autumn will now require to be repotted, and as they are now intended to grow, a generous soil may be used, rather rough, turfy, and quite sweet. Fill in round the roots with fine sandy mixture. Keep close till they make fresh roots. If convenient, have all the lights cleaned inside, and be on the lookout for slugs and woodlice, which are now coming out hungry from their winter retreats, and will do great havoc among pans of seedlings and tender vegetation of all kinds.

GREENHOUSE PLANTS IN BLOOM.—Azaleas, various Camellias, Tree Carnations, Cinerarias, Primulas Cyclamens, Hovea splendens, Acacia unciata, A. grandis, A. floribunda, A. holosericea, A. Drummondii, Brachysema lanceolatum, B. hybridum, B. undulatum, Cytisus filipes, C. proliferous, C. Atteana, C. racemosus, Dielytra spectabilis, Epacris impressa, Pelargoniums Gauntlet, Crimson King, Desdemona, Alba multiflora, Blanche fleur, James Odier, and others.

ERICAS IN BLOOM.—Petiveriana, hlanda, vernalis, melastoma, transparen, exurgens, bicolor, cocinea, echiniflora, imbecilla, Linnæana, elegans, præstans, physodes, sebana, Plunkenetiana, gracilis, peziza, assurgens, versicolor, bandoniana, grandinosa, pellucida, pinea, radiata, triumphans, viridescens, Cavendishiana.

AZALEAS to be treated as in former directions. Those coming into bloom to have a moist air and a temperature ranging from 55° to 70°. Any that are pot-bound, give a shift before starting them; the pots to be two sizes larger, plenty of drainage, and the soil turfy loam and peat, equal parts, and enough sand to render it porous. By turfy loam we mean thin slicings from a loamy meadow laid up for twelve months, with no clay or chalk in it, and full of fibre, so as to be tough and elastic. This will be very nourishing, and make finer plants than peat alone, which is of a starving nature, though essential to all these fine-rooted plants.

CLIMBERS in conservatories require attention now to remove dead wood, rub away any pushing buds that are badly placed, and to train in young shoots where desirable. Many of our conservatory climbers require a liberal heat now to start them into growth, with a free use of the syringe to keep down red spider.

FUCHSIAS are now growing freely in houses that are tolerably warm, and they must be encouraged. The Fuchsia grower should remember that the faster they are grown the better. Repot at once, using a mixture of three parts turfy loam of a mellow hazelly description, and one part each of leaf-mould, hothed manure rotted to powder, and silver-sand. If the loam is of a stiff, ungenerous nature, and no better to be got, use only one part of it, and add two parts of peat to complete the mixture. It is easier for writers to order "hazelly loam" than in some places it is for cultivators to obtain it. A temperature of 55° by night and 65° by day is best for Fuchsias newly potted at this time of year, with frequent syringing. A lot of beautiful conservatory plants may be got up with very little trouble by striking cuttings now, and growing them on fast. Shift as often as they fill their pots with roots till they are in 32-size, and then allow them to flower. If not stopped at all, but simply kept growing, they will make handsome plants, averaging two feet high and two feet through, covered with bloom in July.

HERBACEOUS CALCEOLARIAS ought now to be growing freely, and nothing will suit them so well as a warm moist atmosphere. A cool orchid house would bring them on heatfully at this time of year; but as every one has not such means of advancing them, we give a general advice that the temperature should range from 45° at night to 60° by day, the plants to

be syringed daily with tepid water, and if any indications of vermin on them to be fumigated immediately.

ORANGE TREES to be well cleaned before new growth commences. Top-dress with fat dung, and give the roots a good soaking with tepid water.

PROPAGATING BEDDERS.—As hedders of all kinds may now be propagated in quantity, the reminder may be useful that, generally speaking, cuttings put in now make fine plants, and bloom early; but if deferred beyond this time, the plants must be comparatively weak when put out, and an early bloom is out of the question.

RHODODENDRONS.—Treat the same as directed for Azaleas, but less heat will suffice to bring them out. The Sikkim Rhododendrons will do best in the Camellia house, or in a lean-to with north aspect.

HALF-HARDY ANNUALS to be thought of in earnest now. Sow according to the probability of future requirements, Phlox Drummondii, Mignonette, Stocks of all kinds, Cockscombs, Egg-plants, Tomatoes, Thunbergia, Balsam, Globe Amaranthus, Jacobina, Lobelia, Marigold, Sweet Peas, Alonsa, and any others, with the exception of Asters, and it is too early for them.

Stove and Orchid House.

ORCHIDS IN BLOOM.—Epidendrum vitellinum, Grammatophyllum Ellisii, G. speciosum, Lælia elegans, L. Maryanii, L. superbiens, Lycaste Deppii, Skinneri delicatissima, Miltonia cuneata, Odontoglossum maculatum, O. membranaceum, O. pulchellum, O. triumphans, Dendrobium moniliforme, D. nobile intermedium, D. nobile pendulum, Oncidium Barkerii, O. Cavendishii, Phajus grandiflorus, Schomburgkia crispa, S. undulata, Sophronites cernua, S. grandiflora, Cælogyne cristata, Brassavola glauca, Cattleya Walkeriana, Ansellia Africana, A. gigantea.

ACHIMENES must be started now, and the best place for them is the propagating house. But these and Gloxinias may be well done in common frames with dung-heat, with seeds of melons or cucumbers, where room can be found for a few pans of them. If they can be kept going till the end of May, with a temperature of 55° to 60° by night, to 75° or 80° by day, they may then be taken to a warm greenhouse, and will do well.

GLORIOSA SUPERBA to be shaken out and repotted in equal parts fibry loam, peat, and leaf-mould. Place in strong bottom-heat, and give little or no water till growth has commenced. It will be seen that the new growth starts from the under-side of the root, so in repotting reverse its position.

GLOXINIAS started now will make rapid growth. In planting these use the compost in a moderately damp state, and give no water until the bulbs begin to grow, after which supply it with caution until the plants have a pretty good show of leaves.

KALOSANTHES.—These showy succulents are as easily grown as any ornamental plants in our houses, and they pay well either for house decoration or exhibition. Shift now to pots two sizes larger, using turfy loam two parts, turfy peat one part, leaf-mould one part, dung rotted to powder one part, silver-sand one part. Plenty of drainage, and a layer of charcoal the size of walnuts over the crocks. Temperature to range from 45° to 60°.

ORCHIDS will in many cases require to be repotted, and after which they must have the warmest end of the house. Those that do not need a shift should have a little of the old surface material removed, and its place supplied with fresh; at the same time make fastenings safe, and repair blocks and baskets.

Forcing Pit.

CUCUMBERS are growing freely now, and as the days lengthen they will benefit by a little extra heat. No harm now in the fruiting bed rising to 80°, if care be taken to lower the temperature at night by admitting a little air, if the weather is mild, and no fear of cold wind occurring. If the weather is severe, there will be no need to cool down the bed; natural radiation will do that sufficiently. It is important to have the plants quite ten or twelve inches from the glass; if nearer, the leaves get broken every time the lights are moved. Water the bed freely with tepid water, and as soon as fruit shows stop one joint beyond it. Only allow one fruit at a joint.

FIGS to have plenty of liquid manure as they advance in growth. Pinch the shoots at the fourth joint.

PINES.—During the dull, damp, and sometimes cold weather at this time of year, pines are often injured by careless watering. It is impossible to avoid the lodgment of water in the axils of the leaves if they are syringed as freely as they ought to be; but unless that water is evaporated before dusk it will certainly do mischief. If the cultivator keeps this fact in mind, he may be able to manage so as not to incur any risk in this respect; but it may be as well to add that in the after part of the day, if there is much water lodged in the hearts of the plants, it would be advisable to draw it off with a syringe fitted with a nose instead of a rose, or by means of a piece of sponge attached to a pointed stick.

VINES started now will not need so much caution as to raising the temperature as those started in December and January, as there is now more solar light, and vegetation is active. Use the syringe freely among vines nowly breaking, but sparingly, or not at all, to vines in flower. This is a good time to put in eyes for raising a stock of pot vines. The best plan is to put the eyes singly in a mixture of turfy loam and leaf-mould, and plunge the pots in a bark bed or dung frame, with a bottom-heat of 70° to 80°. Vines in the early house to be thinned as soon as the berries are of sufficient size. Tie in the young shoots, and remove laterals early, so as to accomplish the pruning as much as possible with the finger and thumb. Be particular to lower the temperature at night. Very many of the failures in grape-growing arise through too high a night temperature.

MELONS to be put out on their fruiting beds as soon as they have filled 48-sized pots with roots. They are too often starved in pots, under the fallacious notion that when planted out they will soon recover; they should be kept in vigorous growth from the first, and when turned out have an ample and healthy foliage. In making up the fruiting bed, use very little manure. The dung-bed should be in a sweet condition to give a lasting and steady heat, and the soil for the surface should consist chiefly of rotted turf and loam. Melons require nearly the same treatment as cucumbers. They are not quite so thirsty, are more in need of sun, and should never be shaded; and they may have ten degrees more heat, if it is convenient to give it them. As melons require a more free ventilation than cucumbers, a few degrees more heat will allow of ventilation without any risk to them.

STRAWBERRIES coming into fruit need abundance of water, and occasionally liquid manure. Give as much air and light as possible, to ensure well-flavoured fruit, and those that set heavy crops thin to a moderate number, or the berries will be small.

Correspondence.

HEATING A VINE BORDER.—I have a small vinery which I am about increasing to 25 feet by 14 feet. In your number of 17th November last, you have an able article from Mr. John F. McElroy, and in the week following a leader on the same subject, both strongly recommending bottom-heat for vines. I do not want to force very early—say middle of February to beginning of March—but I wish to grow grapes in the best possible way. Do you advise hot-water pipes under the vine roots, and how many 4 inch pipes in my house? The plan I think of adopting is, that after the flow pipes have heated the top air, for the return pipes to pass under the vine border in the rubble. The vines will be planted inside, and the roots not allowed to go outside for some years. Can orchids be grown with success in the same house with vines? If so, how must they be treated in the winter when the vines are at rest?

A SEEDSMAN.

["A Seedsman" desirous of growing grapes in the best possible way cannot do better than bear in mind Mr. McElroy's advice, and take the article referred to as his main guide for preparing the compost, planting, and general management; but he may do better in the matter of warming (not heating) his border than by following the plan he describes in his letter, as a vine border should not be heated, in the common acceptation of the term. It is from the fact of too great a degree of heat having in many cases been applied to borders, coupled with the want of a compensating amount of moisture to the soil which excessive heating renders necessary, that border warming by means of hot-water pipes has found so little favour, but which judiciously applied is undoubtedly beneficial. We should advise "A Seedsman" to use 4-inch pipes for top-heat, and 2-inch pipes for bottom-heat, and further to use valves so fixed that the one may be used independently of the other, for the following reasons:—1st, the bottom

warmth should be first applied, in order to awaken the dormant energies of the vine, by setting in motion the feeders or roots. By such a course, when the leaves begin to develop, and the shoots to elongate, they will not have to wait for supplies of nourishment through lack of root action. 2ndly, In forcing in early spring, the mornings are often overcast or cold, and a fire is thought necessary, when presently a bright sun breaks out, and the heat from the fire becomes unnecessary for top-heat; it is then a matter of economy to be able to apply it to the soil, which, unlike the air of the house, when once heated, does not so soon part with its warmth; consequently, the opportunities such as above described may be taken advantage of. In order to secure the greatest benefit from pipes placed under a border, care should be taken to regulate all the adjuncts systematically, so that the heat may have fair play, surplus water be provided with a proper outlet, &c. About twelve inches in depth of thoroughly open and clean rubble, such as large flints, waste tiles, &c., from the kiln, or large burrs from a furnace, should be piled around the pipes, care being taken to exclude all fine particles, that the circulation of heat and air be not impeded thereby. Over these place evenly a thin layer of wheat straw, then a layer of soods, and upon them the mass of soil. The above diagram will show the kind of arrangement that would enable "Seedsman" to force early grapes economically. As to growing orchids under vines, we know that Mr. Robert Warner does so with success. If "Seedsman" is disposed to try the experiment, we should advise him to do so with a few only of the most inexpensive kinds, and these will have to be removed to other quarters whilst the vines are resting.]

Replies to Queries.

Gas-heating.—G. G.—When gas-heating is properly done, it answers perfectly. Mr. Lynch White, of Upper Ground Street, Blackfriars, manufactures a gas boiler which is cheap, efficient, most easy to manage, and suited for a house of any size, up to 30 or 40 feet in length.

Heating.—G. F.—A house 8 feet long by 4 feet wide can be heated to perfection by one flue. Being on a sunny south wall, this house ought to grow good grapes, though there is no length of rafter for much in that way. We should be inclined to take two rods the whole length across the rafters, instead of up them in the usual way. You could not do better than have a Black Hamburgh with two rods, or if you want two sorts, that and Buckland Sweetwater, one rod each.

Small Greenhouse.—J. Gindrod.—There are plenty of nice subjects for the greenhouse when the bedding plants are taken away; with some growers cockscombs and balsams are the mainstay, and if well grown are very beautiful. The seed of these should be sown in March, in heat; the plants will

not occupy much room till the season is sufficiently advanced that some of the bedders can be removed. As you are not rich, and want amusement, one of the very best things you can do is to get up a stock of plants from seed and cuttings, both of which you can obtain very good at low rates through the trade. The subjects you will probably find most suitable are the following, which may be raised from seed:—Herbaceous Calceolarias, Balsams, Cockscombs, Cassia tenuifolia, Datura chlorantha, Globe amaranth, Ipomea rubro-erulea (must be sown on a brisk heat), Salvia argentea. Procure also a few cuttings of the best varieties of Fuchsias and double Petunias. Many of the subjects named will be as useful in the borders as in the house. You had best not attempt raising Camellias and Azaleas from seed; it is not profitable work for beginners. Ferns you may raise from spores, with a certainty of a reward for your trouble (see reply to "Zeno.") You will not obtain seed of Variegated Alyssum; it must be grown from plants by cuttings or divisions. The green-leaved form of it may be grown from seed to any extent. Verbenas and Calceolarias raised from seed now, would bloom this season with good management; all the showy bedders may be treated as annuals, as we long ago advised for Geraniums.

Ferns from Spores.—Zeno.—There is no mystery at all in raising ferns from spores; in fact, in all well-managed fern-houses, some kinds become a nuisance in consequence of the myriads of seedlings they produce from self-sown spores. Fern spores only need to be kept constantly moist, in a still warm air; and if it be possible to raise them at all, they will germinate without special care. Some kinds are most unwilling to increase this way, but then they make amends by the facility with which they may be cut up and divided. Your simplest way to raise the spores sent you is to prepare a few shallow pans and bell-glasses. Fill the pans with very small potsherds, the top stratum to be broken to the size of peas. Over this put about an inch of a mixture consisting of equal parts fine peat and silver-sand, and water with a fine rose. The water will carry the fine stuff in amongst the uppermost crocks, and make a firm bed with minute points of crocks projecting all over; sprinkle the seed on this surface, and put the bell-glasses on. The proper place for these pans is some warm and rather dark part of the greenhouse, or the cool part of the stove will do. If they must be placed in full light, smear the glasses over with wet clay, to render them semi-opaque. To obviate the necessity of watering again, bed the pans to the rim in cocoa-nut fibre, which keep constantly moist. There are a thousand ways of raising seedling ferns if a warm, damp, and rather dark place can be found for them.

Roses.—Amateur.—If you want six to grow as standards, take Gloire de Dijon, Charles Lefebvre, Beauty of Waltham, Comtesse Chabrand, John Hopper, and Madame Alfred de Rougemont. If by three to grow to a summer-house, you mean such as may be trained on a trellis or wall, you cannot do better than have Red Rover, Boursault Crimson, and Noisette Triomphe de Rennes. The white cluster rose you inquire about is probably Aimee Vibert.

Brown and Green's Stove.—T. H. D.—From the figures and description of Brown and Green's Patent Ventilating Stove sent, we should consider this a perfectly safe and economical heating apparatus. Knowing nothing of it from experience, we cannot advise in a definite manner how you are to obtain from it a moist heat; but it appears that if the loose top is removed, and an earthen pan filled with water and put in its place, a kindly vapour would be generated that would be beneficial. One of the largest seed-pans would probably serve the purpose.

Sigma's Hoe.—R. H.—The Draw-shave hoe of Sigma is a first-rate implement. We had one some years ago of Mr. Powell, of Hurst Green, Sussex. This is the best address we can give, and we feel it to be insufficient. You might try Mr. Gidney, of East Dereham, Norfolk.

A. B.—You will find in the last number of each monthly part a *prospective* Calendar, which will enable every subscriber who takes the work monthly to sketch on the course of operations for the month to come.

J. Hurdle.—No remembrance of your letter. If it turns up, it shall have attention.

Sub-tropicals.—Alice must not expect us to advise on the best plants to grow in the centre bed referred to in her letter, because what we might think tasteful, Alice might consider horrid; and besides it is impossible to select plants for a garden one has never seen. But as we are asked definitely about raising sub-tropical plants from seed, we gladly reply that with the aid of hotbed and a few such other appliances as are required in the propagation of bedding plants, Alice may have a great variety of sub-tropicals. If canas are to be sown, the seed should be started at once. March or April will do for the first sowing of castor oil plants, as they grow very fast. The following are a few of the best varieties in the several classes named, which may all be raised from seed. We make a short list, under the impression that it will be more useful than a long one. *Canas*: *Annei, *Musæfolia, *limbata (this is the one that has stood out winter and summer several years past at Battersea Park), floribunda, nigrescens, metallica. *Solanums*: giganteum, *auriculatum, *marginatum, amazonicum, *robustum. *Nicotiana*: *Virginiana, *Wigandoides, glauca, Havanensis, Marylandica. *Ricinus*: *borbonensis, *compactus, *macrophylla atropurpurea, pulcherrimus, sanguinea, glaucus. The following plants are also invaluable, and may be raised from seed with very little trouble: Striped-leaved Maize, *Bocconia rotundifolia*, *Chamaepuce diacantha*, *Cineraria maritima*, *Ferula communis*, *Gunnera scabra*, *Wigandia caracasana*.

Peaches, Nectarines, and Plums for Pyramids.—Ernest should have given a hint of the part of the world he lives in, as we are always guided by considerations of climate in making selections. At Strood, near Rochester, Kent, where Mr. Illman has so admirably succeeded in the cultivation of these fruits as open bushes and pyramids without any aid from walls or glass, the following have been most uniformly fruitful, and except in very exceptional seasons have ripened their fruit well:—*Apricots*: *Alberge de Montgamet, *Breda, *Homskirk, *Large Early, Masculino, Orange Early, Roman, Royal, Shipley. *Nectarines*: *Downton, Duc de Tolliers, *Elruge, *Newington Early, *Murrey, *Pitmaston Orange, *Roman Red, *Rivers's Orange, Hunt's Tawny, *Violetto Hativ. *Peaches*: *Late Admirable, *Barrington, *Bellegarde, Early Anne, *Early York, *Grasso Mignonne, *Red Magdalen, *Royal George, *Violette Hativ. *Plums*: Coe's Golden Drop, Jefferson, Purple Gage, Reine Claude de Bavay, Coe's Late Red, De Montfort, Early Orleans, Mitchelson's, Belle de Septembre. Those to which * is attached are the best of their several classes.

"When was Rome built?" inquired a school inspector. "In the night, sir!" "In the night! How do you make that out?" "Why, sir, you know Rome wasn't built in a day."

The Gardener's Magazine.

SATURDAY, FEBRUARY 2, 1867.

THE ROOTS OF VINES ARE OUT OF SIGHT, and mostly out of mind. Hence, perhaps, the reason that nine-tenths of all the maladies that assail the grape have their origin below ground, though it is above ground really that we see the results. Were the roots as visible as the leaves, we should perhaps quickly discern the beginning of mischief, or, better still, detect the presence of causes before any effect could be produced, and so save the whole plant from disease, and escape the calamity of a loss of its generous fruit. But the roots are out of sight, and if causes inimical to their welfare exist in the soil, we are ignorant of the fact until it is advertised to us by blotched leaves, shanking bunches, or badly coloured and watery berries. In plain truth, the roots of vines are very much abused, not always directly; nevertheless the abuse is great, and in any hundred instances of vines doing badly we should find probably at least ninety where the evil, of whatever kind, had its commencement at the root. Take the case of vines crowded in houses with a view to secure many varieties in a comparatively contracted space. The rods are kept closely spurred (which is very proper), but the space allowed them is out of all proportion to the natural vigour of the plant, whose nature it is to spread far and wide, to riot luxuriantly, and to produce large crops of leaves and fruit, small crops of either being the mark of artificial treatment. We may restrain and regulate a plant like this to a certain extent, but we may be sure that nature will not be turned from her course overmuch, that she will resent all attempts to alter the characteristics of her children, and therefore if we restrict the growth of a plant which is naturally of rampant habit, some undesirable result must occur. In the issue for Dec. 8, 1866, we directed attention to the importance of giving a vine plenty of room, for the simple reason that it loves space and grows luxuriantly, and when a vine is allowed to cover a large space it is at once a noble object, and makes a grand return in good fruit for all the space and care afforded it. Now we call attention once more to this matter, and we invite practical men to consider that when they pinch in the shoots of a pear tree they also take care to prune the roots, but when they restrict a vine to a few rods, and perpetually check its growth above-ground, they do not prune the roots. Suppose we have a vine now before us. It has been allowed, say, to grow much as it liked, but now we approach it knife in hand, and are about to reduce it a fourth, a third, or even to one-half of its present self. We may be sure, if we reflect at all, that its roots have extended themselves in a manner proportioned to the wide ramification of its rods. Consequently, in the next season of growth it has a superabundance of roots. "And a good thing too," some practicals will say, "for now, by close pruning we shall have those roots to swell the berries, instead of feeding mere leaves and wood; by restricting the area of the vine we shall throw the strength of the plant into the fruit." That is to say, you practicals think nature a fool, in which, depend upon it, you are mistaken. Nature makes no mistakes, though we may make enough of them both in interpreting her meaning and in our endeavours to turn her from her course. What do we see in closely pruned fruit trees that are not root-pruned? Simply that they produce enormous gross rods in spite of us, and are shy of fruit. It is well known that in climates and soils thoroughly adapted to it, as for example in the Madeira and Cape de Verde Islands, and on the volcanic tuffs anywhere in the south of Europe, the grape-vine produces fruit that is truly voluptuous, while its roots are embedded in dry rocky stuff, and have literally only cinders to travel in; so fat roots are not absolutely essential to the production of fat berries. Who can doubt that a vine that is perpetually cut back and restricted as to space far below its natural requirements, must become plethoric by supplies of aliment from the roots, and so manifest some signs of disease proper to a plethoric condition? Cultivators of grapes are invited to consider this point as bearing directly on the results of their labours. To grow many vines in a house is, as we all know, quite possible, and those who take an interest in the study of varieties will carry to the nicest point possible the crowding of the space in their command, limiting each vine perhaps to one rafter. Physiology teaches that with such a system there must be combined a system of root-pruning, and

No. 92, NEW SERIES.—VOL. X.

perhaps the next best thing would be to restrict the roots of each vine to a certain space, instead of allowing them, as is often the case, to ramble far and wide in highly nutritive borders to pick up more sustenance than the leaves can elaborate. Over-feeding is quite as disastrous in its results as under-feeding, and the happy medium for either plant or animal is to have enough, and no more. We shall never have fine grapes from vines that are gorged with sap, any more than we shall have courageous dogs, fleet horses, or strong and healthy men if either have more food than the circumstances of their several lives require.

THE EMBELLISHMENT OF FLOWER BEDS IN WINTER is a matter generally neglected, and it is only on rare occasions that the parterre is occupied with ornamental plants except in the height of summer, the prevalent notions about "bedding" being of a most narrow description, and serving in horticulture for a parallel to bigotry in religion. There would be no warfare against geraniums and the rest of the popular bedders if those who love such things were actuated by a catholic spirit, and were as ready to make good use of hardy plants as they are of tender subjects that can face our climate only during the most favoured months of the year. If we look about now in the gardens, we shall see that as a rule they are destitute of beauty except in so far as they are permanently furnished with evergreen shrubs, deciduous trees of elegant outline, green grass, and sheets of frost-defying ivy. To render them as beautiful as they might be all the winter through, a great expansion of the system of decorating is needed, and nature is so kind that she offers us thousands of subjects suitable for temporary decoration, and that therefore may be grown so as to be portable, to be taken to the dressed grounds when wanted, and removed thence without harm when the season arrives again for spring or summer flowers. It is a matter of fact that at this moment, after a terrible frost, there are some gardens that look as bright and fresh and warm with winter dressing as if winter were unattended with circumstances inimical to vegetation in Britain. The reason that many gardens are not as beautiful as a certain few is that there are not many persons who know what may be done, and of those only a small proportion carry their knowledge into effect. There are unquestionably difficulties in the way of carrying out a completed system of winter decoration, and perhaps the greatest is the number of plants required and the consequent space they must occupy, and the labour necessary to keep them in condition. The extent to which winter decoration is carried must be regulated by the means at command; but there are thousands of persons who are simply niggardly in respect of the beauty of the garden in winter, and simply prodigal in respect of the summer display. The system of a feast and a fast is not a reasonable one; perpetual enjoyment is preferable to alternations of excessive gloom and excessive gladness. Generally speaking, plants intended to occupy flower beds in winter must be grown in pots and tubs, and removed to and fro as required; but this, which appears a vast labour, is less than it is commonly accounted, and during the summer the stock need not be in the way, but may be actually employed to heighten the effect of a display of flowers. We would just mention a case in illustration of this. A garden in which matters of this sort are systematically studied is made rich and pleasing all the winter through by means of coniferous trees, ivies, berry-bearing shrubs, and miscellaneous hardy subjects, all in pots. At the first break of spring, and as soon as weather permits, potted bulbs are introduced to light up the fronts of the groups. When at last the trees are removed, they are not set back in a wood yard, or as an embellishment to a muck pit, to be half killed by a roasting sun on the pots, and a miserable insufficiency of water, but are plunged in the rear of flower borders and make a rich background for displays of colour. Thus plants especially grown for winter are made useful at all other seasons, and being always in sight are always in mind, and obtain the attentions they require to keep them in health and constantly improving in size and beauty.

This winter has put to the test many subjects that have been used in this way, and to their serious injury. The golden-leaved Euonymus, the grass-green Grislinia, several of the Mahonia and Berberis tribes, and the holly-like Osmanthus have suffered severely, yet the general scheme has not been impaired, because the principal bulk of the stock consists of coniferous trees, ivies, and hollies, which no frost in this country ever seriously injures. And here it occurs to us to say that it is a downright pity that the

varieties of ivy are but little esteemed for such work as this. The variegated forms of *Hedera canariensis* and *H. helix* are equal in beauty to the most refined variegated varieties of geraniums, and during the most severe frost their leaves never shrink or look as if they had been parboiled, as the leaves of rhododendrons and aucubas do. The ivies of the *helix minor* group which branch off from the beautiful *marginalis* variety, are severally equal in beauty of variegation to Flower of the Day geranium, and indeed some of them, when cold weather brings out their tints of red, are almost rivals of the tricolors. They are sadly neglected by amateurs, for at a merely nominal expense, and with no more skill than is required to train them to neat pyramids or any other form that may be preferred, they may in a few years be grown into compact and handsome bushes, and indeed the fruiting forms of ivies naturally form elegant trees, and their leaves glisten with health, and have the freshness of a May meadow all the winter through.

We have lately seen some garden vases which it was the custom of the proprietor to furnish with flowers all the summer, and with nothing all the winter. But having read some articles in these pages on the "plunging system," he tried his hand at a little plunging with these vases in order to judge how far he might carry it in the treatment of the flower garden. The vases were cleared of the mould in which the summer plants had been grown, and were filled with cocoa-nut refuse instead. During the autumn they were furnished with hardy ferns in pots plunged to the rim, and with a sprinkle of the fibre to hide the pots from view. The first frost spoiled the look of the ferns, but of course did them no real harm, and they were removed, and collections of ivies were employed in their place. The effect was fully as charming as before. Some of the trailing ivies were untied and carefully pegged down, so as to appear as if grown *in situ*, and towards the centre were placed neat dwarf bushes of the fruiting or arborescent ivies. These are now as fresh and unhurt as if there had been no frost, and in one of the vases is a central plant of a new variegated tree ivy, supplied by Messrs. Lucombe, Pince, and Co., which is really equal in colouring to the best creamy-leaved geranium known, and as respects contour and leafage, a vast deal handsomer, for it is a symmetrical tree, densely clothed with neat small leaves that appear to be disposed in a regular system of imbrication all over. There are myriads of plants adapted for such work—the *Skimmias*, the gorgeously berried *Pyracantha*, the new *Aucubas* with their splendid liveries of gold and silver; indeed to begin to name would be to enter upon catalogue making, and we content ourselves with having once more directed attention to the subject, and in doing so we invite our readers to observe now the beauty of the commonest ivies and hollies, and from their fresh and unscathed appearance to conjecture what might be done with selections of varieties of hardy plants grown expressly for winter embellishing.

A SIMPLE MODE OF GROWING POINSETTIA PULCHERRIMA.

This beautiful plant is usually recommended to be grown in the stove and tan pit, as our great-grandfathers used to grow them, when at the completion of their growth they generally measure from 5 to 10 feet high, with two or three leaves on the top, and a few red bracts a little larger than a mouse's ear. I went over to see an old friend the week before Christmas. There I beheld the most delightful group of Poinsettias ever seen. The plants were from 2 feet 6 inches high, with every leaf perfect; some of the old plants had five or six heads of bracts on them, measuring from 1 foot to 15 inches across; and as there were two or three dozen plants together, they made a perfect blaze of colour. These plants are cut down at the usual time in spring, and are placed in a cold frame, kept rather close, until they begin to grow. When the new shoots are about an inch long, they are shaken out of the old pots, and repotted in smaller pots, in a light rich soil. Again they are kept close for a few days. They are next fully exposed to the weather by removal of the lights altogether in fine weather; but the lights are replaced in wet or cold weather. They are shifted into their flowering-pots when they require it, and the strongest shoots are stopped as soon as they begin to take the lead. They must have plenty of water; if allowed to flag, they will lose their foliage. They must remain in the cold frame until the end of October, when they require a little heat, with plenty of light. A little liquid manure will help them as soon as they begin to form their bracts. When treated in this way they are splendid objects for winter decoration.

E. MITCHELL.

Lower Broughton, Manchester.

THE POTATO AND ITS PARASITES.—It is stated in *La Patrie* that "the microscope reveals to us the existence of a small black spot of the diameter of a pin's head, in the potato. In this small space can be detected some 200 ferocious animals of a coleopterian form, which bite and tear each other with continued fury. It is easy to comprehend the potato disease when such an intestine warfare is raging." [This is BOSH. Ed. G. M.]

BEDDING GERANIUMS.—No. XXXVII.

To return to a well-worn theme is something like making a visit to an old friend. It may be so for both writer and reader, and for both it may be otherwise. Writers of newspaper leaders have to return to well-worn themes hundreds and thousands of times, and are always expected to say something new about them, and too oft perhaps they and their readers are alike sick of the occasion that calls them together. Wanted of Ipse Dixit, Esq., his 437th leader, full of sound and fury, on the absolute necessity of making parochial officials sign the Thirty-nine Articles, and swear allegiance to the Brunswick family. The learned chiel can do it, perhaps, like the good wife in the "Cotter's Saturday Night,"

"Gars old claes look amast as weel's the new."

for the quick-brained man who watches events finds in them new and endless illustrations of any doctrine he has espoused, whether in theology, politics, or morals. But we are eternally absolved of the possible miseries of the dispenser of political opinions. Nature is a kaleidoscope into which we may peep for nothing, and if we want to be wise or happy, we scarcely need do more than carefully write down the nature of the patterns and the colours shown us. Thus our theme, which has now dragged us into No. XXXVII., is of necessity as fresh as ever; for the kaleidoscope has gone round, and a new chromocosm looms upon the view for our delight, astonishment, instruction, and amusement. As Horatius sighed for Glyceria, and as a scalded poet of these times would sigh or cry for Glycerine, so the present scribe is inclined to sigh for Geranos or Pelargos, or any other —os that the complications of the chromocosm may reveal—"the same as 'twas, yet differing altogether." Ah, Horatius, you have the best of it, for in your days there were not so many varieties of geraniums as now, and Glyceria may have been the emblem of the genus, and a microcosm of all its beauties.

*Mater seva Cupidinum
Thebanæque jubet me Semcles puer
Et lasciva Licentia
Finitis animum reddere amoribus.
Urit me Glyceræ nitor
Splendentis Pario marmore purius:
Urit grata protervitas,
Et vultus nimium lubricus aspici.
In me tota ruens Venus
Cyprum deseruit; nec patitur Scythas,
Et versis animosum equis
Parthum dicere; nec quæ nihil attinent.*

(Carmen xix.)

No, farewell slumberous ease, and the cultivation of obesity. The winter is past and gone (at least for the present), and I seek the flowery nymph whose velvet cheeks, whose bright green robes, whose eyes of inimitable lustre have charmed me so oft, and who, unlike "the shining maid" that Horatius doted on, offers her charms to all, and yet remains an emblem of virginity. Come ye, and behold my beloved. She has already crowned herself with a chaplet of flowers to hail the newborn spring (that is, if the spring is come, which is doubtful); and we cannot say that other loves have made our eyes insensible to charms that are matchless, and that are ever renewed and renewing. But why go back to Roman bards that were half their time fuddled, and when quaffing purest Castaly were oblivious of the properties, and had never seen the nymphs they maundered about! Wanted, a floral laureate for the modern time, to sing the praise of every flower; and in respect of this, the most wonderful of all to startle humanity with such a song as this:—

Of all my talk this is the sum,
I speak it plain, without a hum;
And were I at this moment dumb,
I'd blow the trumpet, beat the drum,
In praise of the Gerani—um.

Well, we are getting now into the heart of the subject, through the help of imagery and allegory, and by the time we arrive at No. 100 we shall be perhaps enabled once more to discuss, as we have been wont, the merits of the candidates in this department for favour and for fame. We must bear in mind the relations of things as Cicero has so plainly and prettily put it (*pro Archia*), *Etenim omnes artes, quæ ad humanitatem pertinent, habent quoddam commune vineulum, et quasi cognatione quædam inter se continentur.* Thus we get a hint of the way to go; the arts that concern some of us as cultivators of polished life, and of flowers as pertaining thereto, are held together by a common tie, which is the perception of beauty. And a house that I could show you now—I mean a plant-house with a thousand varieties in all the freshness of first trusses and new leaves—would prove the postulate, for they are like the members of a mutual improvement society, each contributes to the illumination of all the rest. *Italia Unita, Rainbow, Luna, Countess of Warwick*, and fifty more of the tessolated series, unke an Alhambra flooring, above which shine the rosy, orange, scarlet, white, and purple flowers of hundreds of varieties that burn the brightest in the wondrous chromocosm that the geranium has

discovered to us, and which has (as per example above) lifted us out of prose into poetry. Now let us look at the case from the utilitarian point of view. A good collection of geraniums will afford amusement for all seasons, and on every day throughout the year there will be amongst them something worth looking at. If well managed, there will be more or less of flowers all the year round: fewest in December and January, abundance from April to July, a blaze of any colour—red fire, orange fire, purple fire, any kind of fire from a dull red to a white heat, in the open ground, from the end of May to the end of September; and when flowers are scarcest, some of the variegates will make a display that may be likened to the poetical bottom of the sea, which of course is paved with rubies, topazes, emeralds, and other gems that dazzle the beholder (especially if his name be Endymion), and convince him (if he has any sense) that he may seek far and wide in the constituency of Flora for a coterie to match them for variety, splendour, and perpetuity of attractions. I have just gathered trusses of *Eugenie Mezard*, *Amy Hogg*, *Beauty of Brixton*, *White Perfection*, *Excellent*, *Stella*, *Madame Barré*, *Herald of Spring*, *General Pelissier*, *H. W. Longfellow*, *Kate Anderson*, *Wiltshire Lass*, *Lady Cullum*, *Indian Yellow*, *The Clipper*, *Le Grand*, *Magna Charta*, *Madame Werle*, and *Amelina Griseau*, and I have grouped them in vases with a foundation of leaves of *Alma*, *Cloth of Gold*, *Lady Palmerston*, *Mrs. Pollock*, *United Italy*, *Mrs. Benyon*, and *Countess of Warwick*, and it is summer somewhere, for who can talk of winter with geraniums in flower? and who can grudge the cost of such a bouquet when to keep a thousand plants through such a frost has not cost one pound sterling for consumption of coke? Iago was nothing (or at least a scoundrel, which is nothing) if not critical, and I am nothing if not practical. I liken myself to that wretch, to cut from under the feet of any possible traducer the smallest argument that might be used to prove me vain or egotistical, and I give you "facts that winna ding, and dinna be disputed." An airy house, abundance of light, a good 4-inch piping, a trusty boiler, a man who despises sleep on the night of January 3, 1867, a batch of specimens, and a nursery of young plants, and there you are—

Where you would ever be,

The blue above and the green below,
And the flowers around you wherever you go;
And nobody near to say it is wrong
In the way of geraniums to come out strong:
Which lines from the text are a little altered
From Barry Cornwall, who never faltered;
For he sang of the sea, and that you see,
Is all the better for you and me,
Because the remoteness of his allusion
Relieves us at once of all confusion.

The rush in the spring, amongst buyers of geraniums, is always for bedders. The broad petals have not yet taken the fancy of the crowd; they were too good for the million, and like all the lave (pure Scotch) of florists' flowers, are for the enjoyment of such choice spirits as have been admitted to the courts of the Queen of Beauty. Yes, the rush will be for bedders, and to please the million (whose twopences are acceptable) I will just delicately hint that in the list of the novelties there are a few bedders that will shine like remainders of the last meteor shower, a few of which fell into the geranium world, and took root in the catalogues. The best of all the new bedders is *Lady Constance Grosvenor*, a burning and a shining light amongst the nose-gays, the colour nearly that of a ripe orange seen through blood-red glass when the sun shines fiercest on the longest day; and so free to flower that it doubtless comes up to the standard of extreme possibility that way. Next best, and a bedder all over root and branch, is *Duchess of Sutherland*, in the way of *Stella* as to growth, in the way of *Amy Hogg* as to colour, but passing both in richness, softness, purity, profusion—lustrous as the best moments of a dying dolphin (*vide* Byron, somewhere), and persistent like folly, which is always in full bloom except in uninhabited islands. After this dash at two glorious subjects for the garden, I cast about, and in the way of a butterfly settle upon *Christine Nosegay* as worth five shillings a plant anyhow, though I know not what is to be the first price of it. If you want to realize it, you may picture *Stella* without a change, except that the flowers are Christine colour; or, better still, go to Wellington Road, and coax one of the foremen to find a plant in bloom; and, as a rare fact, there is one in bloom now, and if you are quick you may see it ere it is discovered by the propagator, whose sole business in life it is to cut these things down with the same impartiality that literary critics cut other things up. For a large bed which shall shine like a streak of auroral lustre, and persuade Venus, as she saunters by dreaming of love, that roses have flung away their glories for ever, Christine Nosegay has no match, and Christine herself must end her days in weeping. The benign fosters of Wiltshire Lass will offer *Fair Helen*, captivating as her of Troy, but demanding less blood for her vindication. Downie, Laird, and Laing have nothing better than this in their glorious collection—nothing more chaste, more delicate, more like the coy beauty of blushing fifteen. Shall we call it blush warming to tender

pink, or shall we leave the cultivator to discover the colour, and name it if he can, giving him meanwhile this encouragement, that at any figure under a guinea a plant of it will pay him some day? Yes, that is the course; read Homer while it is still possible to sit by the fire; and when Fair Helen offers to smile upon you, turn not away from her bewitching glance. I like *Blue Bell* for its gentle, hinted, but not expressed, mauvy shade of lively rose; *Crimson Perfection* for its depth and richness; *King of the Nose-gays* for its dwarf habit and abundance of orange-scarlet flowers, beating Harry Hicover, Harkaway, and all that set; *Lord Lyon* for its fine round trusses of pure scarlet, combining the best qualities of *Stella* and *Boule de Feu*; *Mrs. Laing* for carriage and effect, which are the result of a combination of good qualities—good growth, neat leafage, large trusses, dwarf habit, and the colour crimson-scarlet, and the petals broadest of the broad for a true nose-gay; *Pink Queen* for good average qualities, the trusses medium, and plenty of them; and there my list of bedders for 1867 comes to a close. I have selected ten out of a crowd that are preparing for a rush, and I say those ten are good, and of the rest I say nothing, for many of them may be good or bad; but in this business we guess at nothing, and we hold to the doctrine that seeing is believing, if you know what you are about. If you want a pick of six, my choice is *Lady Constance Grosvenor*, *Duchess of Sutherland*, *King of Nosegays*, *Christine Nosegay*, *Fair Helen*, and *Mrs. Laing*. Some of the novices will, as always happens, order in all the new varieties. We must not, dear friends, present to the world illustrations of the adage about the fool and his money; we must write in the first page of our note-books a motto from Virgil, *Moniti meliora sequamur*. S. H.

THE MICHAELMAS DAISIES.

How often was the mixed border filled with thoroughly weedy and dingy Michaelmas daisies, and solidagos that are not worth a place in the wildest of shrubberies or rubbish-heaps! Ill weeds grow apace, and so did these wretched species of American aster in our old flower gardens. They monopolized the border to a great extent, and no wonder that, with other herbaceous plants allied in ugliness, they helped to drive out of cultivation this charming source of interest to the horticulturist. But there is a great amount of beauty in the genus, and that of real utility for a British garden of hardy plants, as some of your readers must be well aware, and my object is to endeavour to select and recommend the very best only. "Selection, not collection," must be our motto, particularly in such large and monotonous genera as the aster, although if we select all the really good things that may be had in the hardy plant way, the "collection" will not be very limited.

I have gathered flowers this day (October 6) from what was the prettiest plant in flower in a botanic garden, and that was *Aster elegans*, a plant growing about 4 feet high, and producing masses of rather small flowers of a delicate pale lilac, the shoots having a somewhat pendulous graceful disposition, and the effect being of the most charming kind. I consider it the most valuable of all the asters, and one worthy a position in every garden where hardy plants are grown, because it has a peculiar merit in flowering regularly and profusely, coming in before *Novæ Angliæ* and *Novæ Belgiæ*, and thus having a much better chance to open than these kinds, which often get knocked out of all health before their flowers come to anything. It would associate beautifully with the last blooms of *Tritoma glaucescens* and the best of *T. grandis*. Its distant effect is better than any other aster I know, because at once graceful and producing a shower of pleasing colour, while closely examined it is also good—good enough to go among baskets of cut flowers and the like. It is named *A. cordifolia* in the scientific collection at Kew, though in the mixed border it will be found under the name of *elegans*. There is a large-flowered form or distinct variety of this plant, not so pretty as *elegans*, and with somewhat larger leaves, that I propose to call *cordifolia*, and let *elegans* distinguish the most graceful and densely flowered kind, as it is certainly the most elegant of the genus I know. *A. turbinellus* is a beautiful species, with a somewhat spreading and refined habit, and large-rayed delicate mauve-coloured flowers. It grows nearly 3 feet high, and blooms profusely in October. A most respectable species for the mixed border.

I like variety, and therefore will at once descend to a species about 7 inches high—from a horse to a harvest mouse in fact—that is *Aster Reevesi*. I don't know its native country, nor do I care much, but such pretty little stiff bushes of starry flowers are quite a novelty in the genus, and it is most worthy of a spot in the front edge of a mixed border or rockwork, or even for an edging for an autumnal bed of some kind. Cheap and plentiful at Wellington Road. Near it in point of size, showing large blue flowers, is *pulcherrimus*, rather straggling, but still good and distinct while not yet in flower, and always extremely pleasing to me from

the remembrance of what pretty bushes of it I have seen on fine autumn days. Equally good is versicolor. A round, dense, neat little plant, the flowers changing from white to a pale rose (don't be too precise about the colour nomenclature); the two-coloured flowers have varied blooms, producing quite a distinct and novel effect for an aster; a most beautiful plant for the front edge of a mixed border, a large rockwork, or indeed for many positions about a tasteful garden, coming in to give us a little hope and beauty just when the sun is giving way to fog, and the clear air to the "evil humours" of our nasty winters. A capital plant, too, to make an edging round a bed of Tritomas—grandis being in the middle to look grand to the end of the season, and this being used for an edging. It grows about a foot, or a few inches over it, according to soil and situation.

Aster linifolia is a pretty and dwarf species, flowering rather early, worthy of a place in an extensive collection—though where a limited selection is only grown it may be left out with advantage. Aster repertus is a very free and fine species, growing about 4 feet high, and bearing most profusely pale lilac flowers with yellow centre; a valuable species. A. laxus is a very good kind, with large flowers; A. Drummondii, a very tall kind, and rather good; A. mutabilis, somewhat like turbinellus, but smaller, suited for a full collection; A. dramosus, a most dense-flowering fine kind. A. lævis is a very good blue kind, somewhat over medium size, a nice border plant.

That fine one with the rather large simple leaves and boldly rayed flowers, of a good honest blue, is A. amellus, one of the best dwarf, medium size, free and early flowering; among the very best, and pretty well-known therefore. We will pass on to those equally well worthy of an introduction. I cannot say that I know as much about the genus as I should like, though I have for a long time kept my eye on the better kinds, but I do not know a more interesting one among them than grandiflorus. It flowers very late at Christmas, and to see it in full beauty we must plant and nail it against a low warm wall: just such a place as many devote to myrtles would suit it to a T, and it would look very well indeed among chrysanthemums in such a position. I have never tried it in a pot, but it may be worth that trouble. A. coccineus has been named to me as a good one, but I don't know it. A. ericoides is pretty good; horizontalis middling; lævis and patens highly recommended, but I have not seen them in good flower, and therefore cannot positively say. One I saw just opening its flowers to-day, named A. Shortii, I have much hope of; it is of spreading, elegant habit, and has medium-sized flowers of a delicate mauve.

A. Novæ Angliæ has long been known as a fine strong kind, especially its reddish variety of ruber, and Novæ Belgii is also fine, though for my own part I don't care about either, as they come in a little too late, and get hurt—never make a good free head of flower in fact. A. puniceus and pulchellus are said to be good, but I have not grown either of them. As for the names, you must take them *cum grano salis*. To name and find the differences between a large plantation of asters would be about as easy a task as finding specific differences between the hairs of one's head. I am looking for the most distinct and beautiful of this and all other hardy plants, and should be much obliged to any of your readers who can recommend a really good addition to the genus, or throw any light upon the matter. Mr. M'Nab, Mr. Niven, Mr. Osborne, and not a few others of your readers would be able to assist in this matter, I have no doubt. Only we want a higher standard of excellence than has been yet applied to such plants. It is the bad scraggy plants that have ruined the cause of hardy subjects in this country; but once let people know what a mine of precious wealth there is within easy reach of them in this way, and you do more for their taste and gardens than by any other means that I know of.

In conclusion, I saw a very pretty dwarf kind, named "monstrosus," at the Wellington Road Nurseries the other day. A. sericeus is pretty and distinct; A. foliosus, neat and late; multiflorus, white, neat, and diffuse. Alpinus has solitary flowers, with large purple rays, dwarf and neat. The white variety is also good, and the variety altaicus; and that is all I can call to mind of real merit among a host of kinds utterly devoid of any beauty that would make them worthy of a place in a garden.

ASTER ELEGANS.

THE POET LAUREATE ON THE STUDY OF NATURAL HISTORY.—Mr. TENNYSON in a letter to Mr. White on this subject, says:—"I heartily agree with you in the desirableness of encouraging the study of natural history, especially among children, whose eye can be so easily educated to observe, and whose restless natures must have some occupation—and that, too likely, harmful if not good—at an age when nothing can be indifferent, it indeed, at any age anything can be really indifferent. The dullest country can scarcely be dull, if, as child or man, the human being can look with seeing eyes on the things around him; the most difficult outward circumstances can hardly be without remedy if he be aware of even a small portion of the mystery and might of the nature that surrounds him. He ought to learn this practically."

ACHIMENES.

We may and do often differ in our modes of cultivating particular classes of plants—not so much as a matter of opinion, but from the circumstances which influence our practice. However, if we accomplish our object, it matters little as to the plan we have pursued in attaining it, although we must not too easily content ourselves by supposing we have realised it. The treatment of our various popular flowers has constantly exercised the pens of our horticultural writers, and yet we cannot deny but there are some facts we were not previously acquainted with to be gleaned from each of them as the reward of experiment and observation—for example, as with architecture, each architect invents a peculiar style of his own, yet the object sought by all in the main is one and the same, and every man's style bears relationship to models that are common to all. I have often thought when visiting some of our great metropolitan shows that it is to be regretted there is not more encouragement held out in the schedules to exhibitors to compete for prizes with such useful decorative plants as Achimenes, Gloxinias, Cinerarias, and a host of other useful plants which cannot be dispensed with in furnishing our conservatories. I cannot say why they are omitted by the framers of these schedules; whether it is they consider they will not interest visitors generally, I cannot say, but surely if they interest at home, then they must of course be alike interesting elsewhere. The promoters of our local horticultural exhibitions quite understand their value, and therefore they hold out every inducement that may aid the progress of horticulture and floriculture generally—as the exhibitors are not influenced in their competition, as a rule, by mercenary motives, but a desire to excel in the growth of their several productions. And yet notwithstanding the indifference shown towards these classes of plants by the managers of our large exhibitions, their judges are instructed to commend and award prizes to seedlings of merit. But perhaps they consider their cultivation too simple to render them worthy to be exhibited in general collections, as compared with our stove and greenhouse collections, such as Ericas, Azaleas, &c.; but I contend that to manage and grow them fit for exhibition, there is the same amount of care and watchfulness required. And why? Because they have to acquire, in a very short space of time, that healthy vigour which is essential for producing size and abundance of blooms. As regards colour, they have all the delicate shadings which belong to other flowers, and they present us with variety and brilliancy. With me the Achimenes has always been a favourite flower, although when I began my first steps in gardening I only became familiar with one variety, and that was *coccinea*, then known as *Cyrilla pulchella*; afterwards its name was changed to *Trevirania coccinea*, and now we have it named *Achimenes coccinea*. The treatment of the plant in the regulation of its growth was years ago somewhat different to the present method. Many growers never placed more than one plant in a pot, and they were truly examples of superior cultivation, being so managed that by the time their flowering season arrived, one plant would have required an eight-inch pot, and have attained a size measuring nearly two feet in diameter, and upwards of eighteen inches in height, clothed as they were with quantities of scarlet blossoms, and presenting a unique pyramid. The same kind of heat, moisture, syringing, and watering was afforded them as is now adopted, only that by the system of growing one plant in a pot much more attention was required in the training, stopping, &c., as compared with our present practice.

Now from the very ready way in which these roots are increased, and the great number of sorts submitted to us for our choice, we do not pause to bestow so much skill in the growth and training, but grow some eight or nine plants in the space occupied formerly by one. Whether we are the gainers by the thickly planting system, I shall not stop to argue; but one thing is certain, that where there is a crowding of plants together the result must be a weakening process, as contrasted with a single plant grown in the same space. However, in planting a number in pots or pans do not overcrowd them. The distance from plant to plant should not be less than an inch. I have seen them growing in pots manufactured on purpose for their growth, having holes at equal distances perforated round about three parts of the depth of the pots' outer surface, into which the bulbs or plants were inserted. The effect of this method when the plants were in flower was grand, as so growing they were well adapted for exhibition, as when staged nearly all parts of the pots were hidden from view by their foliage.

The present month (February) is about the best time in the year for commencing their culture. If you have preserved them during the winter in their last season's flowering pots, let them now be carefully shaken out, selecting only the strongest and ripest roots. If you can obtain a sufficient number of the latter for your use, you may then place them thickly in a shallow pan of light soil, or put several roots in large 60 size pots, after which put them in a moist bottom-heat. Shade them so that they may need little water till they commence vegetating; when they have grown an inch or more

in height, let them be transplanted into their flowering pots or pans. If you plant them in large pots, let one-third be filled with drainage, placing a little moss or any kind of fibrous matter over the crocks to prevent the soil getting internixed with them. It is not a great depth of soil that they need, so that if there is an insufficiency of drainage the latter is apt to get stagnated, and no after-inducement can persuade the plants to progress. The compost most suitable for their final potting is a mixture consisting of light loam, leaf-mould, and a little peat, with sufficient silver-sand to keep it porous. But the great essential for promoting healthy and vigorous growth is a warm moist bottom-heat, and as they advance in growth they are partial to a gentle syringing when closing the frame or house in the afternoon.

Shading must be carefully attended to, and under no pretence neglected, as the consequence will be that the leaves will be scalded, so that no after-efforts can remove the disfigurement of the foliage. If they are grown in a pit or frame by themselves, it is advisable to admit air freely very early on fine mornings for an hour or so before the sun's power increases, the object being to dry the foliage, and allow the escape of all noxious vapours. As regards what is the best means to be employed for applying bottom-heat for growing them, that must entirely depend on the conveniences at the disposal of the cultivator. It is not every gardener that has the advantage of a pine pit or a hot-water tank. But very few indeed there are that are minus of the primitive but simple mode of applying it by means of hot manure. For the information of my readers I must observe that the strongest and best *Achimenes* that I ever saw cultivated were in pots plunged in a common dung bed, and I have never surpassed them by any other method either in strength of plant or size of bloom. As soon as they require supporting, let them be neatly staked. This should not be delayed after they begin to show a disposition to become straggling in their growth. Remove them to a shady part of the stove, as near the glass as possible, not forgetting to exercise every precaution against scorching the foliage. As the flower-buds expand, gradually prepare them by the change of temperature for the conservatory. When they have ceased to bloom, by degrees lessen the quantity of water, ceasing only when you believe the plants have finished their growth, and produced large and sound roots for flowering in the ensuing year. Then store the pots away on their sides in any out-of-the-way corner of the stove, so long as it is dry and warm. As an experiment, I have allowed them to grow and flower two years in succession without disturbing their roots or otherwise re-potting them, but just thinning out the weakest as they grew. I would not advocate the practice, as I did not gain by it, but on the contrary the flowers, though plentiful, were small, and but of short duration.

The following list comprises some very good old useful sorts. There are improvements on many of them, I have no doubt; but my province is to mention only those I am acquainted with.

Ambroise Verschaffelt.—Fine white, starry centre; early and very abundant bloomer.

Carminata splendens.—Beautiful carmine, and exceedingly free.

Coccinea grandiflora.—A grand improvement on the old scarlet variety.

Longiflora.—Blue, a good old useful variety, free bloomer, early.

Longiflora alba.—Pure white, free bloomer, but weak flowers.

Rosea elegans.—Carmine, compact grower, small but free flowers.

Sir Treherne Thomas.—Strong grower, rich crimson flower.

Viola semi-plena.—Very pretty purple flowers, good habit.

Carl Wolfurth.—Purplish-crimson, profuse bloomer, very good.

Grandiflora.—Rosy-purple.

Longiflora major.—Large blue flowers, very strong grower.

Metcor.—Very brilliant scarlet-crimson, good habit, and very attractive.

JOHN F. McELROY.

ON FURNISHING CONSERVATORIES.

Many thanks to your contributor, Herr Karl Prosper, for his excellent articles on Palms and Cycads. I read them, and was more than pleased with the remarks they contained, and I can bear him out in most that he said concerning them; and as I have been getting a collection of palms and cycads together for these last three years, and have up to the present time succeeded in securing somewhat about forty varieties, you will say I am getting pretty rich with them, and so I am, and in spite of the saying, "One can have too much of a good thing," I don't think so as far as palms are concerned, for I find them the most useful plants there are for furnishing my conservatories; a goodly quantity I have to do too in this neighbourhood, and wherever I introduce palms in them I always please my patrons, especially the ladies, who are no bad judges, mind you, where taste and arrangement of plants and flowers is concerned—

For there is that taste in a lady's mind
That in a man's you can't expect to find.

But to pass on to arrangement of the conservatory. Some three years since, before I tried palms, or, in fact, before I had any to try,

I used to furnish my conservatories in season in the usual way, viz., a few azaleas of different colours, and nicely in bloom, as well as a few camellias, interspersed with hyacinths, roses, mignonette, and such like: all very pretty and gay and sweet withal. Just so; but still, after you gazed on it a few minutes, you could see there was something wanting. It looked gaudy and flat, just like a bouquet would be that was made up with all flowers, and no green leaves about it. Not enough green, I used to think. So I introduced a few Oleanders with one or two large Camellias, also a plant or so of *Rhopalax* and *Grevilleas*. Well, it looked better, but rather too stiff yet. But just at this time chance threw in my way a few large palms. I bought them (a lot of money they cost too; but never mind); and introduced them in my conservatories among my flowering plants. "There," says I when I had finished arranging them, "There is effect for you now, if you like!" and there was effect indeed, for the dark green of *Chamærops excelsa*, and the light green of *Seaforthia elegans*, with the bold exotic appearance of *Latania Borbonica*, with their drooping leaves overhanging and blended with the gay azaleas and geraniums, was a sight worth seeing; for there was perspective now as well as groundwork. My palms certainly were large, somewhere about six feet in height, so there was something to look at. Well, from that time I have gone on increasing my stock of palms, and I always recommend them for furnishing, feeling confident they will please wherever they are used. And another grand thing about them is, you may do just as you please with them; they never seem to have too much knocking about. I have had them out for six months in a stand in a room where but little light could get at them, and after the lapse of that time they came out none the worse. Now I don't think I can say more in their favour than this. Touching the matter of the soil they require, that has been so ably set forth by Herr Prosper, that I will only just add, I have used more peat and leaf-mould than he recommends for them, and I find they like it, but they are not very particular, for soil that would do for a fuchsia would suit them.

I now come to their hardiness, and the weather we have had lately enables me to say something on that score. I had out in a conservatory near here the first week of this year the following sorts, viz., *Latania Borbonica*, *Chamærops chinensis*, *C. serrulata*, *Seaforthia elegans*, and a large plant of the wine palm, *Caroyta urens*. The place, unfortunately, was badly heated, and we had about 8° of frost in for a short time on the 4th inst. It of course froze the soil in the pots as hard as bricks; but, however, means were resorted to and the frost got out, and has been kept out ever since. But the wine palm is I fear quite killed. All the others appear none the worse—not even the young leaves touched or discoloured. But should any of your readers feel inclined to begin growing a few, it will be best just to mention the place they are to be kept in, that they may be selected accordingly, for if the place be a stove or sitting-room, there are some sorts that will be sure to do for the purpose. But I fear I am running on the palm subject too much for you, and discarding many other plants that are useful for furnishing conservatories as well as them, but we will do them justice in another article another time, for I find my letter is just full. I will therefore wind up with a little episode I noticed at the workman's exhibition of plants at the Agricultural Hall in September last. As you are aware, I exhibited some palms and tree ferns, and other plants, and amongst them several nice tufts of *Sibthorpia Europea*, or Cornish Moneywort; I use it chiefly for covering over the tops of the pots or tubs that contain the palms, &c. I had one nice tuft of *Sibthorpia*; it quite covered a 16-inch pot, and also hung down over an inverted 24-inch pot that the plant stood on; in fact, it was just like a wig. Now this was strange to most of the visitors there, and especially to a hard-working looking couple, about 26 or so, who stood for some time in front of it looking at the mass of green. At last the woman said, "Why Bill, that's mustard and cress, growing all of a lump, and upside down." "Get out!" says Bill, "that's a new sort of musk—can't you smell?" "No," says she, so she leant forward and poked her nose close to the mass of green, an opportunity for mischief not lost on Bill, for at the moment Bill's hand was at the back of her head, and bob went her head, or rather her nose, amongst the green. Of course the bystanders laughed heartily, and I was as bad in that respect, but still there was no harm done, but at the close of the show there were evident marks of other noses having been buried there. But more anon.

JOHN BURLEY, F.R.H.S., &c.

Albert Nursery, Pembridge Place, W.

GARDENING FOR COLD WEATHER.—During the present inclement weather, don't set anything—not even your foot—in your garden. This is rather too early for sowing, but a little darning may be done. The chief operations after Christmas will be found to be pruning your outlay and cutting down expenditure. If you don't like this, and prefer hoeing, you can (h)ove your butcher's bill. Things are apt to be backward with such variable weather. If your crops don't come up, there's no remedy for it. Should your dinner, however, not come up when you ring, you can ring again. It is too early to stick peas yet, but your pigs may require it.—*Pun.*

GROUND VINERIES.

It was in the tenth edition of Mr. Rivers's entertaining and useful little work, the "Miniature Fruit Garden," that the first description of a ground vinery was made public. It then bore the objectionable designation of "Curate's Vinery," which neither indicated anything of its character, nor established between it and curates any necessary relationship. The term "Ground Vinery" is at once descriptive and appropriate, for it consists of a glass frame laid on the ground for the protection of a grape vine which is trained beneath it in immediate contact with the earth. Originally the frame was designed to cover a furrow lined with tiles or slates, the vine being trained along the furrow with the aid of a few sticks laid across to support it, and the bunches of grapes were suspended in the furrow, and derived benefit from the heat reflected upon them from the slates, while the glass above protected them from sudden changes and ungenial weather. Mr. Rivers improved upon the original construction in 1860, by placing a frame on the ground without making a trench for it, simply providing a few slates for the vine to rest upon, and placing bricks a few inches apart to keep the wood of the frame off the ground and allow of ventilation.

The ground vinery has become popular by its merit. Experience proves that this simple and comparatively costless apparatus possesses advantages for the growth of grapes that render it worth the attention of every person desirous of tasting the best of fruit without incurring the expense and labour attendant upon the modes of production usually resorted to prior to the adoption of these vineries. They do not indeed supersede the vinery proper, but as adjuncts they are invaluable, and in the majority of cases where they have been adopted they are substitutes for grape houses, where because of the expense of such structures, grapes of good quality would not be grown at all.

During the past few years these vineries have been improved in various ways, but radically they remain the same as constructed by Mr. Rivers in 1860. They are made in lengths of 7 feet each, and may be so connected as to make vineries of any length that may be desired. The usual width of the frame is 2 feet 6 inches for a single vine, or 3 feet 6 inches for two vines trained side by side under the same roof, 14 in. apart. In order to present to such of our readers as are unacquainted with these structures a clear account of them, we subjoin figures of three separate forms, with a few particulars respecting them.

RIVETT'S BARLESS VINERY.—This is the Rivers form reduced to the extreme simplicity. There is the usual frame, but it is destitute of sash bars, the squares of glass being fixed in their places by means of grooves top and bottom, and putty is used at the bottom only. The squares are placed so as to meet edge to edge; that they should fit exactly is of course not necessary; indeed, there is perhaps some benefit in the way of ventilation derived from the unavoidable absence of an air-tight arrangement. These vineries are made by Mr. Rivett, Railway Bridge, Stratford, Essex. They are usually sent out unglazed, so that there is no risk of damage in transit, but the purchaser may have suitable glass sent with them securely packed, or may have them without glass, and get them glazed as he may see fit. No. 1 is 7 feet long, 2 feet 6 in. wide, 1 foot 3 inches high inside, and costs for woodwork 5s. 6d., and for glass 7s. 6d. No. 2 is intended for two vines; it is 7 ft. long, 3 ft. wide, 1 foot 6 inches high inside; the cost of the woodwork is 6s. 6d.; the glass costs 9s. 6d.; closed ends cost 1s. each. When put to use, the frame rests on a row of bricks, which are simply laid upon the ground at a distance of a foot or less apart, the open spaces between the bricks serving for ventilation.

DENNIS'S PEOPLE'S VINERY.—This is an excellent construction made by Mr. Dennis, the well-known horticultural builder and engineer of Chelmsford, Essex, whose iron plant-houses have quite established the fact that metallic frames are superior to wood in lightness, elegance, and durability, and free from the vices alleged against them in respect of injurious drip and rapid conduction if the houses are properly constructed in the first instance. These vineries are constructed in both wood and iron, the dimensions being the same as above stated, and the prices range from 10s. to 20s. each. They are light, substantial, elegant, and durable.

WELLS'S PORTABLE FOLDING VINERY.—This is a very finished structure, its principal peculiarity being that the two sides are hinged together, and every separate 7 feet length may therefore be folded like a book and carried

under the arm from one part of the garden to another. It will be seen presently that portability is a matter of the highest importance, and that therefore the folding method is not a vain invention. To be sure all these things are portable, and a 7-foot length cannot be a serious matter for removal; but Mr. Wells had in his mind originally to adapt these vineries to two distinct purposes—the growth of grapes in summer, and the protection of such things as cauliflower, lettuce, endive, &c., &c., in winter; and to promote this double use, he made them in such a way that if needful a lady could fold them and carry them with ease. It will be seen by the figures that the ends fold as well as the sides, so that they may not only be carried with little trouble, but may be packed away if needful in a small compass. These vineries are made in the best style possible, and are sent out complete and finished—a 14-foot length, with slates for the bottom, costing £5 10s. for a single vine, and £7 10s. for two vines, with some addition for cases if packed for transit.

It is best to place these vineries so that they stand north-east and south-west, as in this position they obtain a maximum of sunshine. Level ground is to be preferred to trenches, for not only are trenches liable to become filled with water, but they are less beneficial to the fruit than level ground, because when resting on

slates the fruit is subjected to a great degree of heat, the slates becoming so hot in the height of summer that the hand can scarcely be kept upon them more than a few seconds at a time, and it is on hot rocky surfaces that grapes attain perfection in countries where the vine is more at home than here. It would be a still further improvement if instead of placing these frames on common bricks placed a foot apart, they were placed on perforated bricks placed close together, or separated only by a few inches, for then there would still be good ventilation, and rats and other vermin would be excluded. As rats are fond of grapes, this is a consideration of some importance. These vineries may be adopted for the cultivation of vines to any extent that may be desired by the cultivator, and if it is intended to form a large plantation, 7 feet

lengths may be used to begin with, and these may be increased in length as the vines extend, so as to have ultimately rods of 14, 21, or 28 feet in length, or more than that if needful; indeed, we hope yet to see 50 feet rods in such vineries, and it only needs patience to produce them.

In planting it is well to prepare the soil at the end where the roots are to be, so that the vines will be

encouraged to grow freely, but without rankness. A luxurious growth is not to be desired, therefore persons who contemplate burying carcases or loading the border with manure are less likely to obtain good grapes than those who adopt a more reasonable procedure. Sandy or calcareous loam deeply dug and enriched with amoderate dressing of rotten dung, will in most cases suit the requirements of the grape vine. Where the soil is clay or rank gravel, or any other staple not adapted for the vine, a mixture should be prepared consisting of sandy loam three parts, old mortar or lime rubbish one part, and rotten dung one part. Such a mixture, two feet deep on a dry bottom, and half a square yard in superficial extent, will suffice admirably, and ensure a healthy growth without excessive luxuriance.

Supposing vines to be turned out of pots, which is perhaps the best way to begin, all that is needful is to shorten the rods about one-third, and by means of a few pegs to fix them down upon the slates along the centre of the frame. It is not well to allow fruit the first season after planting, but as most people are anxious to derive immediate benefit from their outlay, two or three bunches may be allowed the first season after planting if the canes are ripe and strong when planted. During the season the shoots should be stopped by nipping

out their points so as to secure a regular growth, and in the winter the vines should be closely pruned back, the laterals that have fruited being removed by a cut to the base, leaving an eye there for the next year's crop. If doing well, the vines will always produce three times as many bunches as should be allowed to swell off, therefore thinning is an important matter. Mr. Wells, the inventor of the portable vineries, has had crops of grapes in his own vineries averaging one bunch for every foot length of rod, and samples of those have been exhibited at Guildhall and elsewhere; but that is rather too large a crop for the future well-doing of the vines. The month of March is the best time for planting these vineries, but planting may take place as late as June, and if the early part of the season is lost, planting may be performed in autumn. All

Rivett's Barless Ground Vinery.

Wells's Patent Portable Ground Vinery.

things considered, we should prefer to buy strong young canes in pots, and turn them out carefully into good borders in March. As to cultivation, stopping and thinning have been named as necessary. Should red spider appear, sulphur should be sprinkled on the slates, but as a rule vines in these structures are healthy and vigorous, and pretty well take care of themselves.

To grow grapes, however, is only one of the uses to which these structures may be applied. A very important service may be derived from them by combining with the culture of grapes a system of vegetable or flower culture, so as to turn to account the frames during winter, when the vines are not in need of them. True, it is not well to expose fine rods of grape vines to severe frost, but the advantage to be derived from the use of the frames in winter for the protection of useful esculents, will abundantly repay the little trouble necessary to secure the vinea from injury by means of haybands or a loose covering of clean straw during sharp weather. When the frames are used as suggested during winter, the beds should be laid out to suit them in respect of width, and be planted with such subjects as require protection only without artificial heat. The practical cultivator will see that for cauliflowers, endive, lettuce, sweet herbs, and the hardier kinds of bedding plants, these frames are as well adapted as ordinary box frames or pits; but they may be used also to forward early supplies of saladings, strawberries, and for the protection of the forward rows of peas, until it becomes absolutely necessary to place them over the vines again. In the FLORAL WORLD for June, 1866, we gave a plan to scale for a set of twelve beds of 28 feet length, for which six lengths of frames would be required. Those who are desirous of further information on this part of the subject would do well to refer to that.

In respect of the varieties of grapes adapted for these vineries, the cultivator may make free choice according to his wants and tastes, if careful to avoid such varieties as really require fire-heat. The two varieties which have been found most productive and generally useful are *Black Hamburgh** and *Black Prince*.* The following may be planted with the most reasonable expectation of a gratifying result: *Trentham Black*,* *Golden Frontignan*, *Black Frontignan*, *Primavis Frontignan*.* *Chasselas Rose de Falloux*, *Chasselas Vibert*,* *Chasselas Violet*, *Royal Muscadine*, *Early Black Bordeaux*, *Esperione*,* *Buckland Sweetwater*, *Gros Maroc*. In the foregoing the best six are marked with asterisks. S. H.

A RAPID RUN THROUGH THE VICTORIA NURSERY, HOLLOWAY.

The large conservatory facing the Archway Tavern, in the Highgate Road, is known as the east or principal entrance. It is a noble structure, chiefly filled with the grandest subjects it is possible to keep in a cool house, and is never heated more than is sufficient to keep the plants in health during the winter. Taking the centre walk, the first plants we meet are a pair of handsome palms, *Chamærops humilis*, about 12 feet high, in large tubs; next, a pair of large camellias loaded with buds and flowers. Towering above these is the noble palm *Seaworthia elegans*, about 15 feet high, nearly reaching the roof. At the angles, near the fountain, stand a splendid pair of *Dicksonia antarctica*. To match them on the opposite angles, the finest pair of *Dracæna lineata* in the country; this species is certainly the finest of all the *Dracæna* tribe. Following on the centre walk we come to a splendid pair of orange trees loaded with fruit. Towering above these on one side is that enormous *Dracæna Draco Berhavi* that caused such a sensation at the International last year, and which was so beautifully figured in the GARDENER'S MAGAZINE of June 2, 1866. As a match to this is a *Dracæna indivisa*, about 15 feet high, and at the further angles an unsurpassable pair of *Beaucarneas*, one being *B. recurvata*, the other *B. glauca*.

At the bottom of the steps leading to the shop and offices is a remarkably fine pair of *Dicksonia squarrosa*. This is certainly the most handsome and at the same time most hardy of all the tree ferns. It should be mentioned that with the above are three fine pairs of *Yucca aloifolia variegata*. One of the leading features in the system of embellishment adopted in this house is that all the plants are arranged in pairs as near as possible. This arrangement produces a great effect, without looking in any way formal, and the exact balance of forms right and left gives to the scene a spacious, roomy, and artistic air. The centre is filled up with well-grown specimens of camellias, ferns, azaleas, and such striking subjects as *Araucaria Bidwillii*, *A. excelsa*, *A. Cunninghamii*, *A. Cookii*, and other fine plants, with a number of specimen ferns, such as we see at the exhibition. Worth mentioning here as suitable for a cool conservatory are the following: *Todea Africana**, *Cyathea Smithii*, *Dicksonia antarctica*, *Marattia elegans*, *Polystichum ordinatum*, a very handsome new variety, only just being distributed; *Woodwardia radicans*, a glorious plant, the fronds completely covering the pot, which is a large one; with *Lomaria Gibba*, and many others too numerous to mention.

Taking the right-side platform, we have a marvellous collection of Agaves, Yuccas, Beaucarneas, Dasyliurium, &c., filling the whole side, 100 feet in length. Taking a few of the most remarkable, we find amongst them *Agave schidiigera*, *A. univittata*, *A. medio picta*, *A. aurea variegata*, *A. deabata*, *A. heteracantha longifolia*, *A. filifera longifolia*; *Beaucarnea recurvata*, *B. glauca*, and *B. latifolia*; *Dasyliurium acrotrichum*, *D. glaucum*, *D. latifolium*, *Hechtia Ghiesbreghtii*, *Yucca Stokesii*, 3 feet high: a magnificent pair of these meets the eye on entering the house; *Yucca albo spica*, *Y. canaliculata*, *Y. quadricolor*, and numerous others. It is a most interesting group, and presents a beautiful appearance. The left side platform contains some fine specimens of azaleas that promise well to take a prominent position in our coming exhibitions, also the finest plant in the country of *Phormium tenax variegata*; here too is the noble *Cordyline indivisa*. The *Coccoloba scandens variegata* is here growing most luxuriantly, having already reached over 30 feet, and is covering a large space. The winter temperature of this house is 40° to 45°.

Almost joining the conservatory is the large intermediate house, about 100 feet in length, where the temperature ranges from 45° to 50°, the first part of which is used chiefly for tree ferns, which are doing well, and have a magnificent appearance. Here are some of the largest and tallest stems that have yet been imported, some already making splendid heads. Mixed with these are the following: *Livistonia Jenkinsiana*, spreading about 12 feet in diameter; *Alsophila contaminans*, a very fine new tree-growing fern, the fronds as much as 10 feet in length. But the most remarkable plant in the house is *Cibotium princeps*, which spreads over nearly half the house, with *Dion edule*, and numerous Crotons, Palms, Cycads, &c., &c. The other division contains many fine specimen Azaleas,

and the *Agave schidiigera*, with a flower-spiko above 8 feet in length, the only plant that has yet flowered in this country; *Cycas circinalis*, about 10 feet high, and as much through; *Iandanus reflexa*, with leaves completely covering the pot. Close to this is a range of five houses built upon the same principle, and nearly the same size. The first is filled with ferns, containing some beautiful specimens of *Gleichenia sphegnacea*, *G. flabellata*, and *G. semivestita*, &c.; *Thamnopteris nidus*, a new *Alsophila* not yet named, with many other new ferns not yet offered for sale, with other choice varieties not often met with. The cool end of the house is occupied with the North American pitcher plants (*Sarracenia*), some very fine specimens; the Australian Flytrap (*Dionæa*), Sundews (*Drosera*), and many other novelties seldom seen. The second is occupied with New Holland plants, chiefly consisting of *Dracophyllums*, *Hederomas*, *Phenocomas*, *Apheloxes*, *Eriostemon*, *Chorozemas*, *Ericas*, and many sorts, a large proportion of them showing well for flower. The third is called the cool orchid house, where the temperature ranges from 50° to 60° during winter, and contains many scarce varieties of *Lælia*, *Cattleya*, *Lycaste*, *Odontoglossum*, and other orchids suitable for that temperature. The fourth is called the East India house, where the temperature is from 60° to 70°, and contains some very fine specimens of *Angræcum sesquipedale*, *A. eburneum superbum*, *A. e. virgineum*, now full of flower, *Vanda Lowii* and *V. suavis*, and *Acrides Larpentei*, *A. quinquevulverum*, and others; also several *Phalænopsis*—indeed all of the leading kinds for which Mr. B. S. Williams is so much noted. The fifth house contains all the best exhibition plants, such as *Crotons*, *Allamandas*, *Dipladenias*, *Combretums*, *Bougainvilleas*, *Alocasia metallica*, *A. Lowii*, *A. zebrina*, with *Ixoras* of different sizes, *Cyanophyllums*, and a large stock of *Dipladenia ambilis*, the best stove flowering plant that has been introduced of late.

This brings us on to the Junction Road department, where the houses are somewhat small, and well adapted for bringing on young stock. The first is filled chiefly with *Staticea* and some of the new *Azaleas* that have been sent out during the past year, also the collection of new *acubas*. We must not pass over an entirely new plant that took a first prize at the International; it is commonly called a tree violet, but is in reality a full branching shrub which grows about five to six feet high, covered with violet-scented flowers. The name of this plant is *Tinnæa Ethiopica*. This department consists of nine houses filled with hard-wooded plants—with *Geraniums*, *Cinerarias*, *Calceolarias*, *Primulas*, &c. In other houses are collections of pines and vines; these are now being started for the season's growth.

Two ornamental conservatories facing the Junction Road are occupied with specimen *Azaleas*, *Eriostemonas*, *Pieromas*, *Rhododendrons*, &c., which are well coming on for bloom. These when arranged with foliage plants will make the Victoria Nursery worth a visit when they are in bloom, though indeed it is full of attractions at every season of the year. It is well to mention that Mr. B. S. Williams is his own architect and builder, and purposes carrying on that branch of business in connection with the nursery department—an advantage I have no doubt many will avail themselves of.

I wish now to thank the several heads of departments for their obliging civility and readiness to communicate information respecting the collections in their care. I called merely to buy a few plants, and at the same time have a look round, but as I made notes as I went on, I have been enabled to construct the foregoing sketch of the place and its principal features, which I hope will be not altogether unfit for the pages of the GARDENER'S MAGAZINE. E. R. T. (an exhibitor).

LESSONS IN BOTANY.—No. VIII.

CLASSIFICATION.

Having now considered the various parts which go to form a complete plant, it will be well to say a few words concerning classification—a subject we are now in a position to understand, which before we could not hope to do, for it is useless to judge of the whole until we have contemplated its parts throughout: as well might we attempt to form an opinion of the human frame from seeing a man's head thrust out of a coach window.

Very little was done towards completing a system of classification until Linnæus undertook the task. Tournefort had indeed published a scheme which was founded on the corolla; but it is at once evident that a part so variable and so fugitive is very ill-fitted to found a permanent arrangement upon.

Linnæus therefore is commonly called the father of botany, and he well deserves the title on account of the magnitude of his discoveries and his labours, by which he succeeded in reducing to form and method what was before "audis indigestaque moles," although he has undoubtedly left much, very much, to be done by his successors.

In fact, it may be truly said that even at the present day no adequate arrangement of plants has been made, notwithstanding the numerous and ingenious attempts of such men as De Jussieu, De Candolle, and Lindley.

But to return to Linnæus: He was the first to establish the theory of the sexes of plants, corresponding to the male and female sexes of the animal kingdom, with this difference, however—that in vegetables the male and female organs of reproduction are usually found in the same individual.

Thus in the rose the stamens are the male organs, the pistils the female; and as we have seen it is by the fecundating pollen emitted by the former, and caught and absorbed by the latter, that the seeds are fertilised. Starting with this fact, Linnæus built up his great artificial system, as it is now called, of which we shall proceed to give an outline, premising that until within the last thirty years it was in universal use among English botanists, and was improved and adorned by the labours and writings of such men as Sir J. E. Smith and Dr. Withering.

Even now this system remains unrivalled for the facility it affords for classing and finding the name of an unknown plant; but the constantly increasing number of exotics discovered with every year has rendered a more elastic arrangement necessary.

By the Linnæan system all plants are divided into two great divisions, the flowering and the flowerless; or as they are technically termed—(1) Phenogamous; (2) Cryptogamous.

The first division includes the great majority of plants of British growth (with which we are more immediately concerned), from the lovely rose down to the small parasitic dodder, and from the lordly oak to the meanest grass in our pastures.

The second division consists of ferns, lichens, fungi, &c. We shall first, as in duty bound, speak of the flowering plants. They are subdivided

into twenty-three classes, of which the first eleven are distinguished solely by the number of stamens in each blossom, thus:—

1. Monandria	One stamen in each flower.
2. Diandria	Two " "
3. Triandria	Three " "
4. Tetrandria	Four " "
5. Pentandria	Five " "
6. Hexandria	Six " "
7. Heptandria	Seven " "
8. Octandria	Eight " "
9. Enneandria	Nine " "
10. Decandria	Ten " "
11. Dodecandria	From twelve to twenty stamens in each flower.

These names must be committed to memory, and to assist in this operation we will explain their meaning for such as are ignorant of Greek (all of them being taken from that language); for it is much easier to remember a term with some definite idea attached to it, than a mere meaningless symbol.

We observe in the first place that the termination "andria" is common to the whole eleven: it is the Anglicised form of the Greek word *ανδρως* = andros, meaning a man, and is in allusion to the stamens, which we have explained are the male organs of the plant. The prefixes "mon," "di," &c., simply indicate the number in each flower, being the Greek words for one, two, &c.; so that "mon-andria" means "one man" (or stamen); "di-andria," "two men," &c.

A person totally unacquainted with the Greek language may find these names rather difficult to remember; a good way to aid him to retain them is to find a real or fancied resemblance to their English equivalents. Thus by a considerable stretch of the imagination, we may perhaps detect a likeness between "(m)on" and "or(e)," "tri" and "t(h)ree," "hex" and "six," "oct" and "eight," while "hept" occurs in heptarchy, "pent" in pentateuch, &c.

The twelfth and thirteenth classes are distinguished by the manner in which the stamens are inserted.

12. Icosandria Twenty or more stamens inserted into the calyx.
13. Polyandria Twenty or more stamens inserted into the receptacle.

The general features of these two classes are very similar, therefore this distinction should be borne in mind, for it is important—the Icosandrian plants being as a rule extremely valuable and wholesome, furnishing such treasures as the pear, apple, peach, plum, strawberry, raspberry, rose, and many more; while the Polyandrians are often very poisonous, and generally acrid and unwholesome; for instance, the wolfsbane (or monkshood), baneberry, hellebore, and buttercup.

In order to guard against possibility of mistake, we would remind the learner that the receptacle is the top of the flower-stalk, and that in Polyandrian plants the stamens are so inserted on it that the petals and sepals may be pulled off one by one without disturbing them; take a buttercup and try; whereas in the Icosandrians the stamens are inserted into the calyx, which cannot be removed without removing them also. Examine the hawthorn, and you will see this at once. And in this place we will again impress upon the reader what we have already laid down—namely, that he should always apply the principles he may learn to practice: they are no good without. Thus he should find out plants in each class as it is given (when possible), and examine their structure thoroughly.

The prefixes "icos" and "poly," we should explain, mean "twenty" and "many" respectively; "andria" has been explained before.

E. R. V. SHUTTE.

ON PLANTING TREES AND SHRUBS.

A tree is a most beautiful object, often more admired than the most costly building near which it has been planted; its coat may have been a farthing, a few pence, or shillings, and often with no additional expense, but only the allowance of sufficient room to develop its proper natural proportions, it may live fifty, or one hundred years, or more, and during that time he not only an ornament, give an appearance of increased value to the place, and be a source of joy to the owner, his family, and other residents and visitors of the place or neighbourhood, but improve the general effect of the scenery, and be a protection from cold winds, and where planted in sufficient masses, renders a neighbourhood, otherwise barren, poor, and bleak, in appearance as well as in reality, comparatively warm, habitable, and rich. Considering the small amount of labour and expense, and which in most cases is more than repaid in the value of the timber, time and money can scarcely be spent to greater advantage than in following the advice, "Always be planting a tree."

Near the bulk of houses in such places as Manchester, even where erected at great expense, the ground is necessarily much limited, and as no great number or extent of plants can be used, there is no true economy in sparing any reasonable expense in these being the best, sufficiently hardy for the purpose, as a dozen large evergreens from 6 to 10 feet high, costing as many guineas, may make the difference between a place having a poor and rich appearance, and its being not only more beautiful, homely, and enjoyable, but when required to be let, would often make the difference of as much extra rent being received ANNUALLY as the whole of the extra tree had cost. Compared with building and indoor decoration, shrubs are comparatively cheap; yet the first impression on entering a place, and the only one in passing, is received from the garden; and if it be well or poorly furnished, the remainder is generally considered accordingly. Large evergreens may be had for such purposes, regularly shifted every two years, so as to move with perfect safety.

In moderate sized places where no great breadth or quantity of plants can be used, the plants if ever so few should be well selected, of sorts that will do well in the place, as a common thing in health is better than a fine one sickly; and even then the effect in the end will depend almost entirely on the taste used in arranging them, as the colours used by a painter may make a mere daub, or a beautiful picture. In many cases where great pains are taken with arrangement of colours of bedding plants, no attention whatever is paid to the general effect of the entire garden, park, or general scenery about the place, while if a few (not too many) trees were planted here and there to give variety of colour, of such sorts as purple leaved varieties of beech, sycamore, horse chestnut, elm, holly, hazel, &c., the variegated maple, sycamore, and Turkey oak, the white-

leaved poplar, willow, *Pyrus salicifolia*, *Shepherdia argentea*, and the red-brided thorn, area, mountain ash, red and yellow-barked willows and dogwood, common or variegated ivy and Virginian creeper, climbing up trunks of trees, and many other such effective things, they wonderfully and permanently improve the general appearance of the place with one comparatively insignificant outlay, while endless care and expense is bestowed fresh every season on a few flower-beds, which, compared with the above, are often mere details worth comparatively little notice.

In laying out and planting clumps and belts for ornament in places of limited extent, care should be taken that the ground is not wasted, and the appearance of extent diminished, by making them too broad or their covering too much surface. Generally 5 to 10 feet is sufficient if planted thickly with young plants, and leaves more room for grass, giving the place a lighter, more airy, and elegant appearance than if crowded and darkened by being overdone with too much cover. Where large surfaces of grass require relief, it may be done with a few good single specimens, clumps of evergreens, or beds of flowering plants, always remembering that, except sufficiently roomy walks, no bare ground should be seen that can be avoided. Many places are spoiled by having two or three times as much surface covered with trees as they ought to have. To fill the ground well, care should be taken to prevent hedges, trees, or shrubs becoming top-heavy, causing the shade and drip from the higher branches to kill the lower, leaving the ground bare at the bottom; so that it is best while the plants are young (though by no means making them formal, but rather allowing the trees sooner or later to grow in their natural form), to prune all more or less in a conical shape by repeatedly pinching, during summer, with the finger and thumb, several times if required, or cutting in the branches gradually closer near the top, and leaving the lower longer, so that every part of the plant can have equal light, air, and rain, thus keeping the ground covered, and every part of the plant equally furnished with good healthy well-ripened wood, leaves, and flowers. This applies equally whether clipping a hedge, training a hardy shrub or fruit tree, or the choicest greenhouse or stove plant, and enables the cultivator to grow three or four times as many healthy leaves and flowers in a certain space as could be done with loose, broad, flat, or irregular heads. Where the plants have been much neglected, and become thin or bad in shape, a portion of the worst branches may be shortened in one season, which may break during the following summer, and the remainder may then be cut in the winter following. In arranging plants that are distinct in form or colour, in an irregular English garden, they should be distributed at very unequal distances, and in groups of unequal quantities, so that one thing may prevail in one part and another in another; as if planted at equal distances, the different parts of the garden, whether the place be large or small, would be only repetitions of the first few yards planted. Dark purple colours should be used very sparingly, or they give a dark sombre appearance to a place.

Where beds have, during the summer, been filled with bedding plants, to avoid their being bare during winter, small dwarf evergreen shrubs may be planted in autumn and removed in May to some convenient place, and, being regularly shifted, would not suffer with being removed.

The instructions given for planting fruit trees will apply equally to these. Those marked (peat) may be planted in a mixture of about four parts peat, one sand, one well-rotted manure, and one of rotten leaves if they can be easily procured.

Forest trees may be transplanted from middle of October till middle of April, avoiding frosty weather, or exposing the roots to frost, or allowing the roots to get dried (especially beech, birch, Scotch and Austrian pines), cutting clean the ends of any bruised roots, otherwise reducing them as little as possible, as if much reduced the head would require shortening or thinning in similar proportion. For immediate effect, a small proportion of large sizes are in some cases indispensable; for such purposes a quantity are kept regularly transplanted, but in all cases the bulk should not exceed 5 to 6 feet, and in exposed bleak situations only 3 to 5 feet. Beyond this, though forest trees generally require only an ordinary soil that may be on the ground, money would be better spent in making an extra preparation of the soil by deep trenching, breaking and manuring the soil well, and in a few years would produce heavier healthier trees at a much less cost than if all were planted large and requiring stakes. In smoky places a good preparation should be made, so as to assist the plants as far as possible. A statute acre, with plants 3 feet apart, requires 4,840 plants; 3½ feet, 3,556; 4 feet, 2,722; 4½ feet, 2,151.

Evergreens move best at any time of the year when the ground is warm, the bottom-heat causing the roots to commence growing immediately, though of course they cannot be moved when the growth is soft and young, as there is great risk at that time of dry weather killing the young growth; but as soon as the wood is tolerably ripe, which of some things is about the end of July, if settled wet weather can be depended on for a few days, they move well then, but as there is risk during all summer months of drought, they are best planted during September, October, November, April, and May; but plants that carry large balls, like rhododendrons, as most evergreens on this ground do, may be moved at any time in favourable weather. Great care should be taken with all evergreens not to have the roots dried any more than can be avoided, especially hollies and conifers, avoiding planting in frosty and droughty weather.

In moving large evergreens that take up with few or bad roots, and especially in droughty weather, the head should be thinned out, and reduced to a skeleton, or even a stump, if the root is so bad as to be able to carry no more, and may be cut into good shape or otherwise reduced at once, so that the root may have no more to support than it can do safely; it should be planted in good soil pressed firmly to the root, the plant staked if required, and mulched with a little littery stable dung, have one thorough good soaking of water, and if very dry, mats over the plants, and let the plants be syringed in the evening to prevent evaporation from the leaves. This is preferable to much watering near the roots, which when mutilated and dried have less power than usual to take up much moisture, and continual watering in such cases only sours the soil and kills the roots. The ground is cold to move evergreens during the months of December, January, February, and March, though when not frosty, as there is no risk of drought, nor much evaporation, the bulk of evergreens do well enough moved then, and it enables the planting to be done with forest trees, roses, &c., the leaves of which shrivel if moved too early in the autumn.

Deciduous trees require little preparation, if the soil is fresh and good.—*Catalogue of Forest Fruit Trees*; SAMUEL STAFFORD, Hyde, Manchester.

New Plants.

The following have lately been figured and described in the BOTANICAL MAGAZINE:—

Brachystelma Barberic.—A curious member of the natural order Asclepiadæ, which abounds in curiosities. It is a native of Kaffirland, growing in dry places, and is used as an article of food by the natives. The root is a depressed tuber as large as a turnip, the leaves three or four inches long, linear-oblong and spreading. The flowers are collected into a dense globose head, four or five inches in diameter, dingy purple speckled with yellow. The lobes of the corolla terminate in slender tails one inch long, which arch inwards and cohere over the centre of the flower, so that the appearance is that of a globe covered with a delicate and elaborate network.

Nierembergia rivalaris.—A pretty species from La Plata, introduced by Messrs. Veitch. It is of slender, creeping habit, abundantly branched; leaves variable, spatulate; flowers an inch and a half across, white with a yellowish tinge.

Notylia bicolor.—This orchid is a perfect gem. It was first discovered in Guatemala by Mr. Skinner, and has been established at Knypersley for more than twenty years on a small branch of the Cork-tree Oak, on which it never fails to flower profusely in the autumn. The whole plant is usually not more than an inch and a half high; leaves generally five; flower-spikes drooping and graceful, bearing from ten to twenty elegant little flowers, the sepals white, petals lilac, with blue spots towards the base.

Glyphæa monteiroi.—A tropical African shrub, belonging to the natural order Ylacææ. The leaves are four to six inches long, ovate, and toothed; the flowers an inch and a quarter in diameter, bright yellow.

Vanda Bensoni.—An elegant species from Rangoon, sent to Messrs. Veitch by Colonel Benson, and flowered at Chelsea in the summer of 1866. The spikes are upwards of half a yard long. It differs from *V. Roxburghii* and *V. concolor* chiefly in the absence of tessellation, and in the inside of the flowers being richly spotted.

Cypella carulca.—This magnificent Irid was sent to Kew from Bahia by Mr. Williams. The flowers are four inches in diameter; the colour rich blue; claw yellow, with orange bands.

Heliconia humilis.—A superb musaceous plant, a native of Guiana, where it abounds in marshy places. It has a tuberous rhizome, is destitute of a stem, the leaves being all radical; petioles two to three feet long; blade one to two feet long. The scape rises in the midst of the leaves, and consists of about four distichous spathe of a brilliant scarlet colour, each spathe producing five or six flowers, which are of secondary importance, as respects the beauty of the plant.

Cypripedium Schlimii.—A pretty species from New Granada. It blooms in the late summer and autumn months, producing six or more flowers in a scape. The flowers are elegantly spotted crimson on a white ground; the lip has a large blotch of crimson in front.

Heliotropium convolvulaceum.—A beautiful American annual, introduced by Mr. W. Thompson, of Ipswich. The leaves are long, the flowers large, convolvulus shaped, and white with faint shades of blue; very sweet-scented, and opening towards sunset.

Lycaste gigantea.—A stately species of the best of its race with the exception of *L. Skinneri*. The flowers are of great size; the sepals and petals a warm yellowish-olive hue; lip three-lobed rich maroon, with a narrow orange rim.

Combretum micropetalum.—A magnificent climber from Brazil. The leaves are opposite, usually oblong; racemes spreading; flowers densely crowded; petals very minute; stamens three quarters of an inch long, yellow, with orange anthers, each raceme presenting the appearance of a golden brush.

Cattleya Dowiana.—A superb species, and discovered in Costa Rica by Warszewicz, originally and lately rediscovered by M. Arce, and transferred to Messrs. Veitch, in whose establishment at Chelsea it flowered in 1865. The pseudo-bulbs are eight inches to a foot high; leaves one on each pseudo-bulb, from a span to a foot long. Peduncle two to six flowered, very stout; flowers very large and beautiful, nankeen coloured, with the exception of the lip, which is dark purple streaked with gold threads. A fine figure of this gorgeous Cattleya.

Bowiea volubilis.—This is one of the most curious plants ever introduced into Europe, and is perfectly new to science. It consists of a fleshy green bulb, from the apex of which ascends yearly a very slender twining flower-stem six to eight feet high that throws out an abundance of flowerless branches, and above bears numerous small green flowers. Leaves it has none.

Curcuma Australasica.—Introduced by Mr. John Veitch from Cape York, Australia, and flowered in tropical stoves both at Kew and Chelsea last year. Leaves a foot to a foot and a half long, lanceolate; the spike five to seven inches long, many flowered, the most conspicuous of its features being its many rosy-tinted bracts.

Helianthemum ocyroides.—A most beautiful hardy rock rose, native of Spain and Portugal. It is of light and graceful habit, and produces an abundance of flowers, which are the size of a florin, gold-yellow with chocolate-coloured disc.

Grias cauliflora.—A curious and interesting myrtaceous plant, much esteemed in the West Indies as the "Anchovy Pear." It is a tree twenty to fifty feet high, the leaves crowded at the ends of the branches, spreading and drooping, three to four feet long, ten inches broad, dark green and shining. Flowers produced on the trunk of the tree, far below the leaves, on stout branching peduncles; they are two inches broad, pale yellow, very fragrant. A fine palm-like plant requiring the stove, easily managed and highly ornamental.

The following are figured and described in recent issues of L'ILLUSTRATION HORTICOLE:—

Alnus glutinosus, v. aurca.—A finely variegated alder, the leaves richly marked with alternate bars of dull green and yellow, calculated to produce a striking effect in plantations and shrubberies.

Rhododendron Archiduc Etienne.—This beautiful hybrid has superb dark green foliage and large flower-heads; the flowers whitish, and heavily spotted with crimson, chocolate, and red.

Liliputian Chrysanthemums.—A group comprising *Dona carmen*, white; *Soliman*, orange-red; *Aminata*, fiery-red, and yellow tips; *Damiette*, purple, and maroon tips; *Zelitz*, rosy-lilac, the petals striped white; *Lucinda*,

sulphur and white; *Rosabelle*, a large flower (for a liliputian), the outer parts rosy-blush, shading to white in the centre.

Saccolabium curvifolium.—A good figure of this well-known species, which is much and justly valued for its beautiful orange-red flowers.

Pear Bourré de Promentel.—Described as a richly flavoured melting pear which is fit for use in October and November. It is of large size, pyriform, yellow, much covered with russet.

Weigelia Middendorffiana.—A superb hardy shrub, the flowers of which are produced in numerous clusters, the colour deep red with shades of black in the centre.

Promontia Californica.—A fine Californian shrub, which Dr. Hooker has described as one of the choicest things of the kind introduced of late years. It belongs to the natural order Malvaceæ, and has flowers that do not greatly differ from the type of the order; they are yellow with reddish-orange stamens.

Kempferia Roscoana.—One of the many long-known inhabitants of our stoves that have acquired new importance of late owing to the increasing passion for beautiful leaves, which in this plant are richly coloured with pale green crescentic marks on a blackish-green ground. The flowers are white, and are produced one at a time.

Amaryllis (Hippeastrum) Alberti.—A double-flowered Hippeastrum, with very showy flowers, the segments of which are deeply lobed and notched, the colour lively red.

Rhaphia tedigera.—A Brazilian palm of noble aspect, attaining to a considerable height; the stem cylindrical, and crowned with a spreading tuft of cycas-like leaves.

Myosotis Imperatrice Elizabeth.—This is an exquisitely beautiful hybrid, believed to be between *M. azorica* and *M. alpestris*. The flowers are deep blue with orange-coloured eye, produced in dense bunches, and presenting a most charming appearance. If any plant deserves to be likened to jeweller's work, this does, for its flowers are like torquises. The increasing taste for hardy herbaceous plants may be expected to create a demand for this plant when it becomes known, and it certainly deserves a place in every garden in Britain.

Strawberry Perpetual Pine.—A variety described as of great value for its beautiful and highly flavoured fruit, which is produced abundantly in autumn.

Camellia Stella Polare.—Small and neat; colour-rosy carmine, every petal marked with a central pale bar. The colouring and form alike symmetrical, and the flower highly finished.

Calendar.

WORK FOR WEEK COMMENCING FEBRUARY 2.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—There should be no delay in getting ready every inch of ground intended for summer crops. We shall probably have an early spring, and it will be well to risk a little more than usual in early sowings of crops that come in quick, as in the event of late frosts protective measures may be resorted to, and the loss of seeds is not a great matter compared with the probability of extra early produce. Get all plots requiring manure ready at once, as it is much better to have the ground prepared in advance, that the manure may be more completely incorporated with the soil, than to sow or plant immediately after manuring. Ground for peas, beans, onions, cauliflowers, and broccoli must be liberally manured and deeply stirred. Mark out the soil for onions into four-foot beds, and raise the beds six inches above the general level, and leave the surface rough. At sowing time the surface will be nicely pulverized through exposure to the air, and the seed can be sown clean and rolled in firm, which is not always possible where the ground is in a pasty condition, or has been but recently made ready. Choose for potatoes ground on which cabbage, or broccoli, or celery has been grown, and which for those crops was well manured last year. Make up sloping borders under warm walls and fences for early lettuce, radish, onion, horn carrot, and to prick out cauliflower and broccoli from seed-pans, &c. On dry soils plant potatoes as soon as possible; sets should be of moderate size, and with short, stubby, hard sprouts upon them; when the sprouts are long and white it is scarcely reasonable to expect a sound and plentiful production. On wet soils it will best to defer planting the main crop till next month. To raise a few early potatoes, the simplest method is to make up a slight hotbed, and cover it with old lights, or canvas on hoops, or even hurdles or mats will do, as by the time the haulm appears the season will be sufficiently advanced to allow of taking off the covering by day, putting it on at night, however, to keep safe from frost. If there is plenty of charred refuse, use it liberally in making up the bed, and cover the sets with some of it reserved for the purpose. The main crop of potatoes should be planted at greater distances between the rows than is usually allowed; 2½ feet apart and 9 inches between the sets should be the least distance for moderate growers, and 3 feet apart and 1 foot or more between the sets for robust growers. When growers complain that their potatoes have "run all to haulm," it may always be understood that they are planted about twice as thick as they ought to be.

ASPARAGUS.—The beds should be lined, if the heat is declining; the heat ought to be near 60° to ensure a quick growth of eatable shoots. Ground for new beds should be got ready at once, and tolerably manured.

CAULIFLOWERS to be sown in boxes, and placed in gentle heat. It is quite worth while to pot them and give them good frame treatment, as with a well-prepared soil made rich with manure in which to plant them, large handsome heads may be obtained early in the season, when they will be worth three times as much as those that come from sowings on warm borders.

CELERY must really be sown now by all who want a reasonably early supply; in fact, for the first main crop. The seed will soon sprout now if sown in pans and boxes, and put in some odd corner of the greenhouse or forcing pit.

RHUBARB may be forwarded by covering the stools with boxes, casks, sealable pots, &c., without fermenting material, but the latter will pay for its cost in an earlier supply, and the benefit of the crop by forking it in when the heat is spent. Choose fine dry weather for sowing seed.

LETTUCE.—To ensure an early supply of well-hearted plants, those now up in boxes must be planted out in a moderate hotbed, so as to keep them growing, and fit for planting out on sheltered borders in a month or six

weeks' time. They will then lift with good balls, and if aided by a little shelter, and cared for on frosty nights, will turn in when lettuces are valuable, and will be good. But if the young plants are allowed to stifle each other, and get drawn in the seed boxes, they will never make fine plants, do what you will with them.

POTATOES.—Whole potatoes are preferable to cut sets for planting at this season of the year. Cut sets may be used in April or May, because vegetation is then more active, and a set containing one or two eyes will make a plant directly. Potatoes always grow better, and come to maturity sooner, if the sets are sprouted before planting. Long white flexible sprouts are almost useless—perhaps injurious, because such of them as do not get broken in planting are so debilitated as to be scarcely capable of making a good plant. But short, stout, hard green or purplish sprouts, with a frill of roots around them, grow with vigour from the first. The best way to deal with the seed is to allow it to make sprouts about an inch long (not more) in the dark, and then carefully spread them on the floor, or in baskets, or on a shelf, *in full daylight*. They ought not to be more than two deep, and if laid singly all the better. Exposure to light will cause the sprouts to form chlorophylle, which is essential to healthy growth, and the short green or purplish sprouts will be so hard as to bear reasonable handling without breaking. In planting potatoes, it is a good rule to trench them in; or, as the land ought to be already laid up in ridges, the planting will consist in laying the sets in a trench, and throwing soil upon them from the ridges on each side. From the present time to the end of March is the best for spring planting: autumn planting has its advantages, but is seldom practised; but late spring planting—say after the end of March—is to be avoided as much as possible. It is so important, however, that the ground should be in a sweet condition, that a delay of a week or two is always to be preferred to planting while the soil is very wet or frozen, or before it has been deeply stirred, and for some time exposed to the atmosphere in a rough state to sweeten. To manure for potatoes is, in a general sense, objectionable; but if the ground is poor, it must be done, in which case let there be sufficient laid on and thoroughly well dug in some time before planting. Where a proper rotation of crops is followed, the ground best adapted for potatoes is where celery, cauliflowers, and other crops for which manure was liberally applied, were grown last year. There are three rules to be observed in view of the possibility of disease—viz., choose sorts that ripen early, plant them early, and take them up early. The early bird gets the worm, but the early potato does not take the disease; it usually appears with fogs, heavy rains, and thunderstorms late in the autumn, by which time potatoes should be, not in the ground, but in the store, and the ground again dug for winter greens.

PLANT potatoes, garlic, shallot, chives, onions for seed.

Sow in the open quarters cabbages, peas, beans, parsnips, spinach, leeks. Sow on warm slopes radish, hardy lettuce, cabbage, parsley. Sow in heat, to transplant, Spanish and Portugal onions, cos and cabbage lettuce, celery, tomatoes, capsicum, melon, cucumber, cauliflower, sweet basil, sweet marjoram.

WET GROUND.—Keep off it; every footmark is mischief. Do not allow cattle to poach on any ground that is to be sown or planted with any kind of kitchen crops.

OUTDOOR WORK.—Whatever arrears of winter work remain must now be cleared up, or the consequences will be serious. Finish all pruning, nailing, forking of borders, and planting of fruit trees and bushes. Make quickly a thorough clearance of the vegetable quarters, plant all the old stumps of cabbage, kale, &c., close together, to furnish a few sprouts. Roll and dress up grassplots, sowing seed in bare places, and edging off the margins next the walks and borders, so that the garden may have a neat and tidy look. To keep frost from newly-planted roses, &c., mulch about them lightly with long dung, or draw the earth round them with the fork; loose soil admits less frost than that which is trodden hard.

Flower Garden.

FLOWER GARDEN.—Do not be in haste to fork over the borders that are stocked with hardy herbaceous plants, unless their places are marked. Such things as Pæonies, Campanulas, &c., &c., are destroyed wholesale every season by the ruthless manner in which borders are dug while the plants are invisible, or nearly so. But as soon as they begin to peep through, make all clean and tidy, and sow any hardy annuals that are required. But if the sowing of these is deferred till next month, there will be very little time lost; it is always best to make sure that seeds will grow than run the risk that they will not. Herbaceous plants of all kinds may be planted, and if a little dry chippy manure is thrown over their crowns after planting, it will be a great assistance in case of severe weather. When they begin to grow they will push through it easily enough. Look over

ALPINE AURICULAS.—Sow the seed of these on nice friable soil, already well moistened, and lay squares of glass over the pans so that no more watering will be necessary till the plants are up. If in heat, it should be very gentle, though a cold frame is sufficient.

ALPINES are apt to suffer at this time of year from damp; the frequent roving of frames to keep out frost causes confinement and darkness, and these plants—formed to breathe the purest mountain air—will be sure to suffer unless great care is taken. Where alpine are grown in any quantity, the stock should now be locked over, labels should be rewritten if required, and many of the kinds will require repotting, dividing, or planting out. Keep the store plants in frames very clean, removing dead leaves, and admit as much air as possible. Generally, alpine plants, though very susceptible to the influence of damp, ought never to be dust-dry; water must be given occasionally even during winter.

AURICULAS.—Water gradually as they show signs of growth, and top-dress the pots with well-decayed cowdung. Give plenty of air, and beware of damp. As Auriculas are forward this season, they will require extra care in the event of late frosts. This is a good time to sow seed.

ANNUALS FOR SPECIMENS AND BEDDING-OUT to be sown now, include Balsams, Cockscombs, Globe Amaranths, Portulacas, Schizanthuses, Phloxes (don't forget Phlox Drummondii Radowitz), Brachycomas, Stocks, Tropæolums, Cobæas, Lophospermums, and Aeroelinium. It is too early yet for Asters. First-class annuals should be grown with care, the plants be pricked out early and stopped; if they once get drawn, they never bloom satisfactorily or show their full capabilities. Any that are wanted in large quantities had best, to make sure, be sown in pans also, and placed in a pit.

BEDDING PLANTS may be propagated rapidly by making a sweet hothed to forward plants for cuttings, and to strike cuttings of such as are fit to cut from in the greenhouse. Sow in pans, and place on gentle heat, Salvia

patens and Lobelia speciosa. These come true from seed, and make capital plants for bedding. Cuttings already rooted to be potted off and helped on by a sweet moist heat. If any outbreak of mildew, increase the heat and promote a dry atmosphere; at the same time dust the plants with sulphur or fine peat dust.

CARNATIONS AND PICOTEES.—Put out the whole stock of Carnations, Picotees, and Pinks in the first warm shower we have, and defer watering them as long as will be safe to do so, in order that they may derive full benefit from the rain. Keep the plants hardy, and make ready for repotting. Turn over the compost intended for them, and make careful search for wireworm.

COLD FRAME.—Remove all dead leaves; keep the shelves or plunging material moderately dry; give air as often as possible. Tender plants that have been wintered in cold frames must have very little water at present; they may be growing in consequence of the mildness of the weather, yet as frosts may visit us, much moisture at the root will render them miffy, and losses may occur. But nothing should be allowed to get dust-dry; it is most injurious. Ferns may have water freely if well drained. the rockeries, and take note of what deaths have occurred.

HARDY ANNUALS to be sown in pans to get them forward for planting out. Californian annuals, such as Clarkias, Godetias, Escholtzias, Viscarias, Nemophilas, Candytufts, &c., may be sown in the borders where they are to bloom.

HOLLYHOCKS may be increased from cuttings in a gentle heat, and seeds of choice kinds may be sown with others in a warm pit or cold frame. Get the stations ready for those to be planted out this spring. Dig deep, and manure well with rotted cowdung.

RANUNCULUSES AND ANEMONES must be planted this month, if not planted already. Get them in if possible before the 20th. The soil should be deeply broken and abundantly manured with cowdung. In planting, draw shallow trenches three inches deep and six inches apart. In these place an inch of sharp sand or clean coal ashes, and lay the roots on the ashes—the Ranunculuses with their *claws downwards*, and four inches apart. Sprinkle sand or coal ashes on them, and then cover with an inch and a half of soil.

ROSES may still be planted. Bushes from which flowers are to be cut for show should be planted in firm loam, well manured with turf and half-rotten dung. Dwarf-growing varieties of tender habit which are useful for the front lines of roseries, require an admixture of sand and leaf-mould, or peat, to lighten the soil and promote the formation of an abundance of fibres.

STOCKS.—If any delay has occurred in securing stocks for working, get them in at once—briers for standard Roses, Manettis for dwarfs, quinces for pears, &c. Pot a lot of brier suckers for budding with choice Roses for greenhouse culture, and pot also a few young privets, with one clean stem each, to work Oleas on.

TULIPS.—Protect from heavy rains and severe frosts, but never leave the coverings on one hour more than needful, for they never bloom well if made tender. When the foliage shows regularly over the bed, stir the surface between the rows with a small three-tined fork.

Fruit Garden and Orchard House.

FRUIT GARDEN.—Trees and bushes lifted with care and replanted quickly will carry their fruit pretty well hereafter, but it is late for all trees in bearing to be moved; where, however, it has not been possible to complete operations, there is still good time to plant fruit trees, because even if they produce little this season, they will gain a season's growth on the ground, and that is so much gain. Let all pruning be completed quickly; mulch trees newly planted; prepare scions for grafting, and heel them in till wanted. Get protecting materials ready for wall trees that are likely to require it. Judicious protecting will always pay for the trouble and outlay it occasions.

ORCHARD HOUSE.—Peaches and other orchard house trees will set their fruit more freely if there is a good breeze through the house every day; the atmosphere at the same time to be kept as dry as possible. Peaches to be thinned and disbudded judiciously; do not remove all the superfluous fruit and shoots at once. Trees that have set their fruit to have liberal syringings with soft water of the temperature of the house. Figs setting fruit to be kept in a rather dry air, but with sufficient moisture at the root.

PEACHES.—Supposing a second house to be started now, the first essential will be to see that the roots are well soaked, the wood clean, and all training complete. As the trees begin to push, use the syringe freely, but discontinue the syringe when they begin to flower. In peach houses where a crop is set, thinning will be an important matter. In the process of stoning the trees thin themselves considerably, so the cultivator need not remove all surplus fruit at once; where there is room for a hundred, he may safely for the present leave a hundred and fifty, and such of the extra fifty as pass through the stoning period must be removed afterwards. To use liquid manure at this early stage in the growth of the crop is most injurious; yet it is sometimes done, and there is immediately afterwards a cry out that in spite of the best management the trees will cast their fruit.

VINERY.—Where the vines are breaking, promote a moist state of the atmosphere; this is favourable to a healthy leaf growth, and on that will chiefly depend the quantity and quality of the produce. Vines coming into bloom to be kept rather dry. Vines not yet started may be greatly assisted by making up a bed of fermenting dung in the middle of the house; the warm vapour from this will be very beneficial. If the vine border is at all dry, give it a good soaking with tepid water. See that all bearing rods are neatly trained; if any pruning neglected, attend to it at once. Vines bleeding through being pruned too late may be stopped by cutting raw potatoes to fit tight over the wound. Many are now starting their vines, and are committing the usual error of using too much heat. A temperature of 50° Fah. is the highest allowable for vines beginning to grow. As soon as they have expanded their first leaves a little, there may be an increase of 5° to 10°. It is important to tie in regularly, to stop laterals, and thin bunches, as these several tasks become due. Never allow more than one bunch on a spur; never more than a dozen on a strong rod. The temperature of vines on which the fruit is formed to be 55° to 60° night, 65° to 70° day. Bunches to be thinned as soon as the berries are of sufficient size. Tie in the young shoots and remove laterals early, so as to accomplish the pruning as much as possible with the finger and thumb. Be particular to lower the temperature at night. Very many of the failures in grape-growing arise through a too high night temperature. Those swelling fruit will require plenty of moisture. The cause of cracking is, in the majority of

cases, insufficient drink; and shanking arises through sour borders, where the drainage is imperfect.

STRAWBERRIES.—When put in to force, the pots should stand on fresh dung, and the plants should be allowed to root into it. By the time the berries are swelling the roots will be revelling in this rich food, and the fruit will be fine. As much light and air should be allowed as possible, and if the cultivator has time it will be well to fertilize the blossoms artificially. When a certain number of fruit are set, so as to swell off nearly simultaneously, nip out the remaining bloom-buds, and be content with a moderate crop. It is very important to keep the plants well watered; a few days' neglect of this may cause them to cast all their fruit.

Greenhouse and Conservatory.

GREENHOUSE.—A general shifting of all plant that are now coming into growth will be necessary, but those near their time of blooming must not be disturbed. All established plants that have filled their pots with roots and are making way towards bloom must be well soaked, as at this season the balls are often hard through getting dry during cold weather. The degree of heat must depend on the nature of the stock; where there are mixed collections, a generous temperature may be maintained, with moderate ventilation on fine mornings, and a decided lowering of the temperature at night. Cinerarias, Cytisuses, Primulas, Cyclamens, and other plants in bloom, or coming into bloom, must have good places and enough water. Camellias ought now to be in perfection; those in bloom to be kept rather cool, but as soon as the bloom is over they must have warmth and a close moist air to induce a healthy growth. Fire-heat may be used more liberally now, as there is more light, and many early subjects are advancing into bloom. Put Cinerarias, Primulas, and other soft-wooded, early-blooming plants as near the glass as possible, and where they can be freely ventilated on fine days. Give plenty of water to everything that is growing freely. Hard-wooded plants that have been kept dry all winter will probably need to be plunged to the rim of the pot in a vessel of tepid water, to soften the ball of earth, and allow water to pass through freely. When this is not done in spring, it often happens that having once got dry the water never afterwards wets the roots properly, but runs away down the sides of the pots, and after languishing some time, the plants die altogether. Get all stove plants from cutting-pans and boxes potted off. Start old plants of bedders to get cuttings, and put in cuttings as soon as they can be taken, to have the bedders forward in time to plant out strong. With the rise of the thermometer there will be an increase of green-fly, and plants with soft leaves will be attacked first. Look to the under sides of the leaves of Cinerarias, Calceolarias, Pelargoniums, &c., and if any fly, put the plants together in a box and fumigate, or fill the house with smoke, and syringe next day. In private collections, fumigating ought never to be needful. A plant here and there may be affected, but from single plants the fly can be easily removed with a soft brush, or by dipping in weak tobacco-water. All hard-wooded plants coming into leaf to be freely syringed. Temperature 45° at night, 55° to 60° by day. Bottom-heat for cuttings, 60° to 70°.

CONSERVATORY.—Climbers require attention now to remove dead wood, rub away any pushing buds that are badly placed, and to train in young shoots where desirable. Most of our conservatory climbers require a liberal heat now to start them into growth, with a free use of the syringe to keep down red spider.

GREENHOUSE PLANTS IN FLOWER.—*Acacia grandis, floribunda, holosericea.*—The soil should be sandy loam and peat, in a rough state, with lumps of turf and small nodules of charcoal. They occasion no trouble, and will endure some amount of ill-treatment without harm. Their foliage is so beautiful that they are worth growing well, irrespective of their lively yellow flowers. They are best propagated from seed in a hotbed in March, the seed to be soaked a few hours before sowing it. *Azalea obtusa, triumphans, Perryana, amena, lateritia, tricolor, aurantiaca, Fortunei, squamata.*—Any it may be desired to propagate should be layered as they go out of bloom. The layers will require to be twisted and covered with moss, into which the first roots will run, and allow of the removal of the layers earlier than by any other mode. *Brachysema lanceolatum.*—A beautiful fabaceous greenhouse evergreen climber from Swan River. Flowers scarlet, abundantly produced. Soil peat and loam, winter temperature 50° to 60°, summer temperature 55° to 65°, easily propagated from half-ripe shoots in sand. *Cytisus filipes.*—This pretty white-flowered broom is a charming plant for forcing, but it will bloom at this season in an intermediate house, and would be in no way improved by stove treatment. All the Cytisus are useful plants, and some of the hardy kinds of moderate growth are well worth potting, to decorate the conservatory. The best of the greenhouse kinds are elegans, yellow; filipes, white; laniger, yellow; rigidus, yellow; nubigenus, yellow; and proliferous, yellow. Though not particular as to soil, potted plants should have a light mixture of turfy loam with a little peat. *Dielytra spectabilis* is one of the easiest plants to grow, and one of the most beautiful to group with other spring flowers, and with foliage plants and hyacinths in the conservatory. We usually see it drawn and weak through insufficient light and air, for like many other subjects that bear ill-treatment patiently, it is thrust into the dark or subjected to excessive heat, and otherwise most unjustly dealt with. It is much better as a pot plant for the greenhouse than for the borders, for except in warm sheltered gardens, the spring frosts do it much damage when coming into bloom. The best way to deal with it is to pot the roots in loam, leaf, and old dung, equal parts; as soon as the stems die down in autumn, place the pots in a pit, and keep them only moderately moist. In November begin to force gently, and continue to introduce a few to the end of January. In May harden them off and turn them out into a rich border, and take up again when the foliage is withering. *Pimelia decussata.*—These favourites of the greenhouse are natives of New Holland, and require the treatment usually given to New Holland plants. The soil should be sandy fibrous peat and fibrous loam, with a plentiful admixture of nodules of charcoal, and good drainage. *P. decussata* is entered in our list simply because we happened to have it in bloom on the 23rd of February, in a warm greenhouse. But *spectabilis* and *Hendersonii* are much better. *Pimelias* are of very little use in small collections, as their colours are neither rich nor striking. To make the best of them, young plants should be frequently stopped to make them bushy. *Correa cardinalis, Brachysema longifolia, acuminata, hybridum, undulatum, Epacris impressa, Erica blanda, vernalis, rubrocalix, and triumphans,* also in bloom now.

AZALEAS to be kept going for succession, and always to be forced as gently as possible. Those wanting a shift should have it before being taken in to force, as the warmth which brings out the bloom will also promote the formation of new roots in the fresh soil. Where a mellow, fibrous, hazily

loam of a silky texture is attainable, use one-half in preference to using all peat. It causes a shorter and better growth, enables the cultivator to make a larger plant in a given sized pot, and in case of neglect in watering, &c., the plants suffer less than when potted in peat only. But unless the loam is really silky, and will crumble to dust between the fingers without soiling them, use peat alone (with sand of course) rather than risk these hair-rooted plants in a soil unfit for them. Azaleas in the forcing pit will now bear a heat of 60° to 70°, and must have abundant moisture.

SPECIMEN PLANTS will mostly want pruning, repotting, cleaning, &c., previously to being started into growth. It would be well to look over the stock of such things at once, that valuable time may not be lost.

BEGONIAS should now be repotted, and have large shifts when required afterwards.

LUCULIA ORATISSIMA deserves all the praise bestowed upon it as one of the choicest of spring-flowering plants. It is almost hardy, and may be as easily grown as any greenhouse plant with which we are acquainted. When grown in a pot, it should have a soil consisting of equal parts peat, turfy loam, and leaf-mould, with a large admixture of sharp sand; and as soon as done blooming it should be shaken out and repotted. But to do justice to it, it should have a conservatory border consisting chiefly of mellow loam; it will then grow with vigour, and flower superbly during the autumn, winter, and spring months, filling the house with its delicious fragrance. It has been well named "gratissima," and it is gratissima wherever it is known. A good companion for it is *Rhynchospermum jasminoides*, which produces its fragrant flowers during the summer.

FUCHSIAS.—Start the plants into growth, and when well broken repot. Cuttings struck now will make good plants this season. Fuchsias for beds may be propagated to any extent from a few old plants, and a very moderate temperature will set them growing for the purpose. Take off the young shoots when about three inches long, with a heel each.

PELARGONIUMS ought now to be growing freely, and on warm bright days should be watered so as to soak the ball and bring every rootlet into action. Use heat enough to allow of air being on all day. In bright weather sprinkle the floor of the house to create a humid atmosphere.

CINERARIAS will now want regular attention to preserve a healthy foliage as well as secure a good bloom. Drought will do them much harm, but they must have plenty of air, after being watered, to get their leaves dry before night. Green-fly will now infest them unless kept in check. Put the forwardest in the house for blooming.

CAMELLIAS are now coming into bloom, and need occasional doses of weak liquid manure, and frequent syringing of the foliage. It would be well to go over the whole stock, and sponge every leaf with tepid water, which will give the plants a bright and beautiful appearance, and very much promote their health. A hundred may be sponged in the course of a morning, when the weather does not allow of outdoor work; the sponge will remove soot and dust more effectually than the syringe. Plants done blooming must be kept warm, and enjoy a moist air. Camellias in bloom keep at 45° by night, and 55° to 60° by day, and with plenty of water. Plants for late flowering keep only just safe from frost.

BORONIAS, CHOROZEMAS, and other New Holland plants, require attention now. See that the soil in the pots is capable of taking up the water given; if hardened so that the water runs away from the pot, plunge them for half an hour on a bright morning. Young plants should be shifted on—the soil to be turfy peat, with plenty of sand, and a layer of charcoal over the drainage. Do not allow them to flower, but remove the buds as fast as they show, and occasionally stop the young shoots to induce a bushy habit.

Stove and Orchid House.

STOVE.—The temperature may be increased now with advantage. Achimenes are pushing briskly; these and Gloxinias to be potted to succeed the first batch. Soil, equal parts turfy loam and fibrous peat, with sufficient sand to render the mass porous. These require full light while growing, though their flowers must be shaded. The whole of the plants will need a general revision at this time of year; those that have been blooming all winter require to be cut back, and encouraged to break, then to be shifted to larger pots, if needful, or have top dressings; where very large specimens are objectionable, the plants may be kept in bounds by the knife; and to obviate the use of larger pots, turn them out, remove some of the soil from the outside of the balls, and repot them with fresh compost in the same pots. *Justicias* are now going out of bloom, and may be propagated to any extent, to make fine specimens for next season. *Poinsettia pulcherrima* and *Euphorbia Jacquinæflora* and *splendens* should be grown in quantity, as they are invaluable for conservatory and drawing-room. Now is the time to repot and start a number of fine subjects, such as *Gloriosa superba*, *Crinum*, *Begonias*, *Gloxinias*, various orchids, &c. There may be an increase of heat as the weather improves, and with it also an increase of atmospheric moisture. Remove all flowering plants to cool places to prolong their beauty. Train in and prune climbers, and keep a sharp look-out for vermin, for there will now be a general wake-up in the insect world.

ORCHID HOUSE.—Orchids will in many cases require to be repotted, and after which they must have the warmest end of the house. Those that do not need a shift should have a little of the old surface material removed, and its place supplied with fresh; at the same time make fastenings safe, and repair blocks and baskets.

KALOSANTHES give no proof of a gardener's skill in cultivating, but they do prove him to be a man of judgment if he provides a few specimens to make a blaze of colour in the conservatory. They are so gorgeous in bloom, and so easy to grow, that young hands should do their best with them, and all amateurs who are much away from home should pay them proper respect. Start them now in a temperature of 45° at night, rising to 60° by day. Repot first in a compost consisting of equal parts tough turfy loam, turfy peat, leaf-mould, hotbed manure rotted to powder, broken pots, and sharp sand. In this mixture they will grow superbly. They must have plenty of light.

Forcing Pit.

FORCING-PIT to be kept fully employed by putting in successional batches of various subjects in time to succeed those taken out.

CUCUMBERS FOR RIDGES to be sown now, or within a week or so. Sow also for frame culture to succeed plants now bearing. We prefer sowing in 60-size pots, two seeds in a pot, the strongest plant in each to be kept, and the roots never to be damaged by shifting, so as to have them strong and short for turning out.

PINES.—At certain seasons of the year pines are in greater request than others. For those seasons the cultivator should speculate boldly, for nothing

tends more directly to establish a gardener's reputation than to be able to supply plenty of pines, grapes, and other choice fruits in the season when lawn parties, and pic-nics, and dinners are fashionable. It will be found upon reflection that growers of pines have their principal work to do now to ensure a crop of fruit when it will be most valued and most needed. The work now chiefly demanding attention is to shift succession plants into their fruiting pots, and this should be done at once. It is of the utmost importance that the soil for the purpose be nearly dry and in a mellow condition. Strong stimulants are very objectionable, hence the only manure should be the surface of an old cucumber bed. There is no soil so good for pines as the turfy yellow loam from Wanstead; but as everybody cannot obtain this, the next best is any silks-textured loam that can be had containing plenty of fibre, and add to it turf from a roadside, chopped small, and in a rough state. To crock the pots carefully is not only necessary for the escape of water, but for the admission of heat from the plunge bed. The plants must, be plunged as soon as potted, and the bottom-heat should be 70°.

Correspondence.

ROSE'S "FAVOURITE" CUCUMBER.—As many letters have come to hand since I noticed this variety of cucumber in the autumn of last year—some asking for seeds, and others to know where it could be purchased—I am compelled to make a special notice on the subject. To reply privately to all applicants is utterly impossible with the time at my disposal for writing, and I hope those who have made inquiries upon the subject, and to whom I have not otherwise replied, will accept this as equivalent to a private letter. In the first place, I have to say that the few seeds which I had have been distributed amongst the first applicants, therefore I have none left for those who applied later; and as for purchasing them, so far as I am aware, it is not in the market. In fact, the whole stock is in the hands of some half-dozen cultivators, and as it is a very bad seeder, it is likely so to remain until some individual sets to work and grows expressly for the seed. But my experience of its seeding qualities is such that I would not undertake to do so, for every good seed obtained would be well worth a shilling, as there would be but a few of them, and that price would not be likely to suit the public. It is most improbable that it will become for some time widely distributed, for even those who have grown it for several years find it necessary to keep up their stock by striking cuttings two or three times a year. It would have given me considerable pleasure had I been able to make it better known, as it is one of those good things that ought to be in the hands of every cultivator of cucumbers.

J. C. CLARKE.

Replies to Queries.

Select Peas.—W. II.—In a trial of peas conducted at Stoke Newington last year, and reported on in the GARDENER'S MAGAZINE during the months of August and September last, the following results were obtained in respect to a certain number of varieties: *Sutton's Kingleader* (alias *Carter's First Crop*) was the earliest of all, coming to perfection in 85 days; and the next earliest was *Dickson's First and Best*, 88 days, which was more fruitful than *Kingleader*. The best of the first early kinds to succeed either of these were *Sangster's No. 1*, which was gathered in 91 days from the date of sowing; *Eley's Essex Rival*, 90 days; and *Early Emperor*, 92 days. The old *Ringwood Early*, coming into use in 90 days, is first-rate, and highly prolific, and being very hardy will be one of the best for exposed districts, where *Advancer*, a newer kind, requiring only 90 days, is apt to be injured by frost when sown early. The following are a few of the very best peas in cultivation, with the number of days from sowing to gathering in this trial. Of course their periods vary with seasons and soils and dates of sowing; when sown late, all the kinds come into use in a fewer number of days than when sown early—as, for example, *Yorkshire Hero* requires about 100 days if sown in March, but only 70 days if sown in the middle of May; *Auvergne*, 94 days; *Champion of Paris*, 98 days; *Princess Royal*, 100 days; *Vetch's Perfection*, 108 days; *Fortyfold Marrow*, 108 days; *Mammoth Marrow*, 108 days; *Lord Raglan*, 108 days; *Maclean's Wonderful*, 112 days; *The Prince* (Stuart and Mein), 115 days; *Hurst's Princess Royal*, 116 days. Many others were found to be good, but these are selected as the very best. As a great many inferior kinds are in cultivation, and cost as much to grow as the best, the names of a few of the worst varieties may be useful to our readers: *Carpenter's Express*, 90 days; *Alliance*, 94 days; *Climax*, 95 days; *Blue Scimitar*, 108 days; *Burbridge's Eclipse*, 105 days; *Dickson's Early Favourite*, 95 days; *Fairbeard's Surprise*, 98 days; *Fairbeard's Nonpareil*, 95 days; *Harrison's Royal Blue*, 94 days; *Harrison's Glory*, 95 days; *Harrison's Perfection*, 95 days; *Maclean's Gem*, 93 days; *Prince of Wales*, 100 days; *Prussian Blue*, 98 days. Many who grow these will be startled to find that we pronounce them inferior, but we can assure them that they are so as compared with those placed in the list of the best.

Gloxinias and Achimenes.—Young Beginner.—The *Gloxinias*, *Achimenes*, and *Begonias* will do well in the tan bed in the pit, but it is too hot a place for *Liliums*.

Tree Ferns in Open air Ferneries.—R. W. B.—We do not believe we shall ever see tree ferns established as permanent occupants of open-air ferneries in any part of England or Scotland. We have no objection to the experiment being tried by you or any one. But as you ask for an opinion we give it, and to this effect: that except in some very few peculiarly favoured spots in the south-west of England, no tree fern planted in the open ground can be expected to live more than three years. We do occasionally have two or three mild winters in succession in this country, and such species as *Dicksonia squarrosa* might live through them, but the first severe visitation of frost would make an end of them for ever. It is possible that in some of the warmest parts of Ireland places might be found for tree ferns, with the probability that they would last a few years, but the first really sharp winter would kill them even there. You have been, we fear, too much influenced by a mischievous article which appeared recently in a contemporary. We cannot advocate any cause that we believe must end in disappointment, but if you are determined to go on, we do hope you will send us every year an account of the condition of the plants until their career is ended.

Selections of Fruits.—R. W. Piper.—As you have the "Garden Oracle," it will be a very easy matter to select fruits for your walls and borders. It is an important matter for a cultivator to know exactly what he wants, for

the fruits that suit one will not suit another, and *vice versa*. Mr. Huish's new varieties of pears were described in former issues of the "Oracle," therefore there was no occasion to bring them forward again this year; we cannot afford space in the "Oracle" for stale facts.

Potato Disease.—R. Simson.—If people will attempt to grow potatoes in soil that is quite unfit for them, they must expect disease. Your cold wet clay is not a potato soil. That a rich soil is not of necessity inimical to the healthy growth of potatoes is proved by the market gardens all round London, which are constantly and abundantly manured, but they produce potatoes of the finest quality. But the market gardeners know the value of sorts that ripen early, and usually get their crops off and the ground planted with collards or cabbage long before the usual season for the outbreak of the disease arrives. The principal matter of importance in reference to manuring is that it should not be rank or recently added to the soil. A thin coating of Epsom salts on the surface of the soil when the potatoes are just pushing through is about the most effectual stimulant that can be used, and in some districts very cheap.

Natural Soil.—Zeno.—We do not know what is the natural soil for any plant; we only know that some grow better in clay than in gravel, some better in gravel than clay, &c., &c. Such knowledge is the foundation of good practice, and for all ordinary purposes is as good as absolute knowledge, which we do not possess. Mr. Charles Darwin has pointed out that many plants met with in a wild state are really in artificial circumstances, for when they become located in soil that suits them, they get killed out by other plants that grow more vigorously; whereas when located on soils which barely afford them the means of life, they maintain their standing because less pressed upon by more vigorous forms of vegetation. We say that calcareous matters—humus, silica, &c.—are necessities of life to this or that plant, but we may always be prepared to find that plants can substitute one element for another under certain circumstances, as many plants ordinarily requiring potash are able to subsist in soils that do not contain a particle of that salt, provided that in place of potash they contain soda.

Hollyhocks.—J. H., Halifax.—In deep strong loams hollyhocks attain to finer proportions than in light soils, but they really are not particular, provided the soil has some substance, and is liberally manured. It is quite true that hollyhocks may be grown as annuals; indeed seed sown now could be grown on to flower well this year. The person who affirms that this is impossible is simply ignorant. Grafting hollyhocks is not much in favour, but we have seen many a fine show of flowers on grafted plants. To make a good job of the grafting, the roots to be grafted on should be cut so as to be quite fresh and plump when operated on, and as soon as the grafts are inserted and tied, they must be potted in thumbs and be plunged in a gentle moist heat. Old stools of hollyhocks are grand as garden ornaments, but they do not produce such fine flowers as yearling plants from autumn cuttings.

Potatoes.—W. II. Halliday.—*Wheeler's Milky White* is good for keeping, and does not readily sprout in spring. It is white, mealy, well flavoured, highly productive, and hitherto has quite escaped disease. One of the finest market potatoes that it is possible to plant is the *American Red*, a large angular even tuber, keeping very late; the flesh is as white as snow, and the flavour little inferior to one of the best of the kidneys. You can obtain it true by applying to Messrs. G. Gibbs and Co., 25, Down Street, Piccadilly. The following are first-rate: *Vitch's Ashleaf*, *Mona's Pride*, *King, Queen, Fluke, Flourball*. Half a dozen sorts ought to suffice for any private garden. If you wish to embark in varieties, and waste your time in growing a great many had potatoes, we shall be able to assist you shortly, as we are preparing a report on the collection grown at Stoke Newington.

Endive Seed.—R. Baxter.—Your best plan is to allow the strongest plants now on the ground to remain. Three or four plants of each of the sorts you care about will furnish you with abundance of seed. If you have not any good enough, sow in March, and thin them out in good time, and the seed will be produced in autumn. The first is the best course, as you can make sure of seed. Sometimes the weather breaks down before late seeds are ripe: this was the case last year, and very much of the seed now on sale has been imported.

DISEASES OF PLANTS.

If we now examine the first deviations from normal phenomena which are exhibited in the occurrence of internal diseases, as for instance in smut (*Uredo segetum*), in decay, as in the stems of cacti, juicy fruits, &c., or in the potato murrain, we find in every case that the nitrogenous lining of the cells first becomes discoloured, assumes a darker tint, a firmer consistence, a more evident granulation, and that it begins at the same time to percolate and saturate the cell-wall, so that it ceases to exhibit its pure reaction on the cellulose. These phenomena are so general that we may well suppose that all inward diseases of plants actually derive their origin from an abnormal condition of this coat, and inasmuch as the peculiar power of the chemical process in the cells is apparently concentrated there, its deprivation first calls into existence the symptoms of disease which are perceptible at a later period in the other portions of the cells. The comparative luxuriance of plants depends upon the inorganic matters presented to them in the soil. The proportional rarity of phosphates in most geological formations, and also in the soils which are wholly or principally formed from them, is well known; on the contrary, they are accumulated in soils principally formed of decomposed vegetable matter after being slowly collected by the plants. Animal excrements are very rich in these salts, and therefore manured fields, and especially gardens, contain a greater proportion than is normally present in plants, or can be consumed by them. But the influence which inorganic substances in the soil exercise on vegetation depends upon their being generally present. For since plants have not the power of choosing their own nutriment, and since the proportions in which soluble substances present themselves for absorption can be altered by endosmosis within very narrow limits, it is equally important that the substances which are requisite for plants should be contained in the soil in something like the proper proportions, since the plants are otherwise compelled to receive matters in greater quantities than is agreeable to their normal structure, and in consequence inevitable anomalies take place in their vital action. The sum of what has been said may be stated thus: The more phosphates are relatively increased in any soil in consequence of its mode of formation or cultivation, the more will the plants which it sustains have a tendency to deviate from their original type, to form sub-species and varieties, and finally to be attacked and destroyed by internal disease.—*Journal of Agriculture for Nova Scotia.*

The Gardener's Magazine.

SATURDAY, FEBRUARY 9, 1867.

THE EFFECTS OF THE RECENT SEVERE FROST may now be ascertained with a useful degree of accuracy by the simple process of an inspection of the contents of our gardens. It is sufficiently evident that the low temperature of January 3, 4, and 5 of the present year has proved extensively destructive; less so, perhaps, than the dreadful frosty Christmas Day 1860, but nevertheless sufficiently so to distinguish 1867 as a year of special disaster to horticulturists, and afford a new test of the relative hardness of the various plants that have been newly introduced to our gardens since the date of the last great frost. If we go back to 1838, and compare the effects of the severe weather of the early part of that year with the present, we shall quickly discern how different are our circumstances now to what they were then. Since 1838, every part of the world has been contributing useful and beautiful forms of vegetation to our gardens, and from the shores of the Pacific, and from China and Japan, innumerable additions have been made to the embellishments of our flower borders, shrubberies, and even kitchen and fruit gardens. The latest Japanese importations have now been severely tried for the first time, and we regret to be compelled to confess that many of them have succumbed to the frosty ordeal to which they have been exposed. It is not surprising that Japanese plants should suffer in this country when the thermometer descends to a point near zero of Fahrenheit's scale, for although the high lands of Japan are subjected to low temperatures, the summers are longer and brighter than ours, and the seasonal growths are more perfectly matured than in our gardens, and better prepared therefore to withstand the shock of a severe frost. On the other hand, Californian trees appear to be perfectly adapted for this climate. Look for example at the beautiful *Cupressus Lawsoniana* anywhere in the three kingdoms, and it will be found to be unhurt, though *Deodars* and even *Araucaria imbricata* are in many instances very much discoloured. The truth is that we are well situated as respects mean temperature for the vegetation of the north American continent, for the isothermal line of 50° which passes through London in the latitude of 52°, dips as low as the 40th parallel in North America; but the same line passes north of Japan, and the line which cuts the main island represents a mean of 60°, which is the temperature of Spain and the northern shores of the Mediterranean. For Japanese plants to have a fair chance of becoming acclimatized in Europe, therefore, the climate of Spain is required; hence we need not be surprised that many of them when planted out in English gardens suffer in the event of an unusually severe winter.

The severe frost of 1860-61 followed upon a cold and excessively wet summer, and was destructive far beyond what it would have been after a long hot summer. Trees and shrubs were so gorged with sap, and their young shoots in such an unnatural state, that when the frost attacked them they burst like water-pipes, and were in many instances destroyed entirely, root and branch. The frost of 1867 followed upon a short summer and a wet autumn, for the summer of 1866 ended with the month of July; with August came rain, cold, wheat mildew, and potato rot. Therefore on this occasion subjects comparatively tender in constitution were ill prepared to sustain the shock, and many that are ordinarily exceedingly hardy plants were greatly injured wing to their sappy condition.

The frost of 1860-61 was peculiarly partial in extent and intensity. It was terribly severe in Scotland, thermometers in several places registering 13° below zero of Fahrenheit, while in Ireland frost was scarcely known, and tender plants left out from the previous summer were in many instances flowering freely, when in Scotland Hollies, *Deodaras*, Wellingtonias, and *Araucarias* were killed to the ground. The frost of 1867 prevailed with great severity in every part of the United Kingdom. In the midland and home counties it was more severe than in the north; at Chiswick, 11° below zero (43° of frost) was registered; in Scotland, the lowest point attained appears to have been 4° (28° of frost), and in no case, so far as we can learn, did the thermometer go down to zero. As for Cornwall, Devon, and the usually most favoured parts of Wales, none of these "English Italies" escaped entirely; they were visited with sharp gales, heavy falls of snow,

and the thermometer registered in some instances 15° of frost. The low temperature of January 3 and 4 was no doubt the cause of all the mischief of which the evidences now stare us in the face; it came suddenly, succeeding close upon mild growing weather, and it cannot be doubted that if it had not been preceded by a copious fall of snow, its effects would have been far more deadly. The following are a few of the minima registered on the 3rd, 4th, and 5th of January, with the names of places and authorities:—

Chiswick	—11°	Horticultural Society.
Colnbrook, Bucks ..	—5°	A. Pettigrew, Ric Park.
Slough	—8°	Charles Turner, Royal Nursery.
Feltham, Middlesex ..	—6°	Correspondent of <i>Gardener's Chronicle</i> .
Cotswold Hills	—9°	C. Hollingworth, Cowley Manor.
Winchfield, Hants ..	—12°	J. Bell, Strathfieldsaye.
Bury St. Edmunds ..	—7°	P. Grieve, Culford.
Newbury	—5°	C. Ross, Welford Park.
Nottingham	11°	E. J. Lowe, Nottingham.
Hampshire	4°	Correspondent of <i>Times</i> .
Hornsey	—4°	Correspondent of <i>Gardener's Magazine</i> .
Stoke Newington ..	5°	Correspondent of <i>Gardener's Magazine</i> .
Bicton, Devonshire ..	2°	James Barnes, Bicton.
Southampton	4°	J. Downing, Colour-Sergeant R.E.
Sawbridgeworth, Herts	4°	Thomas Rivers, Sawbridgeworth
Cobham, Surrey	—3°	Correspondent of <i>Times</i> .
Plymouth	16°	T. Smith, Beacon-field.
Heckfield, Hants ..	—4°	Correspondent of <i>Gardener's Chronicle</i> .
Torquay	12°	S. Garland, Bishopstowe.
Glasgow	4°	James Anderson, Meadow Bank.
Clapton, Middlesex ..	2°	Stuart Low, Clapton.
Ringwood, Hants ..	5°	H. Chilman, Somerley Gardens.
Merriott, Somerset ..	7°	J. Scott, Merriott.
Chepstow, South Wales	12½°	S. M. O., Sedbury Park.
Rhuabon, North Wales	3°	P. M., The Gardens, Wynnstay.
Croydon	—5°	J. C. Mundell, Hooley House.
Kidderminster	—6°	W. Jackson, Blakedown Nursery.
Cambridge	8°	J. J. Chater, Gonville Nursery.

The highest of these registrations are those for Torquay (20° of frost); Chepstow (19½° of frost); Nottingham (21° of frost); and Plymouth (16° of frost). The lowest were Winchfield, Hants (44° of frost); Chiswick (43° of frost); and Slough (40° of frost). In all cases we take the records to be correct, knowing that it is impossible they should be so, for thermometers vary considerably in registering extremely low temperatures, and scarcely any two agree at points below zero. But a few degrees of Fahrenheit's scale are of no consequence for general purposes, and if we take the foregoing figures to be truthful, they will no doubt very fairly represent the degrees of frost experienced in the several localities named.

As to the injuries done to vegetation, we find that wherever the frost has been very severe, the Brassica tribe has suffered severely. Brussels sprouts, broccolis, cabbages, and even the hardy borecoles have in many instances been melted down into an offensive pulp, and there will be of necessity a great scarcity of cabbage plants for spring planting, and a dearth of vegetables in the market for at least three months to come. Variegated kale, which has been so much praised for winter decoration of the flower garden, has been in many places completely destroyed. Amongst Japanese shrubs there has been considerable havoc. Some beautiful plants of the golden-leaved *Euonymus* at Stoke Newington have been so far injured that the last year's shoots are nearly all killed, and the leaves that were in beautiful condition on Christmas Day last, now hang about them like dirty rags. Those most injured happen to be situated where there is constantly a sharp current of air, which it is well known is oftentimes more destructive than still air of many degrees lower temperature. In the same district, *Araucarias* have been nearly killed by cold currents, while others remain unhurt, though only a few yards distant from those most injured, the difference in favour of these being that they have the shelter of a building from the north. The specimen *Araucaria* operated upon to produce a duplication of shoots (*vide GARDENER'S MAGAZINE*, p. 367, 1865) is quite untouched, though many of the duplicate shoots started late in the season, and are now of that vivid green colour which tells that they are scarcely yet ripened. *Aucubas* on cold damp soils have lost much of their soft wood, but are not seriously hurt. *Deodaras* and Wellingtonias about London are brown as cocoa-nut fibre, but in very few instances are they seriously hurt. A collection of varieties of ivies, green and variegated, in pots plunged in a very draughty border at Stoke Newington, are unhurt, with the exception of the Himalaica variety of *H. helix*, which is sadly killed back and denuded of all

its leaves, and the common variegated form of the Irish ivy, the whitest leaves of which are shrivelled and brown, so that the beauty of the plants is gone for the season. But the pretty marginalis series, and the golden and silver varieties of *H. helix*, both in the climbing and arborescent forms, are untouched; and Messrs. Lucombe and Pinee's beautiful creamy leaved tree ivy is now as bright as a good specimen of Flower of the Day geranium. Standard roses have suffered everywhere, and no wonder, for they were growing when the frost caught them; but many that appear to be dead will no doubt break from living buds near the work, and in time replace the heads that have been killed back. It appears that as a rule hybrid perpetuals do not suffer much until the thermometer descends below 10°, but at that point danger commences. Much, however, depends upon their condition at the time, and a frost increasing slowly in severity would do much less harm than such a sudden onslaught as they have been recently subjected to. We have lately seen some potatoes thrown out of newly dug ground. They are as sound as if no frost had ever touched them, though they were only covered with six inches of earth, and were no doubt frozen through at some time during the twenty-three days that the frost continued.

ON THE CHEMISTRY OF PLANTS.—A remarkable communication was lately read to the Royal Dublin Society by Professor C. A. Cameron. He stated that many plants belonging to the Cruciferae, Liliaceae, and Algæ contain from 20 to 36 per cent. of soda and common salt. "These substances are, however, not invariably present in plants, and I have succeeded in developing the most (apparently) soda-loving plants in soils perfectly destitute of that alkali. If, then, soda be as useless to plants as it is unessential to their perfect development, the practice of applying this alkali, or its compounds, for the purpose of fertilizing the soil, is based upon an erroneous belief in its manurial properties." He then proceeds to state as the result of experiments, that plants cannot be perfectly matured unless potash is supplied to them, and that "all the attempts made to substitute soda for potash failed completely. Although there are some strong points of analogy between potash and soda, they do not appear to me to be so nearly related as some chemists believe them to be; indeed in many respects soda approaches more closely to magnesia than to potash." What follows is still more interesting. During the past few years several new metals have been discovered, the majority of them being the metallic bases of certain earths. Thus aluminium is the metallic base of alumina, and is obtained from the earths that yield alum. So caesium, rubidium, tellurium, and other metals, the existence of which had been dimly suspected by Davy, have been discovered and eliminated from the oxides, sulphates, and other combinations constituting earthy matters of which they are the ultimate bases, the first substantial hint of their existence having been obtained through experiments on spectral analysis. It will interest all who are in any way acquainted with the progress of chemical science to learn that caesia and rubidia, both which form by combination with acids compounds that are all but identical with the corresponding salts of potash, are capable of being substituted for potash in the structure of plants. Some plants of parsley were grown in a soil destitute of potash, but were watered with a solution of chloride of rubidium. These plants grew, but not vigorously, and in due time flowered and produced seeds. It happens that in parsley potash usually occurs in very large quantities, and the author concludes that in this experiment the salt of rubidium was a true substitute for it. In another experiment seeds of parsley were sown in a soil destitute of potash, and the plants were not supplied with rubidium. These plants died within six weeks after the time of their being sown. The paper concludes with some further notes on experiments and analyses, in the course of which it is stated that probably rubidium is a necessary constituent of the beet plant, and that caesia has been discovered in wheat, cauliflower, mustard, coffee, and cherries. The full text of this important paper was published in the *Irish Farmer's Gazette* of Jan. 26, 1867, and to it we beg to refer those of our readers who desire to obtain particulars beyond the brief summary we have here attempted.

A FACT FOR HYBRIDISERS.—We learn from the leading Irish journal on farming and gardening matters that Phineas Riall, Esq., of Old Conna Hill, has now in his garden about 300 seedlings produced from *Amaryllis aulica* hybridised by *Lilium lancifolium*!!!

HABROTHAMNUS FASCICULATUS is a favourite plant with the gardeners of New York, who plant it in considerable numbers in the open ground during summer, and consider it one of the most effective of the class now known as "sub-tropical plants." It has not, so far as we are aware, had anything like a fair trial in this country.

ROYAL BOTANIC SOCIETY.—At the usual meeting of this society on Saturday last, Mr. C. R. Turner in the chair, several very valuable presentations to the museum and for the gardens were reported. One of the most interesting of these was a specimen of the "Garana bread," from Brazil. It is manufactured from the seed of the *Paullinia sorbilis*, a species of soapwort, and resembles cocoa in appearance. Its active properties are the same as those of tea, coffee, cocoa, maté, &c. It is manufactured in small oblong or round cakes, and is largely used in Brazil for a variety of dietetic and medicinal purposes. The specimens were presented by Mr. S. W. Silver.

By recent advices from America we learn that on the 18th of last month the conservatory attached to President Johnson's residence at Washington was entirely destroyed by fire. Thus almost simultaneously with the destruction of the noble collection of plants at the Crystal Palace, a similar loss was inflicted, and by similar means, on our friends across the Atlantic. The President's collection was alike celebrated for the rarity of many of the specimens, and their great size and beauty.

WILLIAM THOMPSON, TAVERN STREET, IPSWICH. *Descriptive Catalogue of Flower Seeds.*—This differs from the ordinary type of trade lists in the arrangement, which is according to the natural system, and the original, valuable, and eminently conscientious notes on subjects recently introduced. Lovers of choice herbaceous plants will find this worth perusal.

ROSES AND ROSES.—No. II.

There are some doleful tales current of the ravages of the frost among standard roses. From some of the nurseries in the north I hear of whole quarters having been destroyed, and that where there were thousands at Christmas there are but dozens now. Down in these southern parts the havoc made is something considerable, especially among Teas and Noisettes. I have just learnt from O P Q that he has lost his best heads of Ophirie, Narciss, Madame Falcot, Devoniensis, Boule d'Or, Souvenir d'un Ami, and that a few perpetuals have died outright, though duplicate plants of those killed remain unhurt. I do not wonder at losses in such a frost as that of January 3-4, 1867; for the system of rose-growing which prevails does little to adapt the plant to our climate, and indeed is in great part inimical to the existence of the rose, except as a half-hardy plant. Is there a rosarian anywhere in these realms who can get on at all without perpetually buying plants to make good losses from one cause or other? I say there is not. The trade have hit upon methods that keep lovers of roses constantly dependent on them for plants—like doctors who only patch up instead of curing their patients, and who, therefore, are regular visitors so long as the patients have faith in them. We are not to blame the trade because people go mad after standards. It is the policy no less than the duty of the trade to shape their course according to the requirements of their customers. The real grievance is that at the nurseries own roots are tabooed: you cannot obtain them for love or money. If you ask for them, you are told flat that it is all nonsense, a whim, a myth, a blunder, &c., &c., &c. Consequently, there is seldom a rose sold but it is on foster roots, and when we have such a winter as that of 1867, the rose garden is cleared of its occupants, and the rosarian has to begin again, and happy is he if his means enable him to do so. As for the standards, they have their uses, and it is agreeable to see them peeping out from masses of rhododendrons and mixtures of shrubs; but a plantation consisting wholly of standards is about as ugly an affair as can be found in the flower garden. That is a question of taste purely, but not solely. If O P Q considers standard roses the noblest of all the forms of floral beauty, it is not for me to quarrel with him. Let him grow them to any extent he pleases. He may even have a lot of mops made, and stick paper rosettes amongst the wool, and set these up in the parterre and swear he admires them. All I shall say is "Every one to his taste." I know a man who considers that strabismus (squinting) adds much to the beauty of the female face, and you may remember that Joe Grimaldi pronounced soy to be a grand accompaniment to apple tart. But there is another point worth considering, and it is this, that in very severe weather unprotected standards are exposed to the full fury of the blast and the frost in the whole extent of their heads, and their heads alone are all that one need be anxious about preserving. I persuaded O P Q to pull out of the ground one of his standards that had perished. It happened to be a Geant des Batailles, a very hardy variety, of which he has about a dozen others that are wholly unhurt. This was not only dead to the lowest bud of the head, but the stem was dead also. Yet when he drew it out of the soft ground, *the roots were all as fresh as if frost had never occurred*, and there were several plump pink suckers pushing, so that if it had been left alone a season, the dead stem would have been surrounded with a little thicket of shoots from the root. I thereupon offered him this practical observation, that if the plant had been Geant des Batailles *all over*, that is root and branch—in other words, if it had been on its own roots, neither budded nor grafted on the something else—there would have been no loss, only damage. The old growth might have been cut down to the ground, but with the advance of the season the suckers would rise, and Geant des Batailles would renew itself; but in the case before us it must be renewed by purchase.

There are not many amateurs who really understand all the points that arise out of this consideration. It cannot be helped. Once a year at least I do my part to strip from the subject of rose-growing all mystery and moonshine, and I now make such remarks as appear to be called for in reviewing the effects of the recent frost. O P Q has taken to standards with a fondness which astonishes me, for I never knew him to fail in detecting the beauties or defects of a piece of sculpture or architecture, and he is a capital judge of harmonies of colour; yet withal he finds beauty in standard roses, and no wonder, for some of our own brethren in the flesh find beauty in Hottentot women, and there was once a king of England who was fond of green oysters. But O P Q has in store a greater trouble than the loss of a few standards. He embarked in dwarfs pretty largely last year, and of course obtained manettis. The trade will give you nothing else, and in the hands of thorough masters of the rose, perhaps there is not much else wanted. For the propagator, the manetti is as good as magic. He can propagate it to any extent with scarcely any trouble. He can bud it in the open ground or in the steaming propagating house, or he can graft on the roots by the fireside all the winter through, and plant as soon as grafted, with the certainty of losing only about a dozen per thousand. No

wonder the trade like manetti, for it rivals the Indian juggler who by the touch of the wand upon a potful of earth causes a plant to spring up, and flower and bear fruit, in a few seconds, before the astonished eyes of his patron. As a vehicle, the manetti stock is valuable far beyond all the praise that can be invented. But for all soils and climates, for all circumstances, and for big and little gardens, it is not adapted for universal planting. Now let us look at the manetti border which O P Q has doated on. A very large proportion of the roses, mostly new varieties of H. P.'s, are gone for ever, and yet my dear friend does not know it. If I had told him when I saw him last, it would have been too much; the loss of his standard Teas is as much as he can bear up to the moment when this is published. Some of the manetti roses that the frost killed were black, and O P Q can see for himself that they are gone; but a considerable number of them appear to be alive, and only a little damaged; for the fact is, manetti suckers sprang up in plenty last year, and the frost has not hurt them, though it has carefully picked out and killed the rose part of the mixed head. The case is an exact counterpart of the brier just described. If left alone, the brier would keep its ground, and if left alone these manettis would do the same. I tried to teach O P Q's man how to distinguish manetti suckers by their neat bluish-green leaves, and the general absence of red or purple tints on the new shoots, &c., but I might have saved myself the trouble, for he soon managed to cut out the best part of a nice head of Emotion, under the impression that he had hit upon the distinguishing marks.

If we ask how it is that the frost injured some varieties more than others, the reply appears to be simple enough. We may say offhand that the varieties that suffered most were the most tender. But when we find a few out of a batch of one particular kind killed, and all the rest of that kind unhurt, or nearly so, the explanation is not so simple a matter. It is very certain that the warm moist weather we usually have up to Christmas is a bad preparative for the sharp frosts that usually follow. In the case before us, the plants were all growing; some of them bore nice flowers on Christmas Day; they were all covered with sappy young shoots, and were just in the right condition to catch it when the frost came upon them suddenly and cut them to the quick. The manettis were in the most growthy state of any, and this is its great fault as a permanent stock for outdoor roses. It is too excitable for this climate; it is reluctant to rest. Such weather as that of December last causes it to send up a rush of sap into the rose that is grafted on it, and in the event of hard weather, the rose being above-ground is killed, and the stock being below-ground escapes unhurt. The philosophy of the matter is as simple as can be. If every rose in the garden consists of two parts, they are less safe than when they consist each of one part; and own roots survive the hardest winter, because at the very worst, if the head is killed down, the root usually escapes, and in due time will make another head as good or better than the first. O P Q was astonished to see in a nursery shoots one year old and six feet long on manetti stocks. They were pointed out to him as proof sufficient that manetti is the best of stocks, and that none but a madman would utter a word against them. I took him into my garden, and showed him shoots eight, nine, and ten feet high on own roots, and he then began to doubt if it was prudent to believe the evidence of his own eyesight, and I am afraid his doubt will be renewed when he makes a serious investigation of his manetti border, or if he should wait till June and see how many of them that are apparently unhurt produce flowers.

Nothing that is here said will damp his ardour for roses. It is understood between us, as friends who know each other well, that I am to say whatever I please in respect of his roses, and I told him plain I would consider him to be the type of thousands of amateurs who think they have but to buy and plant, and for the rest of their lives they may have an abundance of the finest of roses. He may do a better thing yet than simply plant the best pot roses he can get, and the better thing will be to plant them in a better way. He intends I know to buy in a lot of the new roses this spring, and I am only afraid he will be in too great haste to plant them. The sooner he makes his purchase the better, because it is well to have the plants in the place a long time before planting them. If they should come out of a warm house, and the "work" has scarcely yet united, a considerable number must perish unless they are hardened carefully before planting. People see in the calendar of garden work that roses may still be planted, so they purchase manettis all fresh and bright from warm pits or greenhouses, transfer them to the open ground at once, and the next frost kills them. But if the plants were housed near the glass, and taken care of as cool greenhouse or pit plants till the end of April, and then were placed on a dry border for a week before planting, there would not be a single death among thousands.

But I haven't done with this business yet. I keep hammering away about own roots, and it seems that many amateurs find the striking of an eye or cutting to be an insuperable difficulty.

They say, "We cannot do it, and it's nonsense to enlarge upon its merits." Well, there are things hard to explain, and it is a mystery to me how any man fond of gardening, and a little bit used to garden work, should find a difficulty in making own-root roses, for after all it is nearly as easy a matter as making own-root geraniums. But never mind about the mystery; I propose to O P Q to buy his manetti roses at once, and to house them, keep them light and cool, and if the pots are quite full of roots to give them a shift after he has had them three weeks. Finally, they are to be planted in a border thoroughly well prepared, so as to be really *light and rich*—plenty of good rotten manure in it, plenty of turfy loam or leaf-mould, as good almost as if the stuff were to be used for potting. The planting must be so deep that the junction of rose and stock will be two inches below the surface. When the planting is done, the ground should be carefully trod round and between the plants, and then touched over with the rake to obliterate the feet-marks. But this is not all. Throughout the summer every shoot is to be pegged down firm, with a tongue cut underneath the point where the peg is inserted, and these pegged-down shoots are not to be disturbed until they have begun to grow as plants, when they may be separated and planted elsewhere. It would be good practice to leave them untouched a whole year. If O P Q will do this, he may have an average of half a dozen of own-root plants for every one of the manetti roses he plants this spring, and this without any struggle to acquire skill to strike eyes or cuttings. S. H.

THE PREPARATION OF BEDDING PLANTS.

In the present day no subject in connection with the work of the garden requires more care than the preparation of the usual number of bedding plants. So varied are the subjects used, and so great their numbers, that immediately the new year begins the gardener's troubles may be said to have commenced, for from that time until the beginning of May he must be perpetually at work either in sowing, striking, or potting, so as to secure a sufficient number of plants for the filling of innumerable beds, to say nothing of extravagantly long borders. But I must not venture further on that delicate ground, or I shall be tempted to say something that does not altogether please the best supporters of the present bedding system. So I would rather confine my remarks just now strictly to the heading of this article, and leave to those whom it most concerns the question as to whether it is good or bad judgment to have all the best energies directed to the decoration of the flower garden, to the evident injury and neglect of many other important subjects in connection with the garden.

In the foremost rank as a bedding plant stands the geranium, and it is unquestionably well deserving the prominence it has attained. But it is a question for its many thousand cultivators to decide whether geraniums would not rise still higher in our estimation if they were more liberally treated—I do not mean after they are placed out in the ground, but through the various stages of preparation for that purpose. We have all read, and some no doubt have heard some men say, that they bed out geraniums by thousands. This I do not dispute, because I have seen places where they may be counted by the thousand, but then what were they? They were plants it is true; but such small, miserable, weak-looking subjects, that would require a favourable two months' summer growth before they could be actually called good plants, and unfortunately such is the case with very many at the proper season of bedding-out.

Now I ask all those who are interested in geraniums as bedding plants, if we should not get an earlier result if, instead of growing them in thousands, we were to have only hundreds instead, but still devoting the same time and space to the few as we did to the many? But it must be understood here that I am putting it thus plainly to those who grow all their bedding geraniums in 60-size pots, because that is a practice I have proved to be a positive loss. Therefore I grow all mine in 48-size, and the result has been that my employer has asked me the last two seasons past how it is I get my bedding geraniums so much better and earlier than they used to be, although the convenience is the same for storing them. Now this success has been achieved (if I may assume to so highly commend it) by simply growing half the number of plants that used to be grown, which has given me the chance to do those well; therefore I have not only got my plants earlier in flower, but one well-grown plant in a 48-size pot has filled the space that two turned out of 60's used to do, and with more satisfaction to those for whose pleasure they were grown. I am well satisfied that multiplicity of numbers in bedding plants is a great evil. We too often find the gardener in a strait as to where they are to be housed and cared for. I am therefore tempted to say, Do not use small pots any more than you are obliged to. Hundreds of verbenas, for instance, may look very nice when potted off singly and carefully labelled in 60-size pots (too often they are put into thumbs); but suppose 48's had been used, with three plants in a pot, they

would want less room, there would be two labels less to write, and, above all, instead of having three pots to water there would only be one. Then look at the number of times these small pots want watering as compared to those of a large size; and, besides, small pots full of roots are from the 1st of March until the time they are bedded out positively suffering half of the time for want of water, even where they get good attention, because the small handful of soil in them cannot retain enough moisture to withstand the drying influences of our ordinary spring weather more than two or three hours. The consequence is that, being unable to get food to make sufficient headway, they are exposed to all the enemies peculiar to plant life in the shape of thrips, green fly, and red spider, and when put out in the borders they require some time to regain that luxuriant state of health that is essential to their future welfare. It is well known we have only to starve any plant in a pot of that description, and it will very soon become infested with one or all of its worst enemies, that can only be effectually got rid of by restoring the plant again to its usual state of health by careful attention and liberal treatment. This is just the case of hundreds, nay thousands of geraniums. They are through the winter months crowded in either pots or boxes as thick as they can well be huddled together, with no room to breathe, and then in the spring they are cramped into the dimensions of a 60-size pot, and the small quantity of soil which they hold is not capable of affording them any fresh nourishment after the first month, because the roots have drawn from it all the nutriment it contained. So they are left to shift as best they can, until their roots are furnished with a fresh supply after they are put out in either beds or borders. This is not the case with well-rooted cuttings potted up at the end of October in 48-size pots. In these they will keep growing all the winter, and by the time the generality of growers are potting theirs off in the spring, these will be fine large plants, and when carefully hardened off may be transferred to some temporary covering out of doors early in April. None of my plants for the last two years have had any other covering but Russian mats after the first week in that month. Some, no doubt, will say, How are we to winter them? My answer is, If you have room for a thousand plants in 60-size pots from the middle of February onwards (the time most people begin to pot off), you have room to winter five hundred in pots a size larger, because thus early in the year it is impossible to make more room by turning other things out of doors that have had shelter so far through the winter. Moreover, spring-potted cuttings require a deal of nursing; the first few weeks they must receive some amount of artificial heat to start them into growth, and it will be necessary to grow them under glass much longer in the spring than the autumn plants require—that is, if you wish to get your stock up to be worthy the name of plants. And then, what are they, when put out in the borders, as compared to those of the size which I advocate? Why it will take them six weeks of favourable weather after they are planted out before they get the size that the autumn potted cuttings were on the 1st of May.

My stock for next season's display of such sorts as Stella, Cybister, Christine, and Madame Vaucher, are already vigorous and large—such as I should not be able to purchase next May under six or eight shillings per dozen. I need not stop here to ask whether these plants, or those of the small-size-pot section potted in spring, will produce the earliest display of flower, because the result will be plain to every reader. But I must stop just to say that at the time spring plants are occupying both valuable time and space, mine will be of less trouble, as out of doors they will go early in April, when they will require water much less, and altogether less attention, than those under glass—to say nothing of the valuable room their removal will give under glass. Nor must I forget the importance of this early removal out of doors in hardening them off, as they have ample time to get thoroughly hardened; and if planted out in these southern counties the second week in May, they will suffer nothing from five or six degrees of frost. Of course I am aware that in some large establishments in the country it is not strictly necessary to get up an early display of flower in the beds and borders, as the plants are not wanted to be in their best until the end of August, or even later. In such cases, the small-plant system may answer, as they will have plenty of time to make a good growth before they are wanted to flower; but there are hundreds of other places to which these remarks are applicable, where an early display is quite as essential as a late one is in others; and it is not too late now for your readers to adopt my plan with geraniums this year, although it cannot be attended with the same degree of success as if it had been done in the autumn. But even now, if those plants standing in the cutting pots or boxes were put into 48-size pots instead of 60's, and grown on liberally until the end of April, the plants would flower much earlier, and a considerably less quantity would be required.

Then as to the benefit that other bedding plants would derive by being put into larger pots, the same arguments above used will

apply with equal force to them. Look at the hundreds of lobelias required in many places; now three of these placed in a 48-size pot will turn out quite as large, and more healthy, than out of thumb pots, and instead of having three pots to water, there will be only one. The same may be said of verbenas two or three in a pot, unless they are required for lines in ribbon borders. Perhaps then such varieties as Purple King may turn out best out of single pots. But when verbenas and petunias are required for masses, they will answer the purpose equally well when two or three are grown in 48-size pots. The same may be said of calceolarias; in fact, they are such vigorous-rooted subjects, that when grown with two plants in a larger pot, they do not suffer from drought so much; consequently they turn out healthier plants, although perhaps not quite so symmetrical in shape as single-grown plants. But for the matter of shape, that is soon set to rights when they are transferred to the open ground, which they ought to be in these parts quite by the end of April. Then there is the variegated alyssum. These may be grown to advantage with three in a pot; so also may many other subjects which I have not space here to name; but these will soon suggest themselves to the minds of those who have any inclination to give the plan a fair trial.

J. C. CLARKE.

SPIRÆA JAPONICA.

As an admirer and cultivator of choice herbaceous plants, I wonder much that this exquisitely beautiful subject is about as scarce in English gardens as the palms and aralias that have only been introduced as it were yesterday. The reason, perhaps, for this scarcity is that it is not quite hardy. But what of that? It needs usually the shelter of a frame or cool greenhouse, and in the west of England does very well in the common border. Living some twenty miles west of London, I find that unless I make a frame or greenhouse plant of it, the flowering is most unsatisfactory, but with just a little kindness it is one of the loveliest of all the spring flowers. The way I treat it is as follows. The plants are potted in 48-size, in any ordinarily good soil. I believe it would grow well in pounded bricks or crumbs of clay, but I pot it in some of the good mixtures that are about, such as fuchsia or geranium compost, and house the plants in November. A frame or pit answers, or under the stage of a greenhouse till February. Then they begin to grow, the first leaves rising like fern fronds, and very soon acquiring a beauty which makes them almost the rivals of ferns. Watering is a matter of course, plenty of light a matter of necessity, and protection from frost a *sine qua non*. Gentle forcing agrees with the plant, but stove heat ruins it. I never expect mine to bloom till quite the end of April, for having a good succession of spring flowers I never want this plant earlier; in fact, I prefer to keep it back till hyacinths are pretty well past. But it may be forced easily enough, and 60° is as much as it can stand. When bloomed late, it may be used for any purpose within doors or without. It then presents a number of excellent spikes of snow-white flowers; they are scarcely showy, but their elegance is delightful, and the shiny leaves which form a groundwork for the flowers make the plant beautiful all over. When forced so as to bloom in March, it must not be put out of doors, for a few degrees of frost will destroy the beauty of the flowers without seriously injuring the plants. When the flowering is past, I plunge the plants in a bed of coal ashes or cocoa-nut fibre, and they have the usual treatment of plants so situated—that is, water when they want it, and nothing more. In October they are beginning to lose their leaves. I then turn them out, cut every one clean through with a sharp knife, and pot in fresh soil, and house them as before. Thus if I began with a dozen plants last October, I should make two dozen of them next October, but if I wanted to get up a stock for sale, I should in the autumn cut each plant into half a dozen pieces or more, and pot separately in small pots. If specimens are wanted, they must be grown on year after year, and it will expedite their acquirement of magnitude if they are shifted twice a year instead of once; say, in October and in May, immediately after they have done blooming.

E. K.

GRIMSDALE AND SONS, UXBRIDGE, MIDDLESEX.—A pretty little book for the pocket, most beautifully printed, and quite a model for many of the trade who are over-fond of printing. It is given to customers, but strangers are charged threepence—a reasonable arrangement, and a check to people who collect catalogues for waste paper.

B. S. WILLIAMS, VICTORIA NURSERY, UPPER HOLLOWAY, LONDON, N. *Descriptive Catalogue of Flower and Vegetable Seeds, 1867.*—A very substantial and well-printed book, containing, besides copious lists of seeds of all kinds, lists of gladioli, amaryllis, caladiums, achimenes, gloxinias, and new annuals, bedding plants, &c. In the list of pees we see Poynter's Early described as the earliest, and Sutton's Ringlender is omitted. This won't do; and we shall hope for better things in the next issue of this excellent catalogue.

J. ILLMAN, STROOD, KENT. *Retail List of Soft-wooded, Bedding, and other Plants.*—Various and comprehensive, and in respect of geraniums and fuchsias profuse.

EFFECT OF THE LATE FROST ON STANDARD ROSE TREES.

The following information may be interesting as well as useful to rosarians, and also serve as a guide to persons purchasing roses, particularly those who reside in the northern counties.

My residence is in the rich vale of Mowbray, Yorkshire, and is about twelve miles south of Darlington, which is in the county of Durham, a very cold part of England. In the winter of 1860 I lost all my fine collection of roses. Since that time the thermometer in my garden has never registered lower than 10° or 22° of frost, consequently I never lost many roses until the present winter. On the morning of the 1st of January last, my thermometer (a proved one, four feet from the ground) registered 5° below zero; again on the 4th it went down to zero. On other dates up to the 23rd, on which day a thaw set in, the frosty nights varied from 8 to 28° of frost, nearly down to zero again. After the storm had fairly subsided, I went into the garden to examine my favourites: there they stood in long lines, with the colour of their heads changed from a beautiful green to a sickly brown. Some appeared variegated, having here and there a green and brown shoot on their heads; others, again, maintained their original lively green, the frost not having had the least effect on them. It is to these that I wish to direct particular attention. I have examined about two thousand standard roses, and taken my notes very carefully. I propose to divide the result into three sections—hardy perpetual, half-hardy, and very tender, as follows:—

ROSES TWICE TRIED.

List of standard roses which proved themselves to be hardy, having withstood the severe frost of 5° below zero on the night of the 31st December, 1866, and other severe night frosts up to the 23rd January, 1867, without sustaining the slightest damage, the number grown of each variety varying from four to twenty: Madame Alfred de Rougemont, Madame Souppert, Louise Darzens, three French white roses, Charles Lefebvre, very hardy; Gloire de Dijon, Reynolds Hole, La Tour du Crouy, bad opener; General Brea, Gabriel de Peyronny, Louise Odier, a Bourbon, very hardy; Jean Goujon, Maurice Bernardin, Gloire de Santenay, shy bloomer; John Hopper, Charles Wood, Madame C. Wood, Madame Cambaceres, Jean Rosenkrantz, Jules Margottin, Baronne Prevost, Madame Derreux Douville, Duc de Bassano, King's Acre, Alpaide de Rotalier, Pavillon de Pregny, Catherine Guillot, another Bourbon, is very hardy; Madame William Paul is very hardy, and William Paul is very tender. Fourteen dead: Ami Vibert, Dr. Marx, a good old rose; Salet and Madame E. Ory, perpetual moss roses; Madame Furtado, Rev. H. Dombrain and Reviel, hardy Bourbons; Centifolia Rosea, General Washington, Gloire de Bordeaux, a Tea, quite hardy as a standard; Madame Hector Jacquin, Alphonse de Lamartine, Madame Boll, Vicomte de Cussey, a Bourbon; Duchesse de Caylus, Madame Laffay, Duchesse de Morny, extra hardy; Sir Joseph Paxton, H. Laurentius, and about twenty varieties of old summer roses—Paul Ricaut, Coup d'Hebe, &c., &c.

NEARLY HARDY PERPETUALS.

List of perpetual roses which proved to be about half-hardy, some of the branches appearing green and lively, and others brown and quite dead. Most of these I expect to survive as spring approaches; the number of each grown varying as before stated:—Pierre Notting; Madame C. Joigneaux; Princesse Olympie; Empress Eugenie; Vicomtesse Douglass; Dr. Spitzer; Victor Verdier; Vanqueur de Goliath; Madame Freeman; Duc de Cazes, almost hardy; Duc de Rohan; Sir Rowland Hill; Madame Vidot; Madame Louise Carique; Alexandre Bachmetoff; Celine Touvais; Souvenir de Marechal Serrurier; Dr. Andry; Vicomte Vigier; Jean Touvais; L'Elegante, Nouvelle; Alexander Fontaine; Madame Emain; Madame Domage; Adolphe Nohlet; Andre Leroy; Madame Knorr; Mathurin Regnier, somewhat harder than William Griffiths; Souvenir delà Reine d'Angleterre; La Esmeralda; Madame Victor Verdier; Richard Smith, worthless; La Brillante, nearly hardy; Alphonse Belin; Comtesse de Paris; Souvenir de Comte Cavour; La Ville de St. Denis; Lord Raglan; La Coquette; Baron Adolphe de Rothschild; Le Baron de Rothschild; Marie Thierry; Duchesse Medina Cœli; Beauty of Waltham; Professor Koch; Colonel de Rougemont; Madame Julie Daran; General d'Hautpault; Paul de la Meillerez; Madame Victor Verdier; Marechal Vaillant; Olivier Delhomme; Madame Charles Crapelet.

TENDER PERPETUALS.

List of perpetual standard roses that are very tender, the whole of which were killed, not a vestige of life appearing about them; number of each variety, varying as before stated, from four to twenty:—Dr. Berthet, Comtesse Barbantanne, Baron de Noirmont, Souvenir de Malmaison, Henri Lecoq, all Bourbons; William Pfitzer, General Jacqueminot, Marechal Forey, Madame Guinousseau, William Griffiths, Bernard Palissy, Auguste Mie, Pauline Lantzeur, Jean Bart, Madame Boutin, Empereur de Maroc, Princess Alice, George Prince, Admiral Nelson, Bernardin St. Pierre, Souvenir de Leveson Gower, Belle de Bourg la Reine, William Paul (very tender), Lord Macaulay, Lord Clyde, Lord Palmerston, Madame Brianson, Comtesse Chabillant, Prince Camille de Rohan, Belle Rose, Turenne, Alphonse Damaizin, Souvenir de William Wood, Sœur des Anges, Gloire de Chatillon, Madame Philip, Le Rbone, Senateur Vaisse, Charles Margottin, President Lincoln, Notre Dame de Fourvieres, Souvenir de Charles Montault, Comtesse de Segnier, General Forey, Francois Lacharme, Acidalie (Bourbon), Celine Touvais, La Quintinie and George Peesbody (both Bourbons), Madame Rivers, Sombrhieu (Tea), Le Mont d'Or, Gloire de Vitry, Louis XIV., Anna Alexieff, Anna de Diesbach, Lelia or Louise Peyronny, Comte de Nantieu, Triomphe des Anges, Madame Place, Monsieur de Montigny, Triomphe de Lyon, Souvenir de Lady Eardley, John Nasmyth, Cardinal Patrizzi, Alexandrina de Belfroy, Geant des Batailles, Prince Imperial, Appoline and Pierre de St. Cyr (both Bourbons), Madame Pauline Villot, Robert Fortune, Baron Hallez, Alexander Dumas, Triomphe d'Amiens, Thomas Rivers (Bourbon), Caroline de Sansalles, and Peter Lawson.

TENDER TEAS AND NOISETTES.

The following tea-scented were all killed:—Jean Hardy, Jaune d'Or, Madame Willermoz, Madame Falcot, Souvenir d'un Ami, Sombriuel (Noisettes, killed, some on walls), Adele Pavie, Ophirie, Polonie Bourdin, Solfaterre, Triomphe de Rennes, Narcisse, Fellenberg, Camellia Rouge, Aristide, Madame Massot, and Celine Forestier.

NEW HARDY PERPETUALS.

I budded about two hundred brier stocks with the new roses of 1866. The following made wood from 9 to 18 inches in length, and survived without any protection:—Camille Bernardin, eight plants; Jules César, four plants; Fisher Holmes, seven plants; Alfred Colomh, five plants; Prudence Besson, large petals, thin, four plants; Exposition de Brie, three plants; Souvenir de Dr. Jamin, four plants. Margaret Dombrain and Jean Lambert I have proved to be tender; not one survived.

MANETTI ROSES.

Roses on the manetti stock appear to be more tender than on the brier; all mine, with the exception of about half a dozen, were cut down to the snow mark. There is this great advantage in growing manetti roses—they are sure to spring up again from below the soil.* I find John Hopper, Charles Lefebvre, Madame Cambaceres, Contifolia rosea, Madame William Paul, Alpaide de Rotalier, Jean Rosenkrantz, and Madame Souppert, the only roses that were not cut down out of about two hundred grown on manetti.

I do not think that any of the perpetual roses are safe under a zeroic frost; experience has proved to me that any of the roses before named are safe under 20 to 22 degrees of frost (I mean a thermometer down to 10 degrees), but beyond that there is great danger.

I hope and trust that many rosarians will forward to the Editor of the GARDENER'S MAGAZINE a statement similar to this, as it is only by statistical information derived from various parts of England as to the habits of roses that we can ever hope to become clever rosarians. H. TAYLOR.
Rose Cottage, Fencote, near Ecdale, Yorkshire, 4th February, 1867.

CATALOGUES.

E. G. HENDERSON AND SON, WELLINGTON ROAD, ST. JOHN'S WOOD. *Catalogue of Flower, Vegetable, and Agricultural Seeds.*—One of the most copious of seed lists, yet free from the faults of "fat catalogues," for it attempts no more than to place before the cultivator names and descriptions of the best species and varieties in the several classes. Amongst the few novelties enumerated at the end, we see with much pleasure *Poa trivialis argentea elegans* the new and very beautiful variegated grass, offered at 2s. 6d. per plant.

SMITH AND SIMONS, BUCHANAN STREET, GLASGOW. *Cultural Guide and Descriptive Catalogue.*—Full of useful information, and arranged so as to indicate at once which are the best varieties in the several sections. In the paragraph on onion culture it is recommended to sow a few carrots in a bed of onions, and a few onions in a bed of carrots, in gardens where either of these useful roots are usually destroyed by grub. This doubtless is on the same principle that we plant lettuces in plantations of dahlias and hollyhocks, to give the insect pests a choice of dainties.

BARR AND SUGDEN, KING STREET, COVENT GARDEN, LONDON, W.C. *Descriptive Priced List of Seeds for Flower and Kitchen Gard.*—An excellent list, containing, besides the usual good selections, many interesting items, such as Anchu Japonica seeds at 1s. each, numerous "sub-tropicals," a new race of chrysanthemums, collections of carnation and picotee seeds grown by Mr. Stuart of Nice, and very large assortments of gourds and grasses. This would be more agreeable if printed on white paper.

JOHN FRASER, LEA BRIDGE ROAD, ESSEX, N.E. *General Descriptive Seed Catalogue.*—A very neat and complete catalogue, containing an admirable selection of fine-foliaged plants suitable to grow from seed, with lists of strawberries, gladioli, and hardy annuals, perennials, &c.

A. BREWIN, 6, COLEMAN STREET, E.C. *Catalogue of Garden, Flower, and Agricultural Seeds.*—A thoroughly good business-like list, adapted for filling in for orders, and containing everything that is in demand now.

THE GARDEN ORACLE AND FLORICULTURAL YEAR-BOOK AND ALMANAC FOR 1867. Groombridge and Sons, 5, Paternoster Row, London. Edited by SHIRLEY HIBBERD, Esq., F.R.H.S. Price One Shilling.—Have any of our readers made the acquaintance of, or consulted in their difficulties, the GARDEN ORACLE? If not, by all means let them place themselves in communication with, and act confidently on the practical and reliable whisperings of this little horticultural sybil. Unique in design and arrangement, and brimful of useful and every-day required information, it is one of the most perfect horticultural manuals the amateur could take up, or the practical man have at his elbow. A glance at the contents will afford some idea of the value to be had for the small outlay of a shilling. Extending over eleven closely printed pages, we have first an immense amount of tabulated information, both interesting and useful, much of it specially so to gardeners, *e. g.*, carefully prepared tables, showing the number of trees or plants required for any given quantity of ground, for calculating the cost of draining, the quantity of guano requisite per yard, perch, or acre. Tables for calculating the quantity of four-inch pipes required for heating, forcing, or plant houses. Tables of the day and night temperatures of the pine pit, vinery, and orchid-house, with allowances for the rise by sunshine during each month of the year. The vinery temperatures are of especial interest to the amateur, as he is shown at a glance what with which to start his vines, what when the blossom shows, what when in flower, and what when the fruit is set. The distinction is shown as to what is required for cool growing kinds, as the Black Hamburgh, and those that require a higher temperature to perfect their fruit, as the Muscat of Alexandria, &c. The calendar follows, and a most unique and thoroughly horticultural calendar it is, giving, besides all the usual calendrical information, a carefully selected list of as many choice varieties as there are days in the month of some speciality, with marginal cultural notes that will be found very valuable. Opposite the calendar for each month there is a closely-ruled blank page for manuscript memoranda. Then follows an elaborate calendar of work to be done each month in every department of the garden. Then we have, extended over some forty pages, descriptive lists of the new plants, new florists' plants and flowers, new fruits, and new vegetables of the past year. These lists will be found useful, and what is more, trustworthy. The editor does not flatter nor praise indiscriminately. These lists are supplemented by what will be found specially useful, *viz.*, selections of the *cream* of the varieties of the most popular plants and flowers. The concluding pages are devoted to notes on new fruits, and a chapter of "Olds and Ends," in the last are several tit-bits.—*Irish Farmer's Gazette*, Feb. 2, 1867.—[Advt.]

* This remark needs qualifying. Too often the manetti suckers rise, but the rose that was originally grafted on it is seen no more.—Ed.

LILIUM AURATUM.

By this time the golden-rayed lily, the queen of this wondrous race, is known in every garden where plants of value and beauty are regarded with admiration. The excitement resultant from its first presentation to public notice in England was no greater than occurred on the Continent, for indeed in every great city of Europe *Lilium auratum* has had an ovation. Having had a great part in successfully adapting this lily to the exigencies of cultivation and the multiplication of the bulbs for sale, I will give a short account of what I know on the subject. In common with all other soft-skinned bulbs, this lily is much injured by being a long time removed from the soil; indeed, it should never be exposed to the atmosphere, and when in the merchant's hands should be preserved in sand or buckwheat chaff, or, better still, damp cocoa-nut fibre. This time of the year is certainly the best to buy bulbs for planting, for they are now at rest, except where they have been forced early in the previous year, in which case they may be now growing freely, which reminds me to say that as this lily is quite hardy, and yet will bear a considerable degree of heat, *it may be so grown as to be in bloom at any season of the year*. There is not a month in all the twelve that I have not had for my delight the gold striped flowers of this gorgeous beauty. But the summer is the proper time for it to bloom, and by growing it naturally less skill is required than to change its seasons. I suppose, then, the amateur may purchase of the merchant bulbs that have just reached him from Japan. These will be drier than

parts fibrous peat, and four parts fibrous mellow loam, such as will break short in the hand without soiling the fingers. When good, this loam is of a yellow, or dunkelbraun (auburn), and contains oftentimes the fleshy roots of the European *Pteris*. Add to this two parts of silver-sand which is free from brown spots, for these spots predicate the presence of iron, which seems not to agree with any soft-skinned bulbs. Lastly, add one part of manure quite rotted to powder. This is the best of all mixtures—far better than peat alone, though in peat with silver-sand they grow and flower well. I hope those who follow my directions at all will follow them precisely, as I will not say that manure only partly decayed, or in great quantity, will be good for the plant. But what I do direct I have proved beyond all doubt.

There is one more point which I had almost forgotten. Newly-imported bulbs must *NOT be potted firm*. When the bulb is in its place, and surrounded with soil, strike the pot on the table to settle the soil, but do not press it in with the thumbs as you would in finishing a hard-wooded plant, for those half-shrivalled bulbs swell very much before they begin to grow, and room must be allowed for that. A very fine bulb I had once that was potted quite firm, burst the pot on the tenth day after it was placed on the bark bed, and I found it then to be nearly twice the size it was when it came to my hands.

I would urgently advise the cultivator not to use larger pots than the roots may be expected to *fill* during the season of their

LILIUM AURATUM.

Mr. Dodd's specimen, with 43 flowers, from a photograph.

desirable, and if they are potted as for growth, and at once watered, they will rot and be lost. The safe method of procedure is to clean the bulbs with care in order to remove all damaged portions. Then proceed to pot them in *small pots*—such that will barely suffice to allow them room for growth. The largest imported bulbs will require only 5-inch pots, and the smallest 3-inch. Put over the hole in the pot one hollow potsherd, and on that a few fragments of charcoal, and nearly fill the pot with a mixture of equal parts of peat and silver-sand. In this place the bulb, with the crown even with the edge of the pot, and fill up over the crown, so as to form a miniature mound, some of the same mixture of peat and sand, or some of the finest of the cocoa-nut fibre. The soil should be quite moist, but not wet, and there must be no water given for some time—not indeed until they have begun to grow. I have always sought for my newly imported bulbs when potted a cool bark bed at about 60°, in which I have plunged the pots to the rim. But any place will do for them that is warm and rather close; they do not want light or air for a long time, and it is desirable to prevent evaporation in order to preserve sufficient moisture in the pots without having to give water. Every cultivator can best design for himself a suitable place, knowing what are the needful conditions.

To grow specimen bulbs that have been in the country a year, and have been properly rested after flowering, is a most easy matter. The best of all soil for them, as I have proved by growing them in groups, each group differently treated, is that which consists of four

growth. This is most important. Indeed, I would prefer the pot too small rather than too large, if compelled to choose between the two evils; but I would escape all evils if possible, and find for every bulb, according to its size, sufficient pot-room, and no more. But here we find a good quality of this glorious lily (it has not a bad quality that I could ever discover); it is that we may make amends for contracted pot-room by means of liquid manure. Do not give this until *the pots are full of roots, and the flower-buds are visible*. Up to this time water should be supplied regularly and plentifully, but not in that dash-splash way that washes the goodness from the soil, and which is the too general way of watering everywhere. The careful waterer will place his finger on the spout of the pot, and regulate the flow to flood the surface of the soil just enough to go quite through, and not to spare. I think you English have too much water, and you do harm by wasting it. I could show you some places where there is not quite so much, and yet the plants have not yet died of thirst. For the liquid manure, any of the ordinary ingredients may be used, and if from the stable or sheep-pen, I should prefer the liquid to be quite clear, and the colour of the palest ale. When the flowers begin to expand, no more liquid manure should be given.

To grow this lily well a cool house is to be preferred. But they will always commence growth nicely by being placed in a moist heat of 55° to 60°. When they have grown six inches, they may be put into a heat of 70°, but must have full light, with a little shade from the hottest sun. By such treatment there

will be an early bloom. When not forced, the greenhouse or pit will answer; and indeed this liliun may be grown in the same way as the beautiful *L. speciosum* or *lancifolium*, and will never disappoint the cultivator; but I have always seen the finest flowers where a moist and gentle heat and liquid manure were employed, and I am thus prolix about small particulars because of the ambition of many to exhibit the plant in the best condition. When the flowering is over, take those that have been forced to a greenhouse, and those that have flowered in a greenhouse to a pit, and tend them with care, giving less and less water till the leaves decay. *They must not be dried off*, but be rested in a moist state; indeed it would spoil the next flowers of the finest bulbs to allow them to go dry during winter. To be wet is of course injurious; but to be sheltered, dark, uniformly moist by standing the pots on a bed of soil, and in a temperature of about 40° all the winter, is to be in the most perfect conditions for future well doing. I have found by attentive observation that the roots of this lily are always slightly in action, and to dry them off is to do them much harm. As to repotting for the next season, it may be done any time during the winter, or indeed directly after the leaves have died down, or it may be deferred till the new growth appears above the old soil, but no further delay is allowable. If I had always my choice, I would repot as soon as the leaves were quite dead, for then there is the least danger of injury to the roots.

I shall now speak of the propagation of this liliun, for it will be in great demand for many years to come. There are two ways—by seed and by scales. The first is the most interesting, because of the various characters of the flowers of seedling plants; the second is a certain and profitable method of perpetuating any particular variety. As to growing the seed, I would advise the amateur to cross the varieties of liliuns in every way that may be possible, for pollen is produced in extravagant plenty, and the operation is most easily performed. A register should be kept of every cross effected, so that when some grand novelty is produced we may be able to rely upon the raiser for the account of its origin. It is best to keep the seed till January, and then to sow it in boxes or large pans in four inches depth of such a mixture as advised for established bulbs. Sow them very thinly, and cover with one inch of soil, and place the pans where there is a continuous temperature of 50° to 60°, neither higher nor lower. Keep them always moderately moist, but never give a drop too much water. Some will spear through in three weeks; some will not stir for three months; and some will have minute bulbs within the soil in antecedence of the leaves. For these various reasons the seed-pans should not be disturbed for one whole year. But from time to time forward plants may be lifted out by means of a piece of stick, and be planted in other pans to grow with better advantages. I would not pot one till the bulbs were as large as hazel-nuts.

To multiply by scales is easy enough. Detach the scales without bruising them, and put them in pans filled with a mixture of equal parts peat and sand, pretty close together, the base of each scale within the soil, and the point of each scale just peeping out. The best place for pans so filled is in a moist atmosphere, with a temperature from 50° to 60°, until little green leaves appear; then put them in a heat of 70°. Previous to leaves appearing, they must have scarcely any water, but *must never be quite dry*. When they have made one full season's growth, they may be separately potted, but I far prefer boxes until they are approaching flowering size, as better for them and less trouble to the cultivator. In all these operations, the chief requisites for success are WATCHFULNESS and PATIENCE. As to skill, there is none wanted beyond such as every practical man possesses already.

The Editor has obligingly furnished me with some particulars of specimens that have been exhibited in England, and also with a stereoscopic picture of the best plant hitherto known. With his permission, I will not avail myself of all the particulars sent, as the practical rather than the historical has influenced me in drawing up the foregoing as the epitome of practice. When first flowered in England, it produced only one flower at the summit of the stem, and Dr. Hooker therefore named it *Lilium uniflora*! Very soon it was found capable of producing seven flowers on one stem, and the name was changed to one descriptive of its characteristic beauty. On the 8th of August, 1865, Mr. Constatine exhibited at Kensington a plant which from one bulb produced two stems, one bearing fifteen and the other fourteen flowers, being twenty-nine in all. I find in the GARDENER'S MAGAZINE of Sept. 29, 1866, an account of a specimen grown by Mr. Bullen, gardener at Bow Bridge, Leicester (known too as one of the best of cultivators of orchids) that produced three stems from one bulb. The two largest of these stems were 9 feet 6 inches high and 3¼ inches girth near the bottom. These two stems bore between them twenty-seven flowers; the third stem was very small, with only one flower, making twenty-eight in all. This plant was put in the East India orchid house from the time the buds were half matured till they were quite expanded, and Mr. Bullen

says, "when taken in this stage, its forcing qualities are excellent." But better still than these was the specimen flowered in June last by Mr. Dodds, the able gardener at Ashton Court, near Bristol, for this plant produced in all forty-three flowers, a truly wondrous spectacle, and which I will fain believe none of us shall see surpassed! I am favoured with an exact reproduction of the photograph of this plant for the embellishment of this paper. It might have been worked into a grand picture, but it was thought best to reproduce as nearly as possible the natural shadow of the plant and its surroundings, and I hope the reader will approve of this step as preferable to mere effect at the expense of sober truth. I have nothing more to say, except that this liliun is hardy, and will grow beautifully in a sheltered rhododendron bed. At the end of March would be soon enough to plant the bulbs; they should be put 4 inches deep, with a handful of sand at the bottom of the hole, and the hole filled up with sand above them. I advise to lift them carefully when the leaves wither, and pack them away in damp cocoa-nut fibre in a place safe from frost, but where they will not get quite dry, all the winter, and again plant them in March. When the bulbs are cheaper than at present, they may be left in the ground all the winter, but as hard frost after heavy rain might kill them, taking up is the best plan while the bulbs are too dear to be exposed to risks.

KARL PROSPER.

POTATO DISEASE.

I am a thorough convert to the doctrines enunciated in the GARDENER'S MAGAZINE on the subject of potato disease. I have been a cultivator and a close observer of the potato for more than a quarter of a century, and I believe with our Editor that the cause of the disease is a check given by cold when the tubers are ripening. The theory is as valuable as it is true. All my early kinds were truly grand last season, but my late sorts are gone. The cold that set in with August swept them away. I regret very much that during the winter we have had no Webb's Imperials on the table, for that was my favourite potato—so snow-white, so well flavoured, so mealy, so handsome. But it was never a profitable potato with me. Milky White deserves all that has been said of it, for the disease did not touch it, though it was far from ripe when the weather changed in August last. Red Ashleaf was good, though I do not care much about it for the table; it is not first-class. As planting time is approaching, I advise my brother amateurs to plant plenty of the early sorts and few of the late sorts, for potatoes are never safe in this country after July.

R. E. P.

THE EUCOMIS JAPONICUS.

Will it be out of place to inquire here why this plant is so little known, and still less cultivated? It certainly is not because it requires expensive appliances to grow it, that it is difficult to manage, or in any way wanting in grace and beauty to repay the cultivator for the labour and care expended. Even were it multiplied fiftyfold, I cannot account for its neglect in any other way than that the numberless new things which are continually appearing so captivate the attention, and occupy so much more room, that older and far better plants have to go to the wall. There are hundreds, if not thousands of plants at the present day occupying posts of honour in our houses and gardens which bear no comparison to this and many other old plants that I could mention. I do not despise everything new; and when a plant really is an acquisition, instead of being merely an addition to our already extensive lists, I can appreciate it as much and enjoy it as thoroughly as most people; but I do regret that the run after novelties should so effectually shut out many deserving old friends, whose only faults and disqualifications are the length of time they have been known in the country, and their complete destitution of novelty. Most varieties of the *Eucomis* were introduced from the Cape about a century ago, and I only know one private individual, with the exception of myself, who grows this variety, which is the only one we can get hold of at present. I grow mine in a cold greenhouse, as near the glass as I conveniently can, so as to keep the leaves and flower-stalks stocky, and prevent them drawing. Moreover, the leaves are much more prettily marked when grown in a full exposure to the light. I use a soil of about three parts rich turfy loam, and the other part leaf-mould and rotten dung in equal proportions, or either separately, with plenty of drainage, and the pot not too large in proportion to the plant. After the bulbs commence to push their young growth, the plant should be shifted into a larger pot and fresh mould, which will last it for the season. Nothing is gained by shifting it oftener, for by the time the plant is effectually established in its first shift it will be in flower, and the sooner it is brought into a state of rest after the whole of the beauty of its noble spikes is past, the better it may be expected to bloom the following season. *E. Japonicus* flowers with me towards the end of June, and is a great ornament to the conserva-

tory for two months at least. When the principal beauty of the flowers is gone, it is gradually dried off, and packed away on its side under the geranium house stage, until it shows signs of growth in the spring, when of course it is brought into the light again. If the simple directions I have here laid down are closely followed, I can guarantee the cultivator one of the richest treats he has had for a long time, if he is not already familiar with this plant, and will follow my method in cultivating it. The year before last my largest plant had seven spikes, about eighteen inches in length; last year over a dozen spikes, and measured over two feet long from one end of the spike to the other, without reckoning the stalk. For the first month the flowers are a most lovely rosy-lilac colour, which gradually changes to a greenish colour for the latter part of the time. I think the *E. Japonica* is one of the best plants that we can have for conservatory decoration through the end of the summer, when good flowers for indoor work are scarce. The many paltry annuals which are extensively grown for that purpose bear no comparison to it, and it is much better than one-third of the orchids, and it somewhat resembles some of them. I must not forget to say that it is the most powerfully scented plant I know, and the odour is very agreeable; and also that unless the plant is thoroughly rested, like other bulbous plants, the flowers will be scarce and poor.

GEORGE GORDON.

[I saw one of Mr. Gordon's plants of *Eucomis Japonica* in the summer of 1865, and it was fully worth the praise he has now bestowed on the species, as, moreover, its condition testified it had received most skilful treatment. Many cultivators fail with this noble plant, probably because they keep it always growing.—S. H.]

Calendar.

WORK FOR WEEK COMMENCING FEBRUARY 9.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—The work must be regulated by the weather, and at this time of year the usual enemy to work is wet. If the ground is sticky, there can be nothing gained by doing anything with it; but if at all workable, not a day should be lost in planting and sowing, and preparing for various summer crops. Sometimes the stealing of a day's work in sowing a few rows of peas and beans, or the planting of potatoes, &c., may in the end make a difference of a week or two in the date of the produce coming to perfection, because if the bright day when the ground may be fairly moved is allowed to slip by, heavy rain may again stop work for some time. Our seasons do not allow of any trifling with outdoor work at this time of year, and every advantage must be made the most of. Those who have plenty of frames and other conveniences for sowing seeds under cover may push on a number of things to be transplanted to open quarters when sufficiently forward.

ASPARAGUS to be kept going in the forcing-pit for succession. Give air and light; if wholly blanched, it is not good; the sticks should be stout, quickly grown, and purple at the top.

BEANS must now be sown for main crops. For early supplies, *Hang-down* and *Mazagan* are the best; for market and rough purposes, the most profitable are the *Longpods*, of which *Johnson's Wonderful* and *Minster Giant* are the best. But for home consumption, where there is a good table, *Green Windsor* is the only sort that should be grown; it is handsome, a fine colour, superb flavour, and though less productive than the *Longpod* race, gives a good return. The *scarlet flowered* broad bean grows in the same style as others of the family; the flowers are dirty purple, dirty red, and washy lilac; the pods are plentifully produced, and serve very well for horses or pigs, but are utterly unfit for a Christian's table. We see this bean entered in some of the trade catalogues, where it is described as a most ornamental plant, and the beans of first-rate quality, both which statements are untrue. It is simply a vile thing in a garden, but an excellent thing in a field.

CABBAGE.—During the past few weeks we have been planting out considerable quantities of autumn-sown plants of *Early York*, *Dwarf Early York*, *Rosette Colewort*, *Enfield Market*, and *Sugarloaf*. We shall continue to thin out the seed-beds as occasions offer. We have also, in order to get possession of the ground on which savoy and other winter greens have stood, taken them up, and replanted them close together in batches, so that they can be drawn for use between this time and the middle of March, as in that time they are not likely to increase in size sufficient to pay for the ground, which is now wanted for rotation cropping. It would be well to sow a few sorts of cabbage now, as if they are not ultimately wanted for planting out, they may be drawn from the seed-bed for the kitchen, and make a delicious vegetable.

CARROTS.—Sow *Early French Horn* on warm borders, and thin as soon as up.

CAULIFLOWERS in seed-pans to be thinned out, and potted singly in rich light soil, or planted out in beds in frames. Sow again if likely to be wanted.

CELERY.—Sow for the main crop. Early sowings to be pricked out on beds in frames. The best way to make these beds for forwarding celery plants is to prepare a hard surface by beating; then lay on it three or four inches of a light rich mixture, consisting chiefly of rotten dung. Plant in this, and the plants will make abundance of fibres, and lift well for final planting out. Hollowness and bolting are caused by the too common practice of starving and checking the plant in the early stages of its growth, and when sown very early it is most likely to suffer a check because of the want of convenience to keep it growing until the season is sufficiently advanced for planting out. Therefore, where appliances are few, the best celery is likely to be had by sowing comparatively late—say in the last week of March.

LETTUCES required as early as possible should be pricked out from the seed-boxes into a sweet and gentle hotbed. To secure fine lettuces, the plants should suffer no check, but be grown quick, and in a rich moist soil. Therefore do not plant out any except cabbage kinds in open

quarters yet, as the check will prevent them hearing well. Sow again: the *cos* varieties are best to sow now, as they are so much more prized in England than the cabbage kinds for summer use.

Flower Garden.

ALPINES require care now that many of them are growing or coming into flower. Those that do not need repotting will be benefited by removing a little soil from the top, and replacing it with fresh sandy peat or sandy loam. Plants that make offsets freely may be increased now by division, but it is not a good time to propagate any kind of alpine from cuttings.

DAHLIAS must be kept going now where any quantity of stock is required. It is the common practice of the best growers to destroy the first gross shoots that the roots produce, and wait for the next crop for cuttings, the object being to obtain plants of less robust habit than the first growth would produce. The cuttings are most easily managed. Take them off when three inches long, pot singly in smallest pots, and put in a good heat, and they will root almost instantly. Trade growers stick them close together in beds of sand in the propagating house, and pot when rooted, but that wholesale way is not needed in private gardens.

LAWNS may be made at any time, provided the weather is neither burning hot nor severely frosty. Such moist, mild weather as we have had for three weeks past would be as good for laying down grass as any, provided the work could be done properly at intervals between the heavy rains. Where it is required to lay down turf, the sooner it is done now the better. Grass seeds may also be sown now, but the safest and most expeditious way is to obtain a fine turf, and have it put down by men used to such work. The result is a lawn at once, for use and enjoyment.

DECIDUOUS TREES of all kinds not yet planted must be got into their places without delay. Should frost occur, planting will be delayed still further; and if no frost, the trees will be so advanced in growth as to be greatly injured by the process of lifting, to say nothing of the progress they will make in the next few weeks in cutting established in their new quarters.

HARDY CLIMBERS planted now in well-prepared borders will have a good chance of making a free growth this season. Climbers doing badly may, if in a good soil and suitable position, be cut down close to the ground with a view to get a strong free growth in the coming season. Of course, if they are in a wet or starving soil, cutting the plants down will do no good.

ROSES.—Put a heavy mulch on plantations not yet dressed, and proceed with planting not yet finished.

Fruit Garden and Orchard House.

ORCHARD HOUSE.—If this has been crowded with plants not properly belonging to the place, owing to the severity of the winter, it is now time to think of clearing them away, for the fruit trees will be pushing soon.

VEGETATION is now undergoing the seasonal change from a state of torpor to active growth. The phenomena of outdoor life have their analogues in plant-houses, and no matter what is the natural climate of plants, they all more or less conform to the order of seasonal influences under which they are placed in this country. No doubt the peculiar actinic properties of ordinary daylight at this time of year have very much to do with the renewal of growth by all kinds of vegetation. That it cannot be owing merely to degrees of heat and moisture is tolerably certain, seeing that in plant-houses the degrees of heat and moisture are at the command of the cultivator. However, to deal with matters of fact: plants of all kinds under glass are now growing; very many orchids are starting; hard-wooded plants are making new wood; numbers of fine things are pushing into flower, and on every hand the cultivator finds fresh work to do. Success in plant-growing can only be assured by studious waiting upon nature. When plants commence new growth without being subjected to any special stimulus, the cultivator should take warning that they want help, and all such indications should give the key for the right moment to repot, or to refresh with top-dressing, to prune, to stop, to divide, propagate, &c., &c., as the case may require. The object of this note may be summed up in a word: it is time for plant-growers to be awake and active, to take advantage of the increase of solar light and heat, and especially to promote growth under the best of circumstances, so that new leaves and new roots may have the best of food from the first, and not be half-starved for some time before their requirements are thought of.

Greenhouse and Conservatory.

GREENHOUSE AND CONSERVATORY should be gay now with various bulbs—Chinese Primulas, Cyclamens, Cinerarias, Cytisuses, Camellias, Daphnes, and other spring flowers. Any stove plants brought into the conservatory must be guarded against a chill, and they will all bear a lower temperature than they have been grown in if kept rather dry. This treatment will preserve their beauty for a long time. The temperature of houses in which plant are growing may be increased now, for vegetation is active. Most soft-wooded plants will now become infested with aphides, unless well taken care of: good cultivation keeps such things away, and it is certain they soonest visit plants that are half starved and quite stifled.

Forcing Pit.

CHERRIES are considered the most difficult of hardy fruits to force; add perhaps the cause of the difficulty is fear of ventilating. If they are kept too close, or too wet, or too hot, they resent the injustice more readily than any subjects of the same class; they are, in fact, more capricious than peaches. The trees ought now to be in bloom in a rather dry airy house where the temperature averages 50° to 60°. They never do so well as in houses where there is air admitted below the pipes, so as to allow of free ventilation without causing a chill, as the air, passing over the pipes, gets warmed before circulating through the house. Sudden variations of temperature will cause the flowers to fall before fertilization takes place, and after the fruit is set too much or too little moisture at the roots will cause the fruit to fall like a shower of hail. Cherry trees lately put in and just starting to be freely syringed.

CUCUMBERS in the fruiting beds must be kept moist above and below, to promote a free growth. Any fruits that show before the plants are tolerably strong, nip out. By the time fruit may be allowed, the hills will want earthing up; use nice light loamy stuff, vegetable fibre being preferable to animal manure, though a little thoroughly decayed manure may be added to advantage. If there is a good heat in the bed, give a little air all night, unless the weather is too severe for such a risk; indeed, a gentle circulation of air is at all times desirable. As soon as

they begin to fruit, stop regularly one joint beyond the fruit; if this is not done, the plants soon become a mass of confusion, but it is a simple affair enough.

PEACHES that have set their fruit must not have liquid manure until the stoning period is past, which may be known by the sudden increase of the size of the fruit, after remaining stationary some time; also by the increased quantity of fruit that falls then. But the stoning period past, let them have the benefit of rather strong manure-water of the same temperature as the house, and it had better be a few degrees warmer than cooler.

PINES advancing in fruit must have liberal heat and moisture. The best manure-water is a solution of soot, but we prefer to give them nothing of the sort, as if they are grown in a suitable soil, and have proper attention in respect of heat and moisture, fine fruit can be produced without stimulants, which sometimes cause the fruit to be black in the centre, so that the finest looking fruits are after all the least valuable. At any rate, if stimulants are used to get up large specimens for exhibition, let great caution be taken to guard against overdoing it. Pot succession plants, and give the whole stock more room for a circulation of air amongst them.

STRAWBERRIES for succession to be taken in. Never place them in a high temperature at all, and prepare them if possible for the forcing pit by putting them into a cool house or pit for a week previously. Bear in mind the necessity for good food, and place the pots on a bed of dung into which they can root through the pots, or put the pots in pans filled with quite fresh short manure, or fat half-rotten stuff from the heap.

VINES may now have a rise of temperature, say 55° to 60° by night, and 65° to 70° by day. Thin away superfluous bunches in good time, and also thin out the berries of the bunches that remain, but this last job must be done at twice rather than once, and better three times than twice if there is no rough handling. To preserve the contour of the bunches, and afford room for the berries to swell, work the scissors into the centre so as to remove the inside berries, as well as reduce the number throughout. Practice and observation will alone serve as teachers in this sort of work; all that can be done here is to suggest the procedure that is desirable, and remind cultivators of what is to be done.

Stove and Orchid House.

BEGONIAS require to be repotted and started into growth. A nice friable mixture of loam, peat, and leaf-soil should be used. Large old rhizomas may be cut back, and they will break from below if aided with a moist heat; but if kept cold and wet after the knife has been used, they will be liable to rot.

GLOXINIAS have been frequently advised upon of late. There is still good time to deal fairly by them. There can be no better soil than a mixture of equal parts mellow loam, peat, and leaf-mould; we have grown them well in equal parts mellow loam and cocoa-nut fibre refuse. It is important to use the compost moderately moist, and give no water till they are actually growing. Press the roots down into the soil, sprinkle a little fine stuff over them, and then put them into a moist heat at about 70°. When advanced a little, pot them, and again give them a nice heat for a week, after which place them in an intermediate house where the temperature is about 60°. If pushed on too fast, the flowers are weak in colour.

MUSA CAVENDISHII.—When well treated, this is one of the fastest growing plants of the stove; but is not always so, because cultivators starve it. The soil cannot be too rich, but it must be sweet, and very light and porous, as the plant requires abundance of water. Equal parts of the most fibrous part of well-decayed turfy-loam, sweet leaf-mould, and quite rotten hot-bed dung will answer admirably, and there must be perfect drainage. After the shift, the plant must have a bottom-heat of 80°. Suckers will produce fruit within a year of taking them off the parent plant if kept going in a good heat with plenty of moisture.

ORCHIDS will now want much attention; some must be repotted, re-blocked, and otherwise assisted as the season of their new growth approaches. Those not to be shifted may perhaps be benefited by a little fresh peat or sphagnum. After any disturbance of the roots, give them the aid of a little extra heat and atmospheric moisture, but do not water them much at the roots until they begin to grow.

Correspondence.

FROZEN PLANTS AND FAILING BOILERS.—In my travels about as a representative of a hot-water firm, I have seen some strange things lately. During the tremendous frost of January 3, 4, and 5, boilers took to cracking, and pipes to bursting, and many a valuable house of plants was put to such risks as made their owners tremble, and put gardeners in a terrible flutter. I saw a case of this kind—a collection of orchids, the value of which I am not competent to estimate, and about which I made no enquiries, for I knew it to be one of the most celebrated in the country, and that was enough for me. Well, on the dreadful Friday night the boiler gave way, and to keep frost out, ironing stoves, charcoal stoves, and every portable heat producer that could be begged or borrowed in the district, were collected and set to work, and these were supplemented with candles wholesale. The collection was saved, though dust and cold have left their mark upon them for many a day. All the following Saturday, all Saturday night, and all Sunday, bricklayers and smiths were at work, and by hook and by crook the boiler was got out and another set in its place. The number of such disasters that occurred made quite a joke of the frost, for while it brought business to those who were glad of it, the proof was afforded that plant growers do not yet know their own interests, or they would never trust their valuable collections to boilers that may break down at any time, with no reserve in case of such accidents. The "one-boiler system" is all very well while things go quietly, but if the one boiler fails where are you? Echo answers, "Where are you?" I would not trust a good range of houses to one boiler if you gave me the boiler for nothing. I would never have less than two, and I know that the additional expense in the first instance would be more than compensated by the additional safety. I think it well to give you an account of what I saw in the garden of an amateur who has made his mark on horticultural affairs. In this garden several houses are heated by one boiler, a capital upright cylinder. On the night of the 3rd, the head gardener, a generally trusty and careful man, took care to look after the fires himself. He did everything well enough except the feeding of the cylinder, and this he choked. In fact, he stuffed in as much good fuel as he could, and then put a little dusty

rubbish on the top, so as to fill up the feed-hole, and stop the draught entirely. This was done that he might go to bed and know all was safe till the morning. The simple result was the fire went out, and next morning the astonished proprietor, who made a survey before any of the hands came to their posts, found the thermometer down to 20° in houses filled with bulbs, geraniums, greenhouse ferns, palms, and other subjects of the same degree of tenderness. In a few minutes, the head man came in a great flutter, the furnace was cleared out, and the fire set going again. The master made but little complaint, but being a cultivator in the proper sense of the term, he kept a watch. In about two hours' time he sent for his factotum, and asked how the fire was going. "Oh," says Factotum, "all right; I've nearly got the frost out." The master naively replied, "More fool you, if you put my property in such jeopardy by one folly, don't make it worse by another." His fear was of course that there would soon be a roasting heat. So he went down himself, put in the damper, put some rubbish on the fire to check the draught, and by proper management kept the temperature in the houses heated by this boiler as nearly as possible at 32° for twenty-four hours, and then allowed it to rise slowly to 35°. Lachenalias with their flower-spikes three inches long were frozen hard; *Latania Benrbonica* and *Chamaerops excelsa*, ditto; geraniums of all sorts, ditto; yet not a leaf was hurt. The gentle thaw saved them. To repair a damage is the next best thing to avoiding it. HOT-WATER.

PLANTING A SET OF BEDS.—Your perusal and reply through the GARDENER'S MAGAZINE of the following will be greatly esteemed. The above figures are made by small posts of wood 6 or 7 inches high each tier. My system in planting the past year was the following: No. 1, Geranium Cloth of Gold and *Lobelia speciosa*, alternately; No. 2, *Lobelia Paxtoniana*, thickly; No. 3, *Geranium Stella*; No. 4, Geraniums Bijou and Flower of the Day. I and others were pretty well pleased with it, but as I

have a desire to do it better, I make my request to you. One thing I may mention, I wish to put Mrs. Pollock in centre tier (4). What can I put in No. 3 to correspond? Being baffled, I intended to put Mrs. Pollock in No. 1, but would much rather have her in No. 4. Not having much room for bedding, I should like to do the thing well. If you could, suggest how to plant these four beds first with Pollock in No. 1, then in No. 4.

AN AMATEUR.

[In considering a case of this kind, we are obliged to make something of a guess at the means of the inquirer, to avoid recommending anything that might prove too expensive. In the present case, we suppose our correspondent to have a stock of each of the plants named, and desirous to make the most of them. If the two figures are under view at the same time, as represented, there must be an agreement between them in general colouring. No. 1 with Cloth of Gold alone would be more telling than mixed with *Lobelia*; but *Lobelia speciosa* would make a fine blue line for a boundary to it, and allow us to use Flower of the Day in No. 2. We suppose that 1 is a higher level than 2, and that the *Lobelia* would partly hang over the line of wood that defines the shape of 1. For the other figure, Mrs. Pollock would make a fine effect in 4, if bounded by a sharp line of *Lobelia speciosa*, as in the crescent; then a belt of *Stella* all round, and an edging of Bijou. But if these figures are flat, the *Lobelia* would be overtopped, and we must adopt another plan. Say Cloth of Gold in 1, dividing belt of *Stella*, next a line of Flower of the Day, and outside margin of *Lobelia speciosa*. Mrs. Pollock in 4, with a belt of *Stella* to define the circle, then a single circle of Bijou, and a broad and very bold margin of *Lobelia speciosa*. In each of these schemes we throw out *Lobelia Paxtoniana*.]

ENGLISH-GROWN HYACINTHS.—I have half an hour on my hands this evening, and I have been thinking that I cannot occupy it better than by describing to you the mode in which I cultivated hyacinths some years since, so as to procure from them a much finer bloom than that from imported bulbs. As far as my experience has gone, I think that these beautiful things may be brought to a much greater degree of perfection in the rich loam of this country, aided by heavy applications of manure, than anything we have yet been accustomed to see brought into this country from abroad. I was induced to try my hand with them because I found I could but seldom get hold of bulbs of any of the yellow flowering varieties that would throw up satisfactory trusses of bloom. The old Prince of

Orange, and some two or three others, which at that time (some twenty-five years since) comprised the whole of the imported varieties of this (to my taste) beautiful section, I have succeeded in bringing to such perfection as to obtain from them trusses of bloom as fine as any I have ever seen produced by the finest bulbs of Grand Vainqueur (white), Nimrod (blue), or any other similarly large-trussing varieties. The length of time necessary to produce good flowering bulbs is at least three years. When I first began, I selected a small spot containing not more than three superficial yards; I threw out the soil to the depth of two feet, and placed at the bottom of the trench six inches of rotten manure, then six inches of earth, then four inches more manure, and then filled in the whole of the soil. This was the first week in September. The roots of hyacinths begin to move by this time. As soon as I filled in, I selected the strongest offsets from the different varieties I had grown the previous season in pots, and planted them at a depth of four inches, nine inches from row to row, and five inches apart in the rows. This gave me from sixty to seventy roots in the three square yards. When they were an inch or so above the ground, in the middle of February, I stirred the surface of the soil between the rows; this was of great benefit to them, as to all other growing crops. They required no further attention till the trusses were developed, when I divested the flower-stems of all the buds excepting the top one, for the purpose of drawing up the sap. This process conduces very much to the strong development of the foliage, and consequent invigoration of the bulb. As soon as the foliage was fairly decayed, I took them up, laid them in a cool, airy tool-house to dry gradually for a fortnight, and then put them away in a drawer till the first week in September again, when the bed in which they had been planted underwent exactly the same preparation as that before described. At the same time a similar piece of ground was prepared for a second batch of offsets, to undergo precisely the same process, and in the following year a third batch as above. At taking-up time in the third year, I found most of the bulbs well grown, some of them surpassingly fine. Some few of them required still another year's growth, but as a rule, at the end of the third year they were so firm in texture, and, in consequence of my having dried them well, so thoroughly ripened, that I obtained a most satisfactory bloom from them the following season, and by keeping three beds, one under the other, I was enabled to make a capital display of these beautiful flowers from Christmas till the end of April. I ought to say, in justice to my employers, who were exceedingly kind and liberal, that all the years this process was going on we bought as many bulbs as heretofore, my object being in the adoption of this plan to obtain good trusses of bloom from varieties I could not get to bloom well from imported bulbs, and which were with me special favourites. My impression has long been that we get all our imported hyacinths one year sooner than we ought. If the Dutchmen would give them another year, we should have a constant importation of prodigies, instead of the feeble flowering specimens of which the present importations so largely consist. In all fairness, I ought to say that I got the idea how to manage these things from an early number of the *Floricultural Cabinet*—I cannot say what date, and at this distance from home I cannot lay my hand on the number; but I would say that the younger readers of your GARDENER'S MAGAZINE would be much interested and instructed if they could lay their hands on the first six or eight volumes because of the large number of valuable articles to be found in those numbers from the pens of first-class gardeners. Through some accident my last paper was dated from a place which does not exist; my whereabouts at the present time is *Knockholt, Kent*.

WILLIAM CHITTY.

GAS IN CONSERVATORIES—CAMELLIAS UNDONE.—About four or five years ago, the conservatory I have under my charge was by my employer ordered to be lighted with gas, which was done, and lighted up in the evening for a week or so; and although I gave a little air at the same time, fearing evil consequences from the drying effects of the gas, I was sorry to see the camellia buds drop by hundreds. Of course it was seen that it was caused by the gas, and there was to be no more Christmas tress nor gas either. But two years after it was hinted that they would like the conservatory lighted again when Christmas returned. I was sorry to hear that, but could not say that it should not be, and calmly answered that camellias and such things could not stand gas. But it was to no purpose—it must be lighted; so the gas-fitters were set to work, and unfortunately they accidentally left one of the tubes open all night, so the conservatory was filled with raw gas from the main all night. So judge my feelings when I opened the door next morning. I went to one of the camellias and gently shook it, and buds and leaves and all came peppering down like hailstones, and so on all through the conservatory. Two years have passed away, and both last year and this I am very much amazed to find that the camellias still drop their buds—so much so that I have very few left. Now I shall feel greatly obliged if you can give me your opinion as to whether the buds dropping is attributable to the gas still, or not. The camellias, with the rest of the conservatory, are well attended by myself, for the plants are neither allowed to be dry nor wet beyond the extreme. As for firing, I never allow the temperature to rise above 40 or 45° all through the autumn and winter, and give air in accordance to weather when it is required. Generally the camellias have not been potted for some five years, as the gardener I succeeded put them in larger pots than I should have done. Do you think that the water I use, which is obtained from a lead cistern, has anything to do with the grievance now? or do you think that repotting would have the desired effect? I must not forget to say I syringed them every day in the morning after each night of the conservatory being lighted.

J. T.

[We are by no means prepared to pronounce a decided verdict on this case, for we happen to know a few lofty conservatories that are frequently lighted with gas on occasions of festivity, and camellias, azaleas, oranges, and acacias, with other conservatory plants, take no harm. But we are greatly obliged for the communication, as the subject of lighting conservatories is becoming more and more important every day, and it is desirable that we should arrive at a clear knowledge of what in this matter may be really done. In any case, lighting a conservatory is attended with some risk, for if the weather is frosty at the time, it is scarcely possible to give air; indeed there ought to be a house or shed attached to a conservatory which is supplied with gas, through which a current of air may be transmitted, and heated to a proper temperature, for the ventilation of the conservatory. Now as two years have elapsed, and the camellias still drop their buds, there is something like negative evidence that the gas was less hurtful than seemed, because the plants ought by this time to have recovered. The probability is therefore that the plants want repotting, and we advise J. T. to get them into smaller pots as soon as possible, and set them growing in a mild moist heat.]

Replies to Queries.

Vine Border.—Amateur.—You say the drainage is good and the soil light; we should say in that case there is no need to concrete the border, especially for ground vinerias. If the border is to be raised, and you can obtain a few loads of turf as easily as loam, by all means have it.

Name of Fern.—W. C. K.—Your sweet-scented fern is *Lastrea æmula*, one of the prettiest of all the European filices.

Frozen Plants.—R. Baxter.—It is quite too late now to do anything for the plants that were frozen. Should you be caught again, and the frost gets in, put mats over the glass, or adopt some other means to darken the house, and keep the temperature as near 32° as possible for at least a day, and then let it rise very gradually. It is a common practice with gardeners when a pit full or house full of plants is frozen to syringe them with cold water. But we cannot recommend this plan, having seen it followed by the death of valuable plants that probably would have survived if thawed gently and in the dark. Such things as hyacinths and tulips do not take much harm from a few degrees of frost.

Index for 1866.—R. W. B. P.—The index accompanied the number for January 6, 1867; not a single copy left the publisher without it, and no extra charge was made; in fact it formed part of the ordinary weekly issue. Subscribers who take the work in parts will find the index in the part published on the 1st of February; it was not ready in time for the January part. We really cannot be responsible for the absence of the index in any case, and as to making an extra charge for it, the man who does so either makes a mistake or commits a fraud.

Plants for Case out of doors.—H. B.—In the event of a very severe frost, tender plants in a case measuring only 4 feet 6 inches in length would probably be killed outright, in spite of the best arrangements for heating. In fact, small structures of every kind exposed to the weather are most difficult to manage in this respect. As the position of the case is perfectly shaded, a selection of hardy ferns would perhaps be most suitable, and a few mosses could be introduced to surface the ground. The following are distinct, handsome, and hardy, and all except the last two named are evergreen. Those likely to suffer in a severe winter are marked thus *.

British: *Asplenium adiantum nigrum*, *A. marinum*, *A. trichomanes*, *Ceterach officinarum*, *Lastrea æmula*, *L. dilatata*, *Polypodium vulgare* and its varieties, *Polystichum aculeatum* and varieties, *P. angulare* and varieties, *Scolopendrium vulgare* and about a hundred of its varieties, of which the following are the best—*bimarginatum multifidum*, *contractum*, *cornutum*, *crispum*, *cristatum*, *digitatum*, *glomeratum digitatum*, *laceratum*, *ramo marginatum*, *ramosum*, *undulato lobatum*, *Wardii*. **Exotic:** *Adiantum cuneatum**, *Asplenium ebeneum*, *Camptosorus rhizophyllus*, *Cyrtomium carotoidesum*, *C. falcatum*, *Dennstaëdia punctilobula*, *Lastrea atrata*, *L. cristata*, *L. frondosa*, *L. Goldiana*, *L. intermedia*, *L. marginalis*, *L. opaca*, *L. Sieboldii*, *Lomaria alpina*, *L. Chiliensis*, *L. Magellanica**, *Polystichum acrostichoides*, *P. falcinellum*, *P. vesutum*, *Pteris esculenta**, *Woodwardia radicans*, *W. orientalis*, *Asplenium bulbiferum**, *Pteris flabellata**, *P. cretica**, *Davallia canariensis**, *Platyterium alaicorne**, *Todea hymenophylloides (pellucida)**, *Plebodium sporocarpium**, *Onoclea sensibilis*, *Osmunda Claytoniana*. To these might be added *Equisetum sylvaticum* and *E. telmateia*. A few of the small-leaved variegated ivies might be useful to train up here and there by means of wires next the glass; all the ivies thrive in cases.

Nardoo.—Sybil.—It is quite a mistake to suppose that this interesting plant cannot be cultivated. We saw a fine pan of it a year ago or so at the Regent's Park Botanic Garden, under the care of Mr. Robinson, and it had a very beautiful appearance, resembling a large-leaved Oxalis. The pan was filled with water, with a little soil covered with pebbles at the bottom, and the house in which it was kept was heated to intermediate temperature.

Trees injured by Frost.—W. B.—Your cedars will be none the worse for the frost in three months' time. Brown as they are, the buds are sound; and indeed in many cases they appear already anxious to start. The *Grisebinias* and *Cotoneasters* will probably renew themselves from the base. Do not be in haste to dig up and burn. You have probably not lost much.

Cutting Seakale.—Constant Reader.—The kale sent to market is cut with about an inch of the root attached, to facilitate the carriage of it, and keeping the heads together complete; and usually the roots are destroyed after forcing, and the loss of an inch is of no consequence. The regular market growers sow every year, or raise plants from root cuttings; therefore their practice need not guide the cultivator in cutting from permanent beds. In cutting from permanent beds it is best to pass the knife close over the junction of the stem with the root, and generally speaking there is a good inch of white stem firm enough for the purpose of keeping the heads complete until they go into the hands of the cook, who must remove the root part if the gardener cuts so low as to have any of it. The advantage of this is that the buds of the crown are left for the next growth. But it will not injure a permanent bed to cut deep, even to the removal of an inch of root, for the root will throw out crowns from any part, as may be seen on taking up an old stool, which will be found to consist of several underground stems forking from a depth of three to six inches from the top, forming a series of crowns.

Wallonian Case.—Fence House.—We really cannot give any information on the subject. We have heard that the manufacture of these cases has been some time discontinued.

Lapageria rosea.—G. Gould.—We have frequently described the mode of treating this plant in England, but we are not so well prepared to say how it should be treated in New Zealand. Doubtless there it will do to train over a trellis in front of a house, or cover a garden bower. The treatment under which it best succeeds with us is planted out in a bed of sandy peat, allowing about a square yard of soil for a plant; the bed to be two feet deep. A cool greenhouse is the best place for it, as it will never stand heat nor frost. It is trained along the roof on wires or chains, in rigid lines or elegant festoons, as suits the whim or convenience of the cultivator; and from the middle of May to the middle of August it has copious and frequent supplies of water. Nature does the rest when these points are attended to, and this glorious plant produces myriads of its wax-like flowers, and ripens abundance of seeds. In the purchase of plants, seedlings are always to be preferred. Plants from layers sometimes grow well, and sometimes do not grow at all.

SUBSCRIBERS TO THE GARDENER'S MAGAZINE who desire to extend its sphere of usefulness, and are willing to interest themselves in promoting its still wider circulation, can materially further this object by sending to the publisher the names and addresses of persons they think are likely to become subscribers, who will forward to each a SPECIMEN copy free. A stamp must accompany each name and address sent, to cover the postage of the specimen copy.

The Gardener's Magazine.

SATURDAY, FEBRUARY 16, 1867.

EXTENSION versus RESTRICTION is becoming the question of the day for fruit growers. We have perhaps said enough on the advantage of extension in the treatment of the vine, and we may now very properly ask if the arguments used in favour of allowing vines to cover vast spaces, are not applicable to wall trees generally, and perhaps to all kind of fruit trees to be found in our gardens. The restrictive system is attended with admirable results up to a certain point, and then it breaks down altogether. Hence where numbers of vines are grown together, and they are forced into early productiveness, there must be a system of renewal always in action, for the precocious plants are soon used up, and their places must be supplied with successors as fast as they vacate them. The result of the rapid system is satisfactory with exceptions, and one of the exceptions is its comparative costliness. In truth, when a well-doing vine is allowed to run freely root and branch, it ceases to be costly; and the rent of the house it occupies is the only serious item in its keep. But it is far different with a collection of two or three hundred vines in a house which might otherwise be filled with one; there is an immensity of work, there is perpetual outlay, and the best samples grown are rarely equal in all points to the productions of vines of many years' standing, and that are in perfect health and almost unrestricted as to the space they occupy.

To establish a parallel case in respect of wall trees will be no difficult matter. We propose to our readers to investigate the case for themselves, and to form their own conclusions. Suppose every one interested in this question will first consider his own case, comparing his great old trees, if he possesses any, with trees that are crowded and restricted, and fairly estimating their average production as compared with the actual space of wall covered. Next let the inquiry be extended. Some gardens in the district will be noted for peach, apricot, and plum trees covering immense breadths of wall. Let it be ascertained if, generally speaking, these make a fair return for the space they cover, and let them be fairly compared with equal breadths of trees confined in limits. We have no doubt at all as to the result of such inquiries, and we anticipate that in at least nine cases out of every ten, competent judges will give the verdict for the big trees, and pronounce the miniature trees of every kind to be the toys of the fruit garden. We have not the temerity to assert that restricted trees produce no fruit, for to establish the truth is our only object, and we see too much of the perfection to which toy cultivation has been carried to pronounce it a failure altogether. It is far otherwise. Grape vines of a year old show noble bunches; pear, plum, and apple trees two or three feet high may be seen covered with handsome fruit; even the walnut and the mulberry, the least tractable of fruit trees, submit to the dwarfing system, and become precociously fruitful; and a single cordon of peach or nectarine may be encouraged so as to be studded with fruit of most excellent quality. But none of these cases, interesting as they are, suffice to determine the question before us. Which is the most profitable in a series of years—say five, ten, or twenty—for a given space of ground and a given outlay, the natural (extended) or artificial (restricted) treatment of fruit trees? On the one side, everything is in favour of a profitable result; on the other side, there is much against it. If the soil and climate are adapted for the trees selected, a free growth will always favour a healthy condition, and in due time the excessive vigour will decline and the tree assume its proper fruitful condition. It is worthy of notice that we know little of disease or of the mysterious deaths of principal branches of wall trees that have ample root space and are allowed to expand themselves freely above-ground. Where gumming, withering of the points of shoots, and other such ailments occur, we shall generally find that the borders are cropped and the trees thereby robbed of what is due to them; that between the standards dwarfs are introduced; and that the trees are all cramped and crippled in order to compress a great number within a too limited extent of space. Wall trees of vast extent are as a rule vastly productive, and to say that they are long-lived would be a solecism, for their size is a proof that they have lived long already. Longevity cannot be counted among the prevailing qualities of miniature trees of any kind. To fruit apple or pear trees in the second or third year from the putting on of the graft is a feat worth

No. 94, NEW SERIES.—VOL. X.

commendation, but none of these precocious trees will, even in respect of quantity of production, match large old trees covering the same extent of ground as a given number of miniatures selected for comparison. Indeed we have on several occasions, when recommending miniature trees to the attention of amateurs, urged the extreme fruitfulness of large trees as an objection to them, for in many cases a dozen each of a dozen different sorts of fruits would be more prized in a small family than several bushels of one sort coming ripe all at once, and lasting only a short time in good condition. Where variety is desired, and where there is a mania for collecting, and where as much practice as possible must be adapted to a limited extent of ground, miniature fruit trees are invaluable. But we must not be led astray by delusive examples; if we are to consider the several systems as to their whole results, there cannot be a question that dwarfing the head, restricting the root, and inducing early fruitfulness by pinching, tends both to shorten the life of the tree, and fix within rather narrow limits the possibility of its productiveness. What we gain in time is perhaps more than paid for in the end by liability to disease, occasional failure of fruitfulness, and shortness of life. All this is in accordance with the soundest philosophy, for after all we are only contending that the most profitable method of fruit culture is that which puts Nature out of her wonted course the least possible.

MR. MACNAB HAS REVIVED, in the pages of *The Gardener*, the much-disputed question of the policy of pruning coniferous trees. When so able an advocate takes up an exploded doctrine, it appears to the usual on-looker as if no explosion had ever taken place, so admirably do the dislocated parts fit together again. Mr. Macnab directs attention more especially to the pruning of the Deodar, and describes the process as consisting of a reduction of the young tree to symmetrical proportions, and occasional after-stopping to check any unruly growth or outbreak of excessive vigour in any part of the tree. He says, "after being once properly cut into shape, it is seldom necessary to give the Deodar any after-pruning, unless to remove duplicate leaders that may be forming." Further on we are assured that "those trees which stood the severe winter of 1860-61 had been fully pruned at an early period." No one can dispute that in many cases the Deodar may be much improved by judicious pruning, but we should greatly fear to see pruning practised on this naturally graceful tree, this most elegant of all coniferous trees, by any but the most cautious and experienced hands. We occasionally meet with specimens that are disfigured by side branches of extravagant growth that contend for the mastery with the proper leaders. In such cases, pruning is a matter of the utmost importance. If the abnormal growth is detected in time, one good stroke of the knife may be all that is required; but if it has proceeded so far that the cutting out of the usurper would make a great gap and a great wound, its reduction should be accomplished by shortening in at first, and removal subsequently. So also, no doubt, judicious pruning will promote perfect symmetry, so that specimens of 10 to 30 feet in height may be as regular as if modelled to geometrical proportions; but it does not follow that such perfect symmetry is desirable. If we but wait, we shall see the most irregular Deodar acquire by degrees a grace and finish only to be matched by another Deodar of its own age, and similarly circumstanced as to soil and climate. It is about the last tree in the world that needs pruning to render it elegant; and to some tasteful eyes, its occasional irregularities are rather in its favour, for excessive symmetry is near akin to formality, sameness, and insipidity; and we really do not want to see ornamental trees regulated to such a nicety as to serve as illustrations of the problems of Euclid. It only needs another step to lead us into the absurdities of topiary, and we beg Mr. Macnab's pardon for looking so far ahead, for we suppose the clipping of a Deodar into the shape of a malt-kiln or a corkscrew would horrify him as much as anybody. We hope there will not be much pruning of Deodars, or of any other coniferous trees, practised in consequence of the persuasions thereto by our able Scottish friend. There is one comfort, that this tree grows freely and soon recovers even from injudicious pruning; but it is not desirable to say much about the advantage of pruning it at any time, because of the probability that the slashing and dashing class of pruners will take heart and murder all the Deodars they can lay hands on. It is the saving of noble coniferous trees in English gardens that it is generally considered "they will not bear the knife." That is a wholesome doctrine, and we are rather sorry that Mr. Macnab has attempted, even in respect of one coniferous tree, to call it in question, or suggest doubts of its universal application. As to the tying up of the leaders of Deodars, or any other trees that have drooping leaders, it is a ridiculous practice, and we heartily join with Mr. Macnab in saying it "ought to be avoided."

MR. MECCHI has again charmed an agricultural audience with one of those spirited semi-autobiographical essays on the practices and prospects of English agriculture, which it is his wont from time to time to make public. On this occasion the members of the Faringdon Farmers' Club were the specially favoured persons, but the press has sent the paper far and wide, and we may hope that, like bread cast upon the waters, it may be found after many days. Mr. Mecchi does not budge an inch from the ground he took up long ago in respect of the capabilities of the soil of this country, and the manurial recourses that are within reach of agriculturists everywhere. In respect of wheat production, he says, "We are dependent on foreigners for an average annual importation of 6,500,000 quarters of wheat alone (that quantity being increased this bad harvest to 8,000,000 quarters), while our average annual home-growth of wheat is only

12,000,000 quarters—12,000,000 of quarters over an area of nearly 60,000,000 of acres! Can anything that I may say add to the disgrace and humiliation of such a statistical fact, seeing that we are so overdone with surplus capital that our loans to foreign nations, independent of other foreign investments, may be probably 200 millions sterling, and that in home railways alone we have an investment of £500,000,000. Our natural production of wheat, at the average of 56s. per quarter, presents the ridiculously comparative sum of £34,000,000! This for the daily bread and annual feeding of 30 millions of people! On my poor farm of 170 acres, the annual production of wheat is more than 250 quarters, and other grain in proportion; so that if the rest of the kingdom did its duty equally with my poor soil, our annual produce of wheat, instead of 12,000,000 of quarters, might be 88,000,000 of quarters." The subjects principally treated on are the relations of landlord and tenant in respect of improvements, the transfer of land, agricultural education, farm-servants, the importance of live-stock, and the effects of town sewage. Gardeners no less than farmers will find this latest of Mr. Mechi's literary productions brimming with useful instructions, good advice, and philosophical suggestions.

THE ROYAL HORTICULTURAL SOCIETY'S PROGRAMME for 1867 announces two Spring Exhibitions, namely, on the 19th of March and the 16th of April. A show of a peculiar kind for "special prizes" is to be held on the 7th of May. On the 4th of June will commence the Great Show of the season, which is to last five days, the last of which clashes with the Great National Show to be held at Manchester. On the 2nd of July will be held the National Rose Show, and with that the society's London season will close—the show to be held at Bury being a separate affair altogether.

The obituary of the past week contains the names of two eminent promoters of the rural arts. Mr. GEORGE URE SKINNER, so well known as a collector and cultivator of orchids, and to whom *Lycaste Skinneri* and many other orchids were dedicated, died on the 9th of January, at Aspinwall, Panama, of yellow fever. He was on his way, when arrested by illness, to Guatemala, in order to wind up his connection with the commercial house of Klee, Skinner, and Co., in order to retire from business. On the 6th of the present month, died, at Brighton, the Rev. SAMUEL SMITH, rural dean, and vicar of Lois Weedon, in Northamptonshire, the author of the celebrated work on "Lois Weedon Husbandry." Mr. Smith rendered important service to agriculture, and scarcely less to horticulture, by the course of experiments he pursued to show the possibility of rendering active those properties of the soil which are ordinarily latent, but which in an active state render it highly productive. If he accomplished no more than to prove that deep and frequent stirring of the soil is as effectual to maintain its fertility as the incorporation of manure, he conferred a lasting national benefit; but he was, in truth, a master of the science of cultivation, and contributed in a most material degree to the recent advances of agriculture in Britain. Of his character, all that need be said is that he was a scholar, a gentleman, a Christian, a man of strong mind and sweet temper.

THE ROYAL HORTICULTURAL SOCIETY.

The annual meeting of this society was held on Tuesday last, at the Council Room, South Kensington—the Duke of Buccleuch, the president, in the chair. The report, read by the secretary, stated that, notwithstanding the monetary distress of the past year, the Council were able to report an increase in the amount of annual subscriptions. The sums paid by Fellows as subscriptions in 1865 amounted to £7,975 1s. 1d., but their annual subscriptions rose to £8,176 9s. 6d. in 1866. In the sources of income least liable to fluctuation, the society had made decided progress, and although the receipts from exhibitions and from daily admissions had fallen considerably below the average, the Council were of opinion that the affairs of the society, though requiring strict economy, were in an encouraging position. A deficiency in the receipts, as compared with those of 1865, was occasioned by the abolition of the cheap admissions, in compliance with the wish expressed by the Fellows at the last annual general meeting. Unfortunately, the free admissions which were granted to the public in lieu of them were not so successful as to induce the Council to repeat them. They were taken advantage of less by the classes for whom the boon was intended than by those whose presence in the gardens the Council had no desire to encourage. The Council were taking steps to get the tax removed from tobacco purchased for horticultural purposes. The education scheme for gardeners was working with success. The examinations held this year had resulted in thirteen young men receiving certificates either for horticulture or fruit and vegetable culture. Five of these gardeners were employed at Chiswick, five at the Royal Gardens at Kew, and three were from private establishments. Of those who presented themselves for examination, three had previously obtained certificates or prizes from the Society of Arts, examining on behalf of the Royal Horticultural Society; two also showed themselves worthy of election as Associates. In the arrangements for the present year the Council had been induced to try the experiment of extending the duration of the first great show to four days. It appeared from the balance-sheet that the income for 1866 was £13,179 2s. 10d., which with £5 5s. 4d. balance made a total of £13,184 9s. 2d. On the other side, the expenditure had been £10,182 0s. 2d., interest £1,951 18s. 8d., prizes £70, making a total of £12,203 18s. 10d. The liabilities of the society were £980 10s. 4d., against which the society had a balance of £203 17s. 7d. in the bank. The Chairman moved the adoption of the report, which was seconded by Colonel Challoner. Mr. Harry Chester said on the whole the report was extremely satisfactory. The Council referred with a degree of vagueness to the relations of the society with the managers of the late International Horticultural Exhibition. The society had treated the exhibition committee with great liberality, and the exhibition was a most brilliant success, leaving the committee with a large surplus in hand, which they did not know what to do with. They had given £1,000 to an excellent charity—the Gardeners' Benevolent Institution—and although they had no legal right to do that, yet he for one did not intend to dispute it. The question was, Did they intend to give a portion of the money to the Horticultural Society? A long discussion ensued, the prevailing feeling being that the society was clearly entitled to a portion of the surplus in the hands of the committee of the Horticultural Exhibition, it being understood that in case there should be a surplus from the exhibition, the society should have a portion, a minute to that effect having been recorded on the Transactions of the society at the time the agreement between the society and the committee was entered upon. The report was adopted. Lieutenant-General Hon. C. Groy, Major T. Clarke, and Mr. W. W. Buller were elected members of the Council; and the other officers having been appointed, the proceedings closed with a vote of thanks to the Chairman.

HISTORICAL AND TYPICAL ROSES.

In every pursuit, whether of art, science, literature, or politics, there arise from time to time certain prominent discoveries, or events, which serve as epochs or stand-points from which comparisons may be made and progress reviewed and determined. In applying this position to the present condition of the popular subject of rose culture as a florists' flower, it will be necessary to revert to certain kinds which have been produced during the last thirty or forty years, before which date we had only species and varieties almost all of which have disappeared from general cultivation. During this period individual flowers have been successively introduced, marking decided stages of advancement, possessing distinctive characters, and exercising important influences upon succeeding varieties. An analysis of these is essential to all who wish to become thorough masters of the gentle craft of rose-growing—certainly the most romantic and poetical department in the whole domain of floriculture.

The class of Hybrid Perpetuals is that to which the present perfection of the flower is mainly due. It is the most recent in its introduction; it is that in which the greatest improvement has been made, and to which we look for further developments of qualities verging towards perfection. For this valuable section we are chiefly indebted to a celebrated French raiser, M. Laffay, of Bellevue, near Paris, who succeeded in producing continuous blooming roses from crosses between the hybrid Bourbons and damask perpetuals and the Bourbons proper, about the year 1830. Two of them, the *Duchess of Sutherland* and *Madame Laffay*, introduced in 1839, are still roses of no common pretension, although they do not appear to have left any "bright particular star" among their descendants. *Baron Prevost*, *William Jesse*, *Dr. Marx*, *Reine des Fleurs*, *La Reine*, are a few among many also originated by the afore-named raiser. Indeed, it has been asserted that half the hybrid perpetuals known up to 1850 have owed their introduction to his skill. It is a matter for regret, as an instrument for tracing the parentage of notable varieties, that the generality of continental rosarians do not employ greater exactitude in recording both sides of the lineage of new roses. They appear to pay less attention to artificial impregnation than our own countrymen, contenting themselves with merely noting the tree from which the hips are gathered. It would be impossible under many pages to analyze all the important roses of this section which have given rise to new seminal varieties. Nor is it, indeed, necessary to mark more than a few striking examples from which the best of our modern favourites are derived. These may, perhaps, all be summed up under the types and strains represented by *La Reine*, *Géant des Batailles*, *William Jesse*, *Louise Odier*, *Jules Margottin*, and *General Jacqueminot*. The last has been the favourite parent, apparently, of most of the novelties since it first made its appearance.

Of these, *La Reine* is that which has afforded one of the longest lines of the finest specimens of light, double, globular roses, some of them, unfortunately, hard to open, and touchy as to soil and situations, but others all that could be desired—possessing, as most globular kinds do, the valuable property of keeping longer than those of looser texture.

Madame Knorr, which may almost be described as a perpetual moss without the pubescence, is one of the most beautiful and distinct of roses. It would appear from its foliage and growth to belong to the blood of *Baronne Prevost*. From this, as one parent, probably a true perpetual moss might be developed—its power of blooming in the autumn being of the first order. A fine line of novelties ought to arise from judicious crossing of this charming and elegant variety—say, with *Gloire de Dijon* or *Charles Lefebvre*.

Louise Odier (*Margottin*) must be enumerated as another of historical roses, from the numerous progeny of highly distinct kinds it has given to the world, all possessing marked characteristics of the Bourbon family. None are large, but they are well formed and globular. The foliage is rich, the wood smoothish, and of an average degree of hardiness. *Catherine Guillot* and *Modele de Perfection*, with others of the same type, called by some rosarians "Bourbon Perpetuals," are among the best modern representatives of this distinct class.

Géant des Batailles, raised from *William Jesse*, one of the marvels of its day, has given birth to a large family of seedlings—all, like their parent, possessing an uncertain habit, stumpy growth, and an incurable tendency to mildew. All of them have the most brilliant colour, but, alas, how fleeting! Even *Lord Raglan*, the best of the brood, will not endure a few hours' sun, changing its glowing hue to a dirty, foxy red. This strain had better be avoided in all but the most favourable situations, and indeed even there, now there are so many kinds endowed with superior qualities—that of high colour included.

The Centifolia type is represented by *Baronne Prevost* and its descendants; possibly, that beautiful but peculiarly incurved globular rose *Louise Peyronny* has much of this blood in its composition. *Madame Damage* and *Madame Cambaceres*, have also some affinity to the tribe, notwithstanding a more vigorous and robust habit.

H. P. *Comte de Montalivet*, from *William Jesse*, once one of the darkest of roses, constantly reappears, as in *Princesse Mathilde*, *Archeveque de Paris*, and some other very dark kinds, often assigned as seedlings to *Jacqueminot*. The petals of these are somewhat incurved, and not very double, with a maroon tinge flushed as it were over the face of the crimson-scarlet.

The two most noteworthy seed-bearers, however, of the hybrid perpetual section are without doubt *Jules Margottin*, raised by *Margottin*, and *General Jacqueminot*, raised from *Gloire de Rosomene* by an amateur, and bequeathed by him to his gardener. The first named is perhaps unsurpassable as a model of the reflexed form of rose—that is, with a very high centre, no visible eye, the interior petals small, turning regularly back, and increasing in size to the exterior circle of the flower. *Jules Margottin* is a prototype of one of the finest amongst the summer roses called *Brutus* or *Brennus*. It is a free autumn bloomer, of a fresh and lively colour, and its habit and constitution leave little to be desired. Its excellence as a parent is exemplified by the high quality of the roses it has produced—notably, *Beauty of Waltham*, *Achille Goussé*, *John Hopper*, a cross between that and *Madame Vidot*, and still more recently (by the same raiser, Mr. Ward, of Ipswich) *Mrs. Ward*, from *Jules Margottin* and *Comtesse Chabrilland*, thus uniting the globular and expanded types, producing a rose described as follows: "Beautiful rosy-pink, centre brilliant rose, very full cupped, fine shell-shaped petals, remarkably even, of great substance, thicker than those of any other rose in cultivation. As to form, no better model of a rose exists; highly fragrant, free autumnal bloomer, and vigorous growth." We know the merits of *John Hopper*, and if this should prove only as good, it will be long before, in its way, it can be surpassed.

We must next proceed to consider *General Jacqueminot*, which a Turk would probably describe as the "Father of Roses," so extensive have been his scions year after year, with no apparent present diminution of their number or popularity. The finest highly coloured roses must be referred to "the General," although it has also given rise to an immensity of rubbish. There is a remarkable peculiarity about the wood of the finest of the Generals' seedlings, such as *Senateur Vaisse*, *Charles Lefebvre*, and *Madame Victor Verdier*, which is that the wood more strongly partakes of the smooth, bright, and hard texture of the Bourbon class than their parents, reverting in that respect, and also in colour, to the original *Gloire de Rosomene*. The foliage also is dense and leathery in texture. These two beautiful roses, by skilful and well-considered combinations, will probably originate more excellent varieties still, as far exceeding the gems possessed by the present generation as they transcend the conceptions of our forefathers.

We must now glance at a few remarkable roses of other sections, and will first take *Souvenir de la Malmaison*, raised by M. Belize so long ago as 1843. Here we have a decided type assigned to the Bourbon family, but which has, unfortunately, never been improved upon; perhaps in its individual style it is not possible to do so, except as to hardier constitution and variety in colour. These are not accomplished yet in its sport, *Malmaison à Fleur Rouge*. Extra large, circular in outline, double in conformation, odoriferous in perfume, free in growth, it appears shy in bearing seed, and must be perseveringly fertilized in warmer climates than our own to produce new varieties. Could we obtain roses like this possessing the colour and constitution of Charles Lefebvre, what an admirable strain would be the result! The attempt to realize such, however, would not be a profitable trade experiment; it would require too much time, and could only be carried out by the patient perseverance of enthusiastic amateurs.

It is to be regretted that so much confusion has been allowed to exist between the classes Tea and Noisette, which have become so intermixed that in numerous cases it is difficult to decide to which of the divisions certain kinds ought to belong. The mere characteristic of scent, a very erroneous and insufficient test, has sufficed to determine the allotment. That very excellent and distinct rose *Gloire de Dijon* is a striking example of this mistake. With the exception of its perfume, it has certainly nothing in common with the ordinary teas, and how it became endued with that it is difficult to discover. Its vigorous habit was probably derived from some strong-growing Bourbon such as *Paxton*. *Gloire de Dijon* has afforded some few seedlings, such as *Gloire* or *Belle de Bordeaux*, which, retaining its tea-like odour, bears much resemblance in other respects to certain of the hybrid perpetuals. *Gloire de Bordeaux*, a disappointment at first, seems scarcely yet understood, and is consequently avoided. Yearling plants do little good; when matured by two or three years' growth, however, the variety is a constant bloomer, and a highly useful adjunct to the rosery. This fact suggests an instructive hint as to the direction in which valuable experiments might be made—viz., combinations of hardy teas with the finest of the hybrid perpetuals.

Were rosarians to introduce into their arrangements of sections a new one, that of HYBRID TEAS, it would obviate the difficulty of imperfect classification, and a considerable number of roses would be brought under an accurate and comprehensive head, and a skilful hybridizer would be better able to elaborate his combinations with a view to definite results. The hybrid noisette has already obtained recognition through the varieties *Louise Darzins*, *Madame Alfred de Rougemont*, and others. Of the section which should be designated Hybrid Teas, *Marechal Niel*, an improved and hardier *Cloth of Gold*, is the newest and finest example, and must be considered the most recent celebrity in the realm of roses. Cultivators are observing with watchful and anxious expectancy its behaviour during such severe weather as the winter past, and the damp and cold winds, equally trying, which usually accompany an English spring. Should it have been able to surmount such rigours, its character will be established as a rose of unique merit, marking an epoch in the rosery, indeed, and opening out a new groove for future experiments by enthusiastic practitioners of the hybridizer's art. *Devoniensis*, catalogued as a "tea," was raised many years ago by an Englishman near Plymouth, and has never been surpassed. This also is a kind of hybrid tea, raised possibly from Noisette *Lamarque* crossed with the *Yellow China*. There is a strong family resemblance in the colour of wood and leaves, and in the manner of flowering, to this rose in *Safrano*, *Madame Falcot*, *Cloth of Gold*, *Vicomtesse de Cazes*, the tenderest of roses out of doors, and lastly *Marechal Niel*.

It would be impossible in the limits of a single paper to supply an exhaustive analysis of all the roses possessing an historical interest as types and parents, or to specify the individual seedlings they have respectively produced. The leading kinds which have influenced style and improvement have been indicated, and their consideration opens up another phrase in connection with rose literature, viz., improved definitions as to the points of contour and colour.

Clapton.

W. D. PRIOR.

NOTES ON NOVELTIES OF THE SEED LISTS FOR 1867.

Aplopappus rubiginosus.—This is a showy autumn-flowering annual composite, growing about three feet high, with lanceolate incised foliage, clothed while young with a white tomentum, and producing in September large terminal corymbs of yellow Grindelia-like flower-heads, each an inch and a half across. It may be treated either as a hardy or a half hardy annual, but should be pricked out some distance apart. Native of the north-western plains of North America.

Aubrieta Græca.—We received this plant from Athens, under the above name, but it may probably be but a large-flowering variety of *A. purpurca*, with which it agrees in general habit. In size of flower and depth of colour it is, however, superior to that or any other variety we are acquainted with, and can be recommended as a most desirable plant either for beds or borders in early spring, its rich violet-purple flowers being produced for several weeks together. It received a first-class certificate in 1865.

Eriogonum umbellatum.—A very interesting perennial plant of the Polygonum family, of dwarf evergreen habit, with ovate, entire leaves, and numerous compound umbels of small primrose-coloured flowers, which retain their colour for a long time, often till the seed is fully matured. It blooms in June and July, and succeeds in any light soil. Seedlings bloom freely the second year, or occasionally, if sown very early, the first year. A native of the Rocky Mountains.

Helium Hooperii.—Most of the members of this genus being late

bloomers, the present very distinct, early-flowering species will be acceptable to the cultivators of hardy perennials. It is comparatively dwarf, with oval, lance-shaped root leaves, and rounded stems, bearing in June several large flower-heads of a uniform orange-yellow, the ray florets being somewhat drooping and persistent in character. Quite hardy in any soil. A native of Pike's Peak, in the Rocky Mountains.

Linaris Tristis.—The name of this pretty Toddflax is calculated to create an erroneous impression that its flowers are of an unpleasant, sombre hue, which is by no means the case. It was formerly cultivated, but seems to have been lost for many years. It is a dwarf, bushy, glaucous plant, clothed with linear entire foliage, every shoot terminated by a close raceme of spurred flowers each an inch in length, of a yellow or yellowish-white colour, with a conspicuous blotch of deep crimson-brown on the mouth and lower lip; in one variety the blotch is of a violet-purple, and there are several intermediate shades of colour; occasionally the flowers are pure yellow. Of the easiest cultivation in light soil, but should be planted singly, and seed-vessels should be removed to prolong its bloom. A native of south of Spain and Barbary.

Pentstemon acuminatus.—This is a pretty and distinct species, growing from 1 to 1½ feet high, with linear lanceolate radical foliage, forming a dense tuft, and long, erect, one-sided racemes of bluish-purple flowers. It is hardy in dry soils, but will need a slight protection in such as are retentive of moisture. A native of the sub-alpine districts of the Rocky Mountains.

Pentstemon glaber.—The blue-flowered section of this genus includes few more desirable species than that now offered. It is of dwarf habit, mostly quite decumbent, but occasionally more or less erect, with lanceolate, entire, smooth foliage, and terminal racemes of bright blue flowers, the throat being usually of a pinkish-lilac. It is perfectly hardy, and succeeds in any friable soil; seedlings bloom the second season, in June and July. It is a native of the plains adjacent to the Rocky Mountains. The better known *P. speciosus* is now regarded as a variety only of this plant.

Pentstemon barbatus Torreyi.—A very fine robust variety of the plant so long cultivated under the erroneous name of *Cbelone barbata*, from which it differs chiefly in its greater height and stronger growth, as well as in the general absence of the beard on the lower lip of the flower which characterises the species. Being a native of Colorado and Northern Mexico, it has a harder constitution than the typical species, and can be recommended as a very showy border perennial.

Salvia chionantha.—This plant was offered last season, but special reference to it was omitted. It is a good hardy perennial, growing about 2½ feet high, with rather small lanceolate grey foliage, and producing in July long branched panicles of large white flowers, as large as in *S. argentea*. It is a native of Lycia, whence it was sent by Boissier several years since.

Waiteia Steetziana.—This is a very pretty and distinct miniature species, well adapted for pot cultivation, though succeeding in the open ground in light soil. It grows about six inches high, producing from a tuft of linear foliage a slender stem, bearing a few scattered leaves, and a terminal corymb of sulphur-coloured flower-heads each half an inch across. The seed is very small, and should be scarcely covered with soil. A native of Swan River.

Aquilegia covrulea.—Of this beautiful plant, described in our last catalogue we have a sample of seed saved from a bed of very fine specimens, and which will doubtless give rise to seedlings possessing in perfection all the characteristics of the species.

Aquilegia vulgaris vervaeneana.—This plant was offered in our last edition, but we had no personal knowledge of its merits, and therefore deferred the recommendation that we can now honestly bestow. It proves to be a semi-double, pale purple, spurless variety of the common Columbine, with foliage handsomely mottled with yellow, and is, so far as we are aware, almost the only variegated hardy perennial which can be relied on to come true from seed. The variegation extends even to the seed-leaf.

Arundo conspicua.—A handsome New Zealand grass, resembling in habit the Pampas grass, but having the advantage of blooming at an earlier period of the summer, and therefore more desirable. We believe, too, that it produces its fine plumes while the plants are still comparatively small.

Campanula medium rosea.—This is described as being a very pretty Canterbury Bell, with pure pink-coloured flowers, and is said to come perfectly true from seed. Should this prove correct, it cannot fail to be a great acquisition.

Chrysanthemum carinatum annulatum.—A handsome addition to the varieties already in cultivation of this popular annual, having bright orange ray florets, marked at the base with a distinct scarlet ring. Fine for bouquets.

Dianthus dentosus hybridus.—Of the history of this interesting plant we know nothing, but presume it to be a hybrid of the *D. sinensis*, of which it has the habit, but is much dwarfer. It forms a close compact tuft, covered with large single or semi-double flowers, with fringed petals of a pale purple colour, marked very conspicuously at the base with very dark purple. It requires only the treatment of the Indian pink and its varieties.

Dianthus plenissimus pictus.—Another addition to the already extensive group of hybrid Dianthus, and reputed to be an acquisition of some value. It is described as a hybrid between the *D. sinensis* and the garden pink, and has large double and semi-double flowers, with serrated petals, of various shades of purple and rosy-crimson, marked with concentric rings of a deeper shade.

Eritrichium glomeratum.—This novelty is a pretty and rather singular plant of the Borage tribe, of biennial duration, from the sub-alpine slopes of the Rocky Mountains. It forms the first season a tuft of radical linear-lanceolate foliage, from which arises the following spring a stem twelve to eighteen inches high, clothed pyramidally with numerous small white flowers, bearing a general resemblance to those of a Cynoglossum. Though hardy so far as cold is concerned, it is liable to suffer from wet, and it may therefore succeed better if raised in pots for protection through the winter, the plants being turned into the open ground the following spring. It will doubtless succeed on rockwork. So far as we are aware, seeds of any of the species have never been before offered.

Euphorbia marginata.—Although the number of variegated plants is now considerable, those reproducible by seed are, so far as we are aware, limited to three or four; of these we have already noticed two, the *Aquilegia vervaeneana*, and Japanese Meize, and now introduce a third of some interest. The *Euphorbia marginata* is an annual species growing about two feet high, and remarkable for having its lanceolate foliage edged with pure white. The lowest leaves are free from variegation, but on the other hand the upper ones are almost entirely white. It requires the treatment

of half-hardy annuals, and succeeds in any light soil. A warm summer is most favourable to its full development. It is a native of the Western States of North America.

Helichrysum errera.—This comes to us from Germany with the following description, which we give without guarantee: "An extremely pretty species, with linear, terete, silver-white cottony leaves, of dwarf, compact habit of growth, and bearing handsome bright yellow blossoms. Very fine for edgings and groups. It is a half-hardy perennial, requiring only the protection of a cold frame in winter." It is probably of Australian origin.

Lilium colchicum.—To those who may not be deterred from the attempt to raise this beautiful and rare lily from seed by the somewhat prolonged trial to which their patience may be subjected, we can strongly recommend it as a most ornamental species. It grows four feet high, and yields, according to the strength of the bulb, from one to ten or more drooping flowers of a pale citron-yellow, spotted interiorly with purple, and stained externally at the base with the same colour. The flowers are highly fragrant, and in this respect are not exceeded by any species we have cultivated. It is perfectly hardy, as might be expected, being a native of Siberia, and succeeds in any ordinary garden soil. The seeds may probably vegetate slowly, and like all other flat seeds, should be sown edgewise. This plant is also met with in nurseries under the name of *L. Szowitzianum*.

Lobelia Snowflake.—We much regret having been induced to offer seed of this plant last season, and especially that it should have been described as a variety of *L. erinus*, as we were led to suppose. It proved to be but the white variety of the annual *Lobelia ramosa*, differing from it in no point, so far as we could discover. Assuredly the award of a first-class certificate to this plant by the Floral Committee of the Royal Horticultural Society is a matter requiring some explanation.

We must also apologize to our friends for having admitted the *Bisnaga major* into our last edition, as it proved to be but a wretched weed, without the smallest claim to cultivation, though sent us with a high character.

Lupinus hybridus atrococcineus.—A fine annual variety, growing 2½ to 3 feet high, with long, parti-coloured spikes of blossom, the upper portion, consisting of the unexpanded flowers, being white, and the lower of a fine crimson colour. The description is that of the raisers, as we have not yet cultivated or seen this plant.

Nemophila maculata grandiflora.—Described as having flowers as large as a crown-piece, or, in other words, two inches in diameter, and very showy and free-blooming.

Nicotiana macrophylla purpurea.—Now that fine-foliage plants are so much sought after, this new variety will doubtless be regarded with interest, as it proves to be very effective, from its vigorous growth, ample foliage, and numerous panicles of large deep purple flowers. In rich, deep soils it will attain, when planted out early, a height of 6 to 8 feet. It is offered in some lists under the name of *N. atropurpurea grandiflora*, but we believe the above to be its correct designation.

Scabiosa nana flore pleno.—This is described as a valuable improvement on the dwarf Scabious hitherto cultivated—the flower-heads resembling those of the pompone Chrysanthemum, almost globular, and in habit much dwarfer and compact. The colours are described as being very varied.

Schizanthus ocellatus atropureus.—The singular form of the flower, and its usually handsome markings, have invested the plants of this genus with interest from the earliest period of their introduction. The present fine variety is stated to be a seedling from the *S. grandiflorus ocellatus*, from which it differs in having flowers of a rich crimson-purple, with very dark centre. A hardy annual.

Stipa elegantissima.—Among the ornamental grasses, none are characterised by greater elegance than the different species of Feather grass or Stipa, and of these the present plant, a very recent introduction, is, we think, one of the most graceful. It is of Australian origin, and is therefore rather less hardy than *pennata* and some others, but succeeds well with us in a light sandy soil. It grows about two and a half feet high, and yields long panicles, very much branched, each branchlet bearing a seed terminated by the long awn peculiar to the genus. It is of perennial duration, and does not flower till the second season.

Tropaeolum Tom Thumb (new rose).—Identical in habit with the so called Scarlet Tom Thumb Nasturtium; it differs from it in the colour of its flowers, which are represented to be of a rose colour, or the exact counterpart of Trentham Rose Pelargonium.

Viscaria cardinalis.—This is represented to be a very fine variety, with large flowers of a bright magenta-crimson; we presume that it is a variety of *V. ocellata*, but have no precise information on this point.

Willowia graniflora gloxinoides.—A pretty novelty, differing from the type in its flowers having a margin of a delicate light blue, and the throat of a pure white. If constant, this must prove an acquisition.

Xeranthemum annuum corypholoides.—This is described as a really striking variety of this favourite everlasting, the flower-heads being very double, and spotted and streaked with rose, red, crimson, and purple, on a blush-coloured ground. It will prove a valuable acquisition for the borders, as well as for dried bouquets. In habit it is more compact than the older varieties, and it is quite constant in its character.

Zea Japonica variegata.—As most of the variegated plants now so much employed for gardening purposes require to be increased by cuttings, any annual with variegated foliage reproducing itself faithfully by seed could hardly fail to be popular, even were it less ornamental than this new dwarf maize. It is described as attaining a height of six feet, but our own plant did not at all exceed four feet, owing perhaps to the inclement summer. The foliage is broadly ribboned with alternate stripes of white and green, and near the summit the white predominates largely, as well as in the foliage of the secondary shoots which surround the principal stem. Whether planted singly or in groups, it produces a highly ornamental effect, and its shoots will be found very useful for cutting. A light rich soil is best suited to its requirements.—W. THOMPSON'S (*Ipswich*), *Descriptive Catalogue of Flower Seeds*.

FIVE HUNDRED VARIETIES OF FRUITS arranged so as to indicate which are the best for orchards, gardens, for forcing, for market, for the dessert, the kitchen, &c. From this list any one, or any six or twelve, of the best in each class may be selected. Also, Selections of Florists' Flowers, Decorative Plants, &c., adapted equally for trade and amateur cultivators, and all founded on frequent and careful observation. In the GARDEN ORACLE for 1867, edited by SHIRLEY HEBBERD, Esq.

THE GLOXINIA.

In my paper on the Achimenes I directed the attention of my readers to the growth of this flower, both for home use and for exhibition. I shall now treat of the Gloxinia with the same ends in view, for it is in every way adapted for the same purposes as the Achimenes; indeed, it may be considered its proper companion as a decorative plant, so well does it flourish when submitted to the same treatment.

The Gloxinia may perhaps be entitled to the precedence in respect to the seasons of flowering. I have known them by peculiar management to produce two crops of flowers in the same year, by getting them to complete the first blooming early in the summer, and then, after allowing them a brief season of rest, to slowly excite them into growth again, not disturbing the roots in any other way but by giving them a slight top-dressing of fresh soil.

It may be that some sorts will not so readily yield to the above treatment; if so, do not push them, but put them aside, so to remain in their dormant state till required in the regular season. But should you succeed with the second season of flowering within the same year, it will greatly enhance the floral beauties of the stove during the late months of the autumn.

With this class of plants, as with the Achimenes, the promoters of our great metropolitan exhibitions have overlooked their attractions as subjects suitable for competition. Since the decline of some two or three of our principal local floricultural exhibitions in the metropolis, it is seldom now within its radius that we come in contact with large specimens, either in private or public gardens, such as we were accustomed to behold in the palmy days of the Stamford Hill Horticultural Society, as grown by Messrs. Chitty, Holmes, Taylor, Oubridge, Wookey, and others whose names I have forgotten. It was then a glorious floral treat to survey a side table extending some forty or fifty feet occupied only by this class of plants. Not only were they clothed with plenty of flowers, but combined with it most luxurious foliage. The sorts at one period were mostly the drooping varieties, but towards the latter years of the society's existence the erect kinds became more general in cultivation; and who could fail to admire them? for among them prevail some of the most charming and pleasing colours. I can at this moment recall to my memory a basket of seedlings as exhibited a few years ago by Mr. Fraser, of the Lea Bridge Road Nursery. I could not express my feelings while gazing on them, so enraptured was I with the rich and varied shades of colour there presented.

As cut flowers for furnishing vases or baskets for indoor decoration, they are admirably adapted, as their soft but rich hues blend exceedingly well with other more dazzling colours.

We will now proceed to say something about their general culture. Like the Achimenes, they thrive very rapidly in a very warm humid atmosphere to which is added bottom-heat. As they advance in growth, afford them plenty of room for the expansion of their foliage; with this, as with other plants, crowding will be sure to frustrate your efforts. Some varieties will produce long shoots, while, on the contrary, others are more compact and dwarf in their habits. But the former would be benefited by being stopped according to their strength and the number of shoots they may make. Of course the result of stopping will be an increase of side-shoots. But no instruction of mine can make you so thoroughly acquainted with their requirements as your own individual study of their respective habits.

In selecting bulbs for potting, my preference would be those two years old, as experience has proved to me that they make the best and most thrifty specimens, compared with younger or older plants. My practice is, after turning them out of their past season's flowering pots, and shaking the soil from them, to place them in single layers in a shallow box, only introducing sufficient sand or light sandy soil as will cover the fibrous portion of the bulb. There they remain in a shady but warm part of the stove till they have pushed their shoots an inch or so. By this method I am enabled to decide as to what size pot they may require—the number of shoots emitted being my guide, instead of the size of the bulb; and why? because those who trust to the latter are sometimes disappointed. The bulb may have degenerated in quality during its season of rest, although previously in an excellent state of preservation.

With all healthy bulbs that have exceeded two years' growth, I adopt the one-shift system—that is, put them in their intended flowering pots at once; to younger bulbs I give repeated shifts, commencing with a pot sufficiently large to contain the bulb. In potting, do not bury them too deep in the soil, but allow the crown to be somewhat elevated above its surface, so that no water may effect a lodgment in it. By all means afford them plenty of drainage when potting, for although they require a liberal supply of water when growing freely, yet they will soon show signs for the worse in a stagnated soil.

They will grow in almost any soil which partakes of a sandy nature. Some use equal portions of loam and peat with silver-sand.

If you have the means of affording them plenty of bottom-heat, then add more loam than peat; but on the other hand, if you cannot command as much heat as you wish for them, use more peat than loam: in fact, in such a case let your soil be of a light sandy nature. The reason why I recommend peat in the absence of sufficient bottom-heat is that it is not so liable to become sodden and cold, it being a better conductor of heat of the two soils, and of a dryer nature than loam.

In the absence of any other means, I have grown them in brick pits heated by the aid of hot manure linings. The same instructions as to giving air, "shading," &c., apply to them as recommended to be adopted in the culture of the Achimenes. Any neglect of the rules advised would inflict the same consequences, viz., disfigurement of the foliage, a weak habit, and an unsatisfactory bloom. When they begin to flower, they will need a drier atmosphere. If your pots are placed over flues or hot-water pipes, you must be watchful that the foliage does not become injured by the hot steam; and if your houses are heated in the old-fashioned style by brick flues, take care there are no cracks by which the sulphurous fumes from the furnace can escape, as in the course of my practice I have been a sufferer from such a misfortune, having had the foliage partially destroyed when they have been in the best possible state of growth. Before you close the pit or house on a fine afternoon, give them a gentle syringing. On fine mornings give air early, or the sun's rays will sadly spot them before the foliage is dry. The constant syringing on warm evenings, and the keeping the house moist, will act as a preventive against the attacks of thrip; in fact, a slight fumigating now and then will benefit them by checking the growth of insects of whatever kind might be lurking about. I have seen a collection of plants grown to an excellent state of perfection, when all of a sudden, owing to their being changed to a very dry atmosphere just at the period they were about to flower, thrip has attacked them, spreading with such rapidity as to effectually nullify the anxious labour of many months, so that the successful blooming of the plants was hopeless for that season.

When the plants have ceased to flower, I gradually dry them, when they are stowed away in a temperature of not less than from 45 to 50 degrees, being placed in such a position that water will not reach the bulbs.

JOHN F. M'ELROY.

CAMELLIA CULTURE.—No. I.

The Camellia is so universally admired by all classes of cultivators, that I am sure it will be time well spent if I devote a portion of the space allowed me here to set forth some of the chief points it is necessary to observe to secure success in its cultivation. In treating of a subject that more or less concerns nearly every reader of these pages, there is a sort of certainty that the writer's efforts to handle it practically will be appreciated, and I am convinced it will be so by all true admirers of this noble flower. With just this sort of confidence I set myself to this task, only hoping that it may be useful when completed.

For our first consideration we cannot do better than make a selection of useful sorts. This done, we can then go into the details of their culture, only making such remarks as we go on as may seem necessary respecting the peculiarities requisite in the culture of any special variety.

AS WHITE CAMELLIAS are very general favourites, I will place them first on the list, and perhaps the best in this section for general purposes is *Cup of Beauty*. It is of excellent habit, being close and compact, and an abundant bloomer. In fact, for ordinary conservatory decoration, it is the best white we possess, although we have many more of the same colour; and although it does not approach the standard of excellence in the way of shape and substance of petals that characterises the true florists' flower, it is nevertheless a most useful variety; it is very pure in colour, and an excellent autumn bloomer. But in this respect it wants a little management, according to the time it is required to flower, as if it is encouraged to make its new growth very early in the year, it will flower through the months of September and October following, so that if wanted to flower later, or rather to be at its best later, it should not be encouraged to make its new wood until March. At the time of writing (January 31st), we have a plant in the conservatory, with eight or nine expanded blooms upon it, that has been gay with flowers since the first week in September of last year, and it is only occupying an 11-inch pot. Then there is the *Old Double White*, which is still a deserving favourite with the majority of cultivators—more especially those who require a quantity of cut flowers, or where an individual plant is wanted to make a lasting and telling object. Its habit, when properly cared for, is all that can be desired, and the shape and substance of its flowers is not to be despised. It requires liberal culture in the way of rich open soil and a moderate degree of pot-room; with this treatment it does not require the aid of stimulants to excite it into growth, and they should never be resorted to all the time it is practicable to give it more pot-room. If this cannot be done, then

a few doses of weak guano-water may be applied when it is making its growth. Of other white-flowering kinds, there are many very chaste and beautiful varieties, really models of perfection, in the contemplation of which the stern advocates for form and substance can feast their delighted eyes. But I must not appear bigoted in this matter, for without reluctance I admit that the rules which the true florist sets up to guide him in his estimation of what a true-formed flower should be, are excellent, and indeed essential, for without some such standard to guide us as to which is and which is not a correct-formed flower, the confusion would be so great that only the deeply initiated would have any idea of the real merits of half the flowers we grow.

The most meritorious as viewed from the florist's point of view, is *Feastii* and *Fimbriata*. The former of these is perhaps the largest and boldest of the whole batch of whites. It has an excellent habit, and succeeds well under ordinary careful management, while *Fimbriata* is a well-known and an accepted favourite, especially with the fair sex. This variety will not bear rough usage with impunity, but when under skilful hands it seldom fails to produce an abundance of its fine fimbriated flowers. Should the reader require any others of this colour, then I would add to the list *Miss Percival* and *Noblissima*. This last is a very useful early-flowering kind, and will often produce a good display of flowers under disadvantageous circumstances.

I shall now name a few of the RED and CRIMSON section, and as one of the best I shall place first *Mathotiana*, sometimes seen under the name of *Matholiana*. This, when at its best, is a bright crimson, of fine form, rather loose in habit, and a spare bloomer when not properly cared for. But a few of its flowers, when well expanded, are so conspicuous that this very excellent quality is a good set-off against its shyness in blooming. It requires an average temperature of 50° to induce it to open well and with good form. *Bothwelliana* is a first-rate late-flowering variety, and of a colour conspicuous among camellias, being considerably darker than many others of the same strain. The number of petals and the general outline of the flower is so good that I may fearlessly class it as a florists' flower of the first order. It has no particular peculiarities in culture to be observed, as with me it has done exceedingly well under the same treatment as the general collection has received, and which comprises a good number of the best in cultivation. Another very excellent one is *Imbricata*. This is occasionally mottled with white, but a fine bold flower of good substance and form, and altogether a very desirable acquisition to any good collection however small. *Archduchess Augusta* is a deep crimson, shaded and veined with a purplish hue. This is perhaps the most distinct of any in this shade of colour. I have lately much regretted I had not this variety to compare with some others which we have nearly like it in habit and the form of its flowers. *Leeana*, a rich scarlet-crimson, with finely cupped petals, is too well known to need any description from my pen. But I may venture to say that it is a deserving useful variety, more especially where superior cultivation is not carried out. *Speciosa* is an old variety, very large and showy, more suitable to make an effect in a show house than for individual beauty. A far more desirable kind is *Scipioni Africano*. This produces a superb scarlet-crimson flower, shaded with violet, and sometimes a few of the petals are streaked with white finely imbricated, and of fair average value in the form of the flower.

I shall in the following list include all that it is necessary for me to particularize, including BLUSH, CARMINE, PINK, and the MOTTLED or STRIPED VARIETIES, as there are so many kinds included in the above different shades of colour, that this list of varieties would be extended to an unprofitable length if I were to devote separate heads to each; and as a very worthy pioneer I shall select the *Queen of England* as my first subject. In this place it is a delicate rose-coloured flower, with white stripes in the centre of each petal, and of exquisite form, but not of a very robust constitution. *Princess Maria* is a beautiful soft rose edged with white. *Rubens* is of the same colour, but larger, more imbricated, and of better form than the last-named. *Wildierii* is a well-known kind, useful for all the purposes for which camellias are cultivated; of fine form, with a well-deserved character of being a free bloomer. The *Marchioness of Exeter* is a thin flower, but of exquisite form, and the habit of the plant close and compact. It requires plenty of pot-room to induce it to flower freely, and when the flowers are expanded should stand in the coldest part of the house, otherwise it sheds its flowers too freely. *Elegans* is another old and useful kind where a gorgeous display is wanted, but it is not to be recommended where individual beauty would be criticised severely. It is a vigorous grower, and the most abundant bloomer that I know under adverse circumstances. Of the more beautiful striped rose flowers, I certainly prefer *Tuccaria*, *Valtevarado*, *Nassimiana*, and *Lady Taunton*. These four will not disappoint the most ardent of cultivators, provided he treats them liberally, but they all require careful attention, and should be encouraged to

make their new growth before Midsummer, that they may have time to properly ripen their wood and swell their buds before winter. *Alexina* is rather a scarce blush colour, very beautifully striped with rose. *Fanny Bolis* is in the same strain of colour, sometimes very handsomely mottled, but a much fuller and bolder flower, and altogether very perfect in form; this is a newish variety. *Princess Frederick William* is another new kind in the way of a blush-white; it is a strikingly fine-formed flower, but scarce and dear. *Unica* is a delicate blush, very nicely imbricated, but not so robust with me as I should like it. Of striped flowers, perhaps the best is *Countess of Derby*. I have only seen this variety once; it was then very distinct, and a noble flower. Then there is the *Countess of Ellesmere* and the *Duchess of Northumberland*, both good and useful varieties; to these the cultivator may add, without fear of disappointment, *Magdalena*, *Maria Theresa*, *Prince Albert*, *Duchess of Orleans*, and *Mrs. Wilder*. This last is of excellent habit and constitution, and deserving of a place in every collection. With this one I shall close the list, as sufficient varieties have been named to suit the convenience of most private cultivators, and to add more would be to cause a confusion in the minds of those who might wish to choose from it.

It may be well to remark, for the information of amateur readers, that I have distinctly stated in the foregoing list sufficient for them to judge of the excellences of any one variety, as all I have named are good and worthy of general cultivation; and I have, I hope, made it sufficiently intelligible whether they are to be appreciated according to the standard of the florist or not, because tastes differ so much in this respect that where one individual admires the correct outline of the florists' flower, another prefers the bold characters of the other section, and rather prefers them for their adaptability for making a display than for the individual beauty they possess. But as regards the florists' flowers, there can be but one opinion, that they are very chaste and symmetrical, worthy alike for their beautiful outlines and generally correct markings.

J. C. CLARKE.

MY ORCHID HOUSE.—No. XI.

THE STANHOPEA.

Though it is many years ago since I saw a plant of this genus pushing its very lovely blossoms through the openings in the bottom of the basket in which it was growing, I can still recall the feelings of amazement, mingled with no small amount of pleasure, which I experienced at beholding for the first time what I then supposed to be a wonderful phenomenon or freak of nature. Now, although a greater practical knowledge of plants and a much wider range of observation and acquaintance with the many and varied personages of the vegetable kingdom has somewhat rudely dispelled the illusion of its being the most wonderful plant in existence, I still retain the opinion that (putting aside the peculiar and curious manner in which the flowers of this genus are produced) the Stanhopea stands second to but very few orchids, if we properly balance and fairly compare its different qualifications. Amongst them I may enumerate cheapness in first cost, easy culture, and requiring but very little outlay to keep up a suitable temperature; and the shape, texture, and the exquisitely beautiful markings of the blossoms, render them quite matchless in their way. Like the Lycaste, this plant requires the assistance of fire-heat very sparingly in favourable seasons, after it has once fairly started into growth in the spring. It will not be necessary for me to occupy space in lengthened remarks on temperature for the Stanhopea, for the one recommended for the Lycaste will be perfectly suitable. The extraordinary manner of flowering of this splendid plant, the flowers being sent downwards, renders it more suitable for basket culture than for growing in pots. The open-work of the basket affords every facility for the flower-stalk to push through the soil, and out into the air, without suffering any impediment or obstruction in its downward progress. If grown in pots, the plants will necessarily be required to be potted so high, to allow a free development of the flowers, as to give one the very uncomfortable impression of expecting to see it topple over every moment—a feeling that is not at all desirable at any time. I detest anything that makes me feel or fancy that the object I am admiring (whether belonging to the floral world or not), may at any moment be dashed to the ground, and my enjoyment be suddenly brought to an end. Some pieces of crocks sufficiently large to prevent them falling through should be spread over the bottom of the basket, which will serve the purpose of drainage, and also keep the material in which the plants are planted in its proper place. The plant in question will grow in peat or sphagnum. I prefer the latter; it looks best if the base of the bulbs are elevated an inch or so above the level of the basket.

I prefer baskets made of wood a long way before wire ones, whether iron or copper is used in their manufacture. The wooden ones have a decidedly more natural appearance, and at the same

time afford a certain amount of nourishment to the orchidaceous plants growing in them; at all events, the tenacious manure in which the roots of orchids in general, and the Stanhopea in particular, adhere to the pieces of wood composing the basket, demonstrates pretty clearly that if they do not actually derive nourishment from it, that the wood is much more favourable to the development of the roots than either iron, copper, or any other metal suitable for basket-making. Besides, the wood baskets can be easily and quickly made at home without any expense. Branches of either the common maple or hazel are best for the purpose. I have a decided preference for the former with the bark left on; it has much the prettiest appearance about it. I have made numbers of larch; they look very well, but are scarcely so durable as the other woods. I will describe as briefly and simply as I can my way of making them. I don't suppose that it differs materially from the ordinary basket which is generally used in orchid houses, but the description will be useful to any one not acquainted with the manner of making them. Supposing I want to make a basket twelve inches square, which is a very useful and convenient size for general purposes, I take rods of the wood selected for the purpose, and which should average an inch in diameter, and cut them into lengths of twelve inches each, and bore a hole sufficiently large to allow stout copper wire to pass through an inch from each end of them. I then lay four pieces parallel to each other; the two outside ones must not be more than eleven inches from each other, and a piece of copper wire eighteen inches long run through the holes already bored in them, across the sides of the four. Two more pieces must be laid and threaded on the wire, and nailed to the four pieces across the ends of these two; a couple more must be put, threading them on the wire as before, and nailing them to the two rods which form the second layer, and so continue till the basket is finished, putting each pair of rods in opposite directions, running the wire through them, and nailing them so as to keep the basket firm. A basket four or five inches deep is enough for any of the Stanhopeas. When the last layer is put on, bring the ends of wire together, and fasten them to hang the basket up by. Some people merely put the wire through the rods without nailing, but they slip about, and do not keep their proper place at all nicely. Others, on the other hand, use nails only, and fasten the wire to the top of the basket; but this is worse than the other, for when the wood begins to decay the nails are liable to draw out, or else the pieces will give way that the wire is fastened to. For smaller baskets the wood will not be required to be of so large a diameter, whilst for larger sized ones it must of course be thicker than I have recommended for the twelve-inch basket. The Stanhopeas, like most orchids, are propagated by divisions. *S. grandiflora* and its varieties bloom in June, *S. insignis* and the varieties belonging to it in September, *S. oculata* and varieties of it the same time as the first-mentioned, whilst *S. tigrina* blooms a month later. I have not thought it necessary to enumerate a long list; these four are really good, and can be obtained for a very trifling sum.

GEORGE GORDON.

THE HOLLYHOCK AS AN ANNUAL.

Such quick methods of production are followed now-a-days, that none of our readers will be surprised to hear that Hollyhocks may be raised from seed and flowered the same season, and that there is no real necessity to treat it as a biennial as our grandfathers did, for it is an annual as truly as Virginian Stock or Clarkia pulchella. Perhaps I should not have commenced with this remark except that I remember learning from the lively pages of the GARDENER'S MAGAZINE that a very short time since a gabbling goose who pretends to speak authoritatively, but who really knows very little, had publicly disputed the assertion of a cultivator that he commonly flowered hollyhocks the same season that they were raised from seed. There is, in fact, no mystery in the matter. Any one who will give me within a fortnight of this time a packet of seed and a challenge worth heeding shall see the plants in bloom from that seed before 1867 is out; aye, and before the good weather in which hollyhocks can flower well, and lovers of gardens can enjoy them, is past. And the matter is of great importance, for this noble plant is well adapted to be largely employed for effect, in which case individual perfection is of less consequence than colour, dignity, and picturesqueness. The amateur who requires only a few dozen, and who rejoices in growing the most perfect flowers he can obtain, will of course purchase named sorts, and continually add from the new varieties such as are adapted for his collection. But our parks, great gardens, cemeteries, and other places where bold effects are required, may be as well stocked by raising seedlings as by the cultivation of named kinds; and I hope that, as the taste for something better than the daubs of colour that fashion demands as accompaniments to walks and drives, and that collectively obtain the designation of "Bedding"—I hope that as these daubs give place to noble forms, to refined combinations, and to the production of grand pictures, the Hollyhock will take its proper place, and be as much esteemed by decorators of gardens as by painters of landscapes, who never fail to introduce it

when they depict garden scenes. A weather-stained vase and a group of hollyhocks were favourite embellishments of a picture in the hands of Sir Joshua Reynolds, and I learnt not long since from our able Editor's pen that the poet Wordsworth delighted in avenues of hollyhocks in his garden at Rydal. Perhaps Mr. Beningfield took the hint therefrom; at all events those who wish to see avenues of hollyhocks only need go to Broxbourne in the proper season, and if such a sight is new to them, I can say that novelty will be accompanied with surprise, delight, and every material for a pleasant memory.

When I first began to treat the hollyhock as an annual, I felt it necessary to push them on early, but I soon discovered that it was possible to be *too* early, and now they come into the regular routine of spring-work, and the seed is sown any time between the 1st of February and the 1st of March. I am quite satisfied that in the south of England the seed may be sown throughout the month of March, and the plants will, with proper management, be quite forward enough to plant out in May, and will bloom well in August and September. It must be understood, however, that this quick growing must be *well done*—there must be no shilly-shally, and no starving. Sow the seed in shallow pans filled with rich light earth, in a rather lumpy state. If a recipe be wanted, say, loam two-thirds, and quite rotten manure one-third, with some coarse grit added. Break this well, but do not sift it. I like to see it in lumps as large as hazel-nuts, and the whole soil granular, so as to look *as if it wanted sifting*. Sow thin, and cover with only as much of the finer part of the soil as will just hide the seeds. Lay over the pans some tiles or boards, or even sheets of paper, and put them in a heat of 60°. If properly done, there will be no need for water till the plants are pushing freely. There is no harm in giving a good watering when the seeds are sown before sprinkling a bit of fine stuff over them, for if put in heat directly, a rather wet state does them no harm, and they will be very nearly dry by the time they start freely. The quick practice makes work almost directly. Put them full in the light as soon as the seed-leaves appear; give as little water as possible; and to ascertain if they are moist enough, keep a bit of stick (clean deal) thrust into the soil of every pan, so that by drawing this out occasionally you may learn exactly what is the degree of moisture underneath.

Prepare for potting a good heap of such compost as the seeds are in, with plenty of grit mingled with it. Rotted hops make a nice admixture if you have such stuff, but there is nothing like having a predominance of good loam from the first, as in the earliest stages of its life the plant is collecting the energies that are afterwards to be expended in the production of flowers. This compost should be placed in the propagating house, or any other warm place, for a day before it is wanted. I prefer to pot them singly in thumb-pots as soon as the rough leaves appear, as at that stage they do not feel the least check in the operation, the seed-leaves having so much power of sustaining the plant. Lift them out with a bit of stick; pot them like lightning, giving each a tap as finished; and as they are potted plunge them all in a bed of warm hops, or place them on a moist bottom in a heat of 65 to 70°, and without any shading. My little house has a rough wooden table sprinkled over with about

two inches of cocca-nut fibre, and on this all pots containing newly struck cuttings, &c., &c., are placed, and it is astonishing how the moisture below promotes their health and strength. The pots will be full of roots in no time. Shift them into 60-size, and again place them on a moist bottom in a temperature of 60 to 70°, but in the course of a week remove them to a cooler air, and begin by slow degrees to harden them. The season will be now so far advanced that a house not heated will do for them, and at first they must not be ventilated for a few days. But when the sun shines bright, plenty of air may be given after two or three days have elapsed. They will soon be thrifty plants, the leaves

spreading over the pots, looking vividly green, and growing rapidly. When the pots are filled with roots, shift them to 48-size. In all these shiftings, one crock in a pot is enough, and that need not be removed in turning out. I never use crocks at all for such work as this; it seems a waste of time; but an amateur not used to the regular work of the propagating house had best put a nice hollow crock in each pot to make sure. There is very little more to be done, but as they will probably be in the way from the amount of room they consume, they may now go to cold frames, pits, or even to a dry sheltered border where a mat can be put over them in case of frost.

Seedling Hollyhock, average quality, light.

The planting-out must be as liberal as the growing in pots. Nothing but thin spikes and open blossoms can be expected if they are turned out on poor soil, or left to fight out their existence on soil half dug and without a drop of water to help them during drought. Let the piece be deeply dug and liberally manured some weeks before planting out. The middle of May is early enough, except in peculiarly favoured localities, or in very forward seasons. It must be remembered that having been pushed on fast, they will not bear much hard usage, and therefore it is not safe to plant them out till spring frosts are over. Plant them in regular rows,

three feet apart every way; close them in neatly. If planted in showery weather, they will probably take care of themselves, and grow away gloriously from the first; but in the event of dry weather, give each plant a little water every few days till their free growth proves that they have "taken hold" of the ground, after which they will require very little care.

When planted in a large piece or in avenue rows, the best way to hold them up against wind is to drive down some stout oak posts at each end of a row, and carry two stout galvanized wires from post to post, to which the stems are to be tied. This is an *invisible* mode of supporting, very effectual, and far less trouble than the ordinary mode of putting a stake to every plant. It is a rule with me to plant lettuces all over the piece a week or two before putting out my seedlings. The vermin assemble in and about the

Seedling Hollyhock, average quality, dark.

lettuce, and never touch the hollyhocks while there is a lettuce-leaf left; and the lettuces serve as effectual traps. In the latter part of the season, the earwigs become very troublesome, for they lodge in the joints, and it is difficult to deal with them. There is no plan so good as trapping, for which directions have been given so often that I will not add to the length of this paper by any further remarks on the subject.

As to seed, the hollyhock has this excellent quality, that nine-tenths of all seedlings from good strains are worthy of admiration. Here and there open-eyed, pockety, or even single flowers occur.

But a very large proportion come in the same colours and (within a certain mark) of the same form as their parents. The cultivator of seedlings for effect may therefore select such colours as he wishes to have, and may plant out according to any system which taste may dictate, with almost as much certainty as if the plants were grown from cuttings. The leading houses offer seed in packets named from the varieties they are taken from, and as a rule the named seeds are of the best quality and saved with every proper care. I am bound to say, however, that I have always planted mine indiscriminately, having in view to select a few plants from the seed-bed for naming and propagating, and moreover I never grow any but seed of my own saving. In respect of the trade seeds, therefore, though I speak from actual knowledge, I do not speak from personal experience. Avoid cheap seed, and if possible obtain it from some house that has a first-class reputation.

Last summer I made several sketches of flowers and spikes from plants raised from seed sown the second week in February. From these I have selected two, which I send; they represent neither the best nor the worst, but what I consider a fair average of the quality from good seed. The light flower has rather too large a guard, the dark flower is scarcely smooth enough in the edge, but both are good. At a future time I will send a sketch of what I consider a perfect hollyhock should be. E. H.

Calendar.

WORK FOR WEEK COMMENCING FEBRUARY 16.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN crops to be cleared off as fast as possible, and the plots ridged up, to be well aired before being appropriated to summer crops. Sow main crops of peas and beans, earth up any that are now out of the ground, and if any fear of vermin sprinkle with wood ashes. We believe the common slug has more to answer for as to the destruction of early rows of peas than any other depredator.

CELERY large enough to be pricked out to be removed forthwith to a sweet hotbed. Sow again for the main crop.

CUCUMBERS for ridge culture to be sown now, or within a week or so of this date. Sow also for frame culture to succeed plants now bearing. We prefer sowing in 60-size pots, two seeds in a pot, the strongest plant in each to be kept, and the roots never to be damaged by shifting, so as to have them strong and short for turning out.

POTATOES may be planted for main crops, but the operation must depend very much on the weather. Better delay a week or a month than plant when the ground is wet. Put all seed potatoes in full daylight in shallow baskets, in thin layers on dry hay or straw. By keeping the shoots short and plump, there is less likelihood of disease, and the vigour of the sets is not impaired.

ARTICHOKES will soon require to be dressed for the spring, but the time chosen for it must be regulated by the weather. If frost prevails, leave them alone for the present; but if mild open weather, remove the protecting material, fork over the ground between the rows, and give a good dressing of rotten manure and wood ashes.

CAULIFLOWERS coming up thick in pans and boxes to have a little dry earth or wood ashes strewed amongst them, as oftentimes advised by Mr. Clarke in his practical papers on the management of seedlings.

ONIONS required to be very large may now be provided with a deep, well-manured bed in a rather dry position. Transplant into this bed from the seed-bed of autumn-sown stock, putting the bulbs nine inches apart; if only serviceable bulbs be required, put them six inches apart. After planting, strew wood ashes or fine siftings of charred rubbish over the bed.

PARSNIPS to be sown now on deep, well-stirred soil. If heavily manured last year, all the better, but on poor soils they give a good return. In case of requiring large, handsome roots, trench deep, and lay manure at the bottom of the trench. When the ground is ready, take a stout iron bar or iron-shod oak-stave, and make holes fifteen inches deep, nine inches apart, in rows fifteen inches asunder. Fill these holes with sand, or any fine soil, sow a pinch of seed over each hole, and cover lightly. When the plants appear, thin them to two or three in each patch, and as soon as they begin to make rough leaves freely remove all but the strongest one in each patch. By this plan they will grow to a great size, and as straight and tapering as if turned out by a lathe. The parsnip always pays for the ground it occupies, for if sown on poor soil it gives a good return of useful roots, though as there is great waste when these are forked or cankered, good cultivation is to be preferred, both because more creditable and more profitable.

PEAS AND BEANS sown on strips of turf, or otherwise intended for planting out, should now be hardened by exposing them as much as possible to the open air, but it must be done without causing any serious check, and if the nights are frosty they must be covered up early. When they have been exposed for eight or ten days, they may be planted in rows to take their chance. Beans are growing fast, and require earth to be drawn to their stems. This operation will destroy the weeds, which are also coming up rather thick.

Flower Garden.

TENDER ANNUALS for specimens and bedding out to be sown now include Balsams, Cockscombs, Globe Amaranthus, Portulacas, Schizanthuses, Phloxes (don't forget Phlox Drummondii Radowitzi), Brachycomas, Stocks, Tropaeolums, Colerases, Lophospermums, and Aconitum. It is too early yet for Asters. First-class annuals should be grown with care, the plants to be pricked out early and stopped; if they once get drawn, they never bloom satisfactorily, or show their full capabilities.

HARDY ANNUALS.—Generally speaking, the greater the variety used in a garden, the less pleasing will be their effect. Half a dozen well-selected sorts will produce a richer and more harmonious, as well as more manageable picture. We have seen on a broad herbaceous border, alternate clumps of Escholtzia crocea and Clarkia pulchella—the clumps two feet across and four feet apart—and while the bloom lasted, and the flowers were fresh, nothing

could be more effective: the contrasts were rich and satisfactory, and the broad masses of repeated colour gave a distinct character to what was otherwise a mixed collection. When the plants in these clumps began to get seedy, they were at once cleared off the ground, and replaced with purple verbenas and dwarf calceolarias in clumps, and the effect was again charming. The best of all ways to use annuals is in large masses of distinct colours, to have no half-tints or mixtures, and to have very few kinds. If they do not last the season out, it is an easy matter to remove them, and plant again, because during May and June almost any kind of bedding plants may be propagated in quantity with very little trouble, a few hand-lights or a frame being quite sufficient. But to follow annuals, the best things are annuals again. By the time that Virginian stock, nemophila, and other early-blooming kinds are over, balsams, and asters, and stocks may be raised in quantities to plant out in their places, and these will last in bloom till frost makes an end of them. But in whatever way they may be used, we recommend those who merely wish for gay colours, and have no idea of making collections of plants for botanical purposes, to grow very few, and let those few be the best. The following is a selection arranged in colours; there is not one entered but is worth a place in a duke's garden, and they are all so cheap that the poorest cottager may by their means have a grand flower-show entirely of his own.

White.—White Candytuft: this is truly splendid in large masses; thin to four inches apart. Nemophila maculata: this is a delicate-looking thing, not very showy, but quite a gem in its way. Phlox Drummondii alba: this is to be sown on a hotbed, or in a pan in a warm window. Portulacca alba: a dwarf succulent; sow in a mixture of loam, sand, and old mortar, equal parts; place in a frame or window, and plant out on dry sunny banks. Saponaria calabrica alba: a neat dwarf, profuse-flowering annual, very hardy; and grows in any soil. Cynoglossum linifolium (Venus's navel-wort): an old-fashioned and silvery-leaved white-flowered annual; grows in any soil or situation, three to four inches apart. Virginian Stock: not much prized, but very beautiful while it lasts, and useful to occupy places that are to be filled with later-blooming plants. Pink and Rose.—Saponaria calabrica: the same as above described, but with rosy-pink flowers. Silene armeria: true magenta colour, the plant very neat, and the flowers produced abundantly. Centranthus maerosiphon: thin to five or six inches apart. Clarkia rosea. Eueharidium grandiflorum: this will bloom late unless sown in heat. Gillia tricolor rosea: dwarf and pretty. Godetia rosea alba; grows eighteen inches high, and should be thinned to six inches apart. Rosy branching Larkspur: grows two feet high; thin to six inches apart. Oxalis rosea: a lovely annual for pots or borders; the flowers close during rain. Viscaria oculata: grows a foot high, and must be thinned to seven or eight inches apart. Crimson and Purple.—Iberis Kermesina: this is a splendid crimson candytuft; there is also a purple candytuft. When obtained true, these are the most uniform and effective hardy annuals ever grown. Sown early in a rich soil, and thinned in good time to six inches apart, they make splendid beds, and may be removed in good time to follow with fuchsias or variegated geraniums from spring cuttings. Very few seedsmen can supply these new and beautiful varieties, and unless the purchaser is careful in obtaining them, the result may be washy lilac flowers instead of rich masses of glowing colour. Clarkia pulchella: thin to six inches apart when in the seed-bed. Indian Pink. This needs a rich soil and sunny position. Blue.—Nemophila insignis: blooms early, and is soon over. Venus's Looking-glass (Campanula speculum): this is equal in its way to the purple and crimson candytufts, and its dense masses of purple blue flowers are unequalled. Ipomea tricolor cœrulea: this always turns its flowers to the sun, and has the best effect in beds and borders on the north sides of windows. If planted to the south of windows, the flowers will be almost hidden by the leaves. Kaulfussia amelloides: similar in growth to Nemophila, and a truly beautiful annual. Lupinus angustifolia: there are several fine lupins; if you grow all you can get, there will be no waste of ground, they are so beautiful. Yellow.—Euthamia Veitchii: dwarf and neat. Leptosiphon aureus: a most beautiful dwarf free-blooming plant. Escholtzia crocea; the best for clumps. Escholtzia tenuifolia: very beautiful where a miniature plant is required; the primrose blossoms are very pretty. Lupinus luteus: pretty and sweet-scented, but of very brief duration. Salpiglossis sulphurea splendens. For MIXED BORDERS, annuals of taller growth may be used, such as peony-flowered Poppy, Calliopsis, Lupinus mutabilis, African Marigold, Chrysanthemum Burridgeanum, &c.

AURICULAS require to be top-dressed; do not use the stimulating compounds recommended by the old florists, but good sweet decayed cow-dung and leaf-mould. Give them more water, and examine each under the leaves to see that they are free from vermin.

Fruit Garden and Orchard House.

WALL FRUIT TREES are in a forward state, and in many places the trees are in bloom. Now more than ever the cultivator will need to exercise vigilance and caution. Probably great care will be requisite in giving protection, for we are approaching the season of east winds, and already a bleaker air warns us that just as vegetation resumes its activities earlier than ordinarily, the coldest time of the whole year may come. In any case, those who have the care of wall-trees ought to be ready with protecting material. For all ordinary purposes, we know of nothing to surpass Haythorn's hexagonal netting, made by Haythorn of Nottingham; and it may be right to add that the large-mesh netting is very nearly or quite as effectual as the small, and is considerably cheaper; the fact is, the small mesh is made for people who cannot believe in the efficiency of a large-mesh net; as they will have it, the maker provides it, and charges accordingly.

FRUIT TREES in the orchard-house to have another good soaking at the roots. Give air freely, or the fruit will not set well. Peaches in the forcing-house to be thinned and disbudded judiciously; do not remove all the superfluous fruit and shoots at once. Trees that have set their fruit to have liberal syringing with soft water of the temperature of the house. Figs setting fruit to be kept in a rather dry air, but with sufficient moisture at the root. Vines swelling their fruit to have manure-water and frequent syringings. In thinning, beware of handling the bunches incautiously. Keep outside borders securely covered, as we may have snow when the March winds begin.

SCIONS FOR GRAFTING must be at once heeled in. It is too early to put grafts on; they will take much better if kept back by heeling in for a few weeks to give the stocks a chance of getting in advance of them.

STRAWBERRIES planted last autumn must now be trod between to make the ground firm. A coat of manure may then be spread over the ground, and will greatly benefit them when the drying east winds of March blow the life out of everything except chickweed. Old plantations must be cleared of dead leaves and weeds, and have a good coat of rotten dung laid

on. If it buries the crowns, it will do no harm; they will soon push through. Strawberries in the forcing-pit have plenty of air, plenty of light, and plenty of water. Tepid manure-water will assist in augmenting the size of the berries, but there must be plenty of light and air to ensure flavour and colour.

Greenhouse and Conservatory.

SPECIMEN PLANTS for summer exhibitions and for decorative purposes ought to be growing freely now to give time for stopping, so as to have fine round full heads before allowing them to run into bloom. *Cinerarias* required extra large may be potted on, and if trusses show nip them out. *Pelargonium* will require another shift. Herbaceous *Caleceolaria* the same. A confined condition of the roots will throw plants into bloom quickly if they are in a suitable temperature, but stopping and shifting on will keep them growing larger and larger, and after the last shift a period of six to ten weeks will generally suffice to bring them into bloom, if the pots are full of roots, and stopping is discontinued. Green-fly will now appear in masses where plants are neglected, but a stop must be put to their progress as soon as discovered; every day's delay is mischief.

VERBENAS are very scarce at present. No doubt there will be plenty of stock at the nurseries when bedding-out time arrives, but there can be no harm in making the most of the store plants of good sorts, and it is easy work enough with a good propagating bed to get up untold quantities with a few good stools to cut from.

HELIOPTERES should be pushed forward if an early bloom is required, as they do not bloom so soon from the date of putting in cuttings as many of the summer bedding plants.

PROPAGATION of climbers and tender annuals should now be going on in earnest, and there must be no more delay in propagating bedders if a good early bloom is wanted. *Tropæolums* to be struck from cuttings may be delayed to the middle of March, as they bloom the better, and make less growth, if propagated late; but *Geraniums*, *Fuchsias*, *Petunias*, and *Verbenas* should be cut from as fast as they furnish shoots. If the cuttings show signs of damping, sprinkle a little powdery peat over the surface of the soil, give more air, and raise the temperature. If the cuttings, as soon as rooted, run away into a spindling growth, let them have more light and less heat.

NEW HOLLAND PLANTS and **HEATHS** demand a great deal of attention now to bring leggy specimens into shape, encourage the growth of those going out of bloom, and protect from cold draughts and undue moisture those coming into bloom. Continue to shift such as require it, and any that are looking out of health turn out of their pots, to see if the drainage is right, and the stuff sweet and porous. The powdery peat in which these plants are generally grown at nurseries is best got rid of as much as possible from the roots, taking care not to damage the delicate fibres; and in repotting use plenty of fibry turf and peat, rough lumps, sitting out the fine dust if needful, which will be useful in propagating to pot young stuff in from the cutting-pans.

Forcing Pit.

FROES in the forcing-house must have air, but cold draughts will cause them to cast their fruit. It is equally important not to chill the roots, as may be done by watering with cold well water, &c. The syringe will benefit them, and they require a steady temperature.

PEACHES to be regularly thinned, and the shoots trained in without tying hard. All this sort of work should be done by degrees; to thin out all the surplus fruit at once, or train in all the young shoots close in one day, will be injurious. Besides this, the wholesale way is injurious to the cultivator, for it makes mere business of that which should be a pleasure, and diminishes his interest in his work. The most successful cultivator is he who does everything at the right moment, and ever finds fresh work to do. Daily attentions promote that intimate knowledge of the wants and peculiarities of plants which is one of the finest essentials to success. The temperature of the peach house should now range from 55° to 75°, the latter of course on the brightest days with sun-heat. Trees coming into bloom very profusely must have the bloom thinned, or they will be weakened. Varieties that are shy of setting must be aided by slightly agitating the trellis at midday when the air of the house is rather dry, or by the more niggling but more certain way of brushing the pollen on to the stigmas by means of a dry camel's hair pencil.

PINES in progress must have plenty of water overhead and at the root. Continue to watch that water is not left in the crowns in the after-part of the day. Those in bloom or fruit must not be wetted overhead, and any beginning to colour to have as much air and light as possible, guarding against a chill, and keeping them rather dry. Succession plants must be encouraged.

VINES showing good bunches must have the shoulders tied with worsted or matting. This must be carefully done, as if the bunches are rubbed by the head or hands, rust may ensue. The air of the house where berries are swelling must be kept moist, and it will be well to make a special examination of the border, as this is sometimes wet enough upon the surface, and quite dry a few inches down. In watering, use water of the same temperature as the soil; better a few degrees warmer than colder. Vines for late crops to be kept back, which is not an easy matter in such a warm season as this, when a few days of sun-heat may start them prematurely. Taking off the lights will be the safest method where there is any fear of them starting too soon. If time can be afforded, it will pay in the end to thin the bunches before the flowers open, though very few cultivators have the courage to begin so early.

Stove and Orchid House.

STOVE PLANTS need a general revision at this time of year; those that have been blooming all winter require to be cut back, and encouraged to break, then to be shifted to larger pots if needful, or have top-dressings. Where very large specimens are objectionable, the plants may be kept in bounds by the knife, and to obviate the use of larger pots, turn them out, remove some of the soil from the outside of the balls, and repot them with fresh compost in the same pots. *Justicias* are now going out of bloom, and may be propagated to any extent, to make fine specimens for next season. *Poinsettia pulcherrima* and *Euphorbia Jacquinæiflora* and *splendens* should be grown in quantity, as they are invaluable for conservatory and drawing-room.

STEPHANOTIS FLORIBUNDA ought to be growing freely now in a sweet bottom-heat. This noble stove climber may be grown as easily as a jasmine with sufficient heat and moisture; but it will never bloom freely unless grown freely in the first instance.

DIPLODENIAS should be put in a good heat to start them; and it is best not to tie in too soon, as that arrests growth. One of the secrets of growing these well is to give abundance of water; they are, in fact, marsh plants, or half-aquatics.

ORCHIDS of many kinds come on successively now for their growing or blooming season; but it is not advisable to run up the temperature to a high pitch, because for many days together we have a clouded sky, and there must be some sort of balance maintained between degrees of light which we cannot regulate and degrees of heat which we can. The night temperature for mixed collections should now average 55°, and the day temperature 65°, with a rise allowed of 5° to 10° for sun-heat. As much air as possible should be given on sunny days, as it promotes a complete change of the atmosphere of the house, which is good for all kinds of plants; but be careful not to overdo it, as a chill at this season will be very hurtful.

CULTIVATION OF THE FILBERT,

AND MR. WILLIAMSON'S MODE OF PRUNING IT.

The county of Kent, and more particularly the district round Maidstone, and extending to the borders of Sussex, has been long celebrated for the production of large crops of filberts, and of a much larger size than are generally grown. The following description of their method of cultivation and pruning, by the Rev. Wm. Williamson, M.A., was published in the fourth volume of the "Horticultural Transactions," and we reproduce it as the best reply we can give to J. W. and R. H. J., who have made inquiries as to Mr. Williamson's method.

SOIL.—The first consideration in making a plantation is to select a proper soil, for if that be not congenial to the constitution of the plants, we cannot expect any great success. The soil in which the most experienced cultivators suppose the filbert to flourish best, is a hazel loam of some depth with a dry subsoil. If the subsoil be too retentive of moisture, the trees are apt to run too much to wood, without throwing out those short twigs upon which the fruit is generally produced. That part of Kent where the filbert is chiefly cultivated is a loam upon a dry sandy rock. As a general rule, that soil which is proper for the growth of hops is thought to be also congenial to the filbert.

The filbert requires a considerable quantity of manure; the grounds in Kent are dressed every year, or at least once in two years. Every kind of manure is beneficial, but old woollen rags are found to produce the greatest effect. If Kent had not been a hop county, these would scarcely have been thought of; but as the same soil is congenial both to the filbert and hop, it would soon occur to the intelligent cultivator that probably woollen rags might be as beneficial to the filbert as they are known to be to the hop.

PROPAGATED BY SEEDS, BY SUCKERS, BY LAYERS, AND BY GRAFTING.—Each is practised according to the peculiar object of the cultivator. The method adopted in the district above mentioned is by suckers: they come sooner into bearing, and make stronger plants than either layers or grafts. They are taken from the parent plant generally in autumn, and planted in nursery beds (being first shortened to ten or twelve inches), where they remain for three or four years; they are slightly pruned every year, in order to form strong lateral shoots, the number of which varies from four to six. The most free-growing plants are obtained by sowing the nuts, but they are so coy in coming to a productive state, and so much inclined to degenerate into inferior varieties, that this method is never resorted to in making a permanent plantation. The plants raised by laying and grafting are of more humble growth, and therefore better adapted for small gardens, where the economy of space is an object of importance.

PRUNING.—The method of pruning the filbert being so different from that of every other tree, and being not generally practised beyond the county of Kent, a particular explanation of it will be necessary.

Before any one can possibly prune a tree with propriety, it is necessary that he perfectly understand the mode of its fructification. The fruit of the vine is produced only upon shoots of the preceding year; cherries are grown chiefly on short spurs emitted from the sides of the larger branches; if, therefore, the last year's shoots of the vine or the spurs of the cherry-tree be destroyed, there will be no fruit. Now, in some respects, the filbert is similar in its fructification to both these trees, the bearing branches being always those of the preceding year, similar to the vine; and these branches, if the tree be properly pruned, might with great propriety be called spurs, allowing for the difference between the filbert and the cherry. These short twigs or spurs are not more than a few inches long, every bud of which in a good year produces good fruit. The great object of the following method of pruning is to cause the trees to throw out these spurs in great abundance, and when they are got to a proper bearing state, more than sufficient will be produced.

Though it is the usual practice to plant the suckers in nursery-beds, Mr. Williamson recommends every one to plant them where they are to remain, whether they are intended for a garden or a larger plantation; and after being suffered to grow without restraint for three or four years, to cut them down within a few inches of the ground. When the remaining parts of the trees are well rooted in the soil, five or six strong shoots will be produced. Whichever method is practised, the subsequent treatment of the trees will be exactly the same.

In the second year after cutting down, these shoots are shortened; generally one-third is taken off. If very weak, Mr. Williamson advises that the trees be quite cut down a second time, as in the previous spring; but it would be much better not to cut them down until the trees give evident tokens of their being able to produce shoots of sufficient strength. When they are thus shortened that they may appear regular, let a small hoop be placed within the branches, to which the shoots are to be fastened at equal distances; by this practice two considerable advantages will be gained—the trees will grow more regular, and the middle will be kept hollow, so as to admit the influence of the sun and air; but this in a large plantation would be almost impossible, nor indeed is it necessary, though in private gardens, where regularity and neatness are almost essential, it ought to be practised.

In the third year a shoot will spring from each bud; these must be suffered to grow till the following autumn, or fourth year, when they will be cut off nearly close to the original stem, and the leading shoots of the last year shortened two-thirds.

In the fifth year, several small shoots will arise from the base of the side branches which were cut off the preceding year; these are produced from small buds, and would not have been emitted had not the branch on which

they are situated been shortened, the whole nourishment being carried to the upper part of the branch. It is from these shoots that fruit is to be expected. These productive shoots will in a few years become very numerous, and many of them must be taken off, particularly the strongest, in order to encourage the production of the smaller ones; for those of the former year become so exhausted that they generally decay, but whether decayed or not they are always cut out by the pruner, and a fresh supply must therefore be provided to produce the fruit in the succeeding year.

The leading shoot is every year to be shortened two-thirds, or more should the tree be weak; and the whole height of the branches must not be suffered to exceed six feet. Every shoot that is left to produce fruit should also be tipped, which prevents the tree being exhausted.

The filbert is a monoëcious plant, and consequently produces the male and female blossoms separately on the same tree; the slender scarlet filaments which are seen issuing from the ends of the buds early in spring are the female or productive blossoms; the barren or male blossoms are formed on long cylindrical catkins, which fall off as soon as they have performed their office. In pruning, care must be taken to leave a due supply of these to fructify the female blossoms, or our previous trouble will be useless; this may be done without difficulty, for they are perfectly visible at the time of pruning.

The method of pruning above detailed might, in a few words, be called a system of spurting, by which bearing shoots are produced which otherwise would have had no existence.

It frequently happens that a strong shoot springs from the root; and should any of the first year's or leading branches be decayed or become unproductive of bearing wood, it would be advisable to cut that entirely away, and to suffer the new shoot to supply its place, which is afterwards to be treated in the same manner as recommended for the others.

Old trees are easily induced to bear in this manner, by selecting a sufficient number of the main branches, and then cutting the side-shoots off nearly close, excepting any should be so situated as not to interfere with the others, and there should be no main branch directed to that particular part. It will, however, be two or three years before the full effect will be produced.

"But though this method of cultivation has long been celebrated, yet it does not appear to me," says Mr. Williamson, "so particularly successful as to deserve the encomiums which have been bestowed upon it; for though thirty hundredweight per acre have been grown in particular grounds and in particular years, yet twenty hundredweight is considered a large crop, and rather more than half that quantity may be called a more usual one; and even then the crop totally fails three years out of five, so that the annual average quantity cannot be reckoned more than five hundredweight per acre.

"When I reflected upon the reason of the failure happening so often as three years out of five, it occurred to me that possibly it might arise from the excessive productiveness of the other two, the whole nourishment of the trees being expended in the production of the fruit, and that consequently they might be unable properly to mature the blossom for the following year. We know that peach and nectarine trees may be so pruned as to force them to bear a superabundant quantity of fruit in some one year; but we find that a regular crop in succession is thereby prevented, and that too for several years. In order to ensure fruit every year, I have usually left a large proportion of those shoots which from their length I suspected would not be so productive of blossom-buds as the shorter ones, leaving them more in a state of nature than is commonly done: not pruning them so closely as to weaken the trees by excessive bearing, nor leaving them so entirely to their natural growth as to cause their annual productiveness to be destroyed by a superfluity of wood. These shoots, in the spring of the year, I have usually shortened to a blossom-bud, for the reason before given.

"The great art of pruning is to produce the greatest quantity of fruit without any injury to the crop of the succeeding year, which, in my opinion, is not done by the Kentish method. But by observing the rule I have laid down, though the trees do not perhaps bear so great a weight in any one year as by the method before detailed, yet the crops in the whole are certainly not less, with this great advantage both to the public and private grower, that a moderate and regular crop is ensured in every successive year; I think that by this plan the average might, in the whole, be greater. The year 1819 was a very productive one: I grew two hundredweight of filberts (weighed when gathered) upon fifty-seven trees, the greater part of which were not seven years old (reckoning them from the time of their being cut down), and growing upon 360 square yards of ground, which is after the rate of twenty-seven hundredweight per acre; and upon part of the ground ten more trees are now planted, which, if they had come to a bearing state, would have increased the quantity to more than is considered an extraordinary crop, besides having grown upon the older trees a moderate but regular quantity for several years preceding. I am the more confirmed in my opinion that the failure is caused by excessive bearing, by observing that there is very little blossom on my trees this spring, which has not been the case in former years.

In order to strengthen the tree as much as possible, care should be taken to eradicate the suckers from the roots, which is effected by exposing the roots, a moderate distance from the stem, to the frost of winter. The excavation in the spring is filled with manure.

As filberts are several years in coming to perfection, it is usual to plant hops, standard apples, and cherries among them. When they come to a bearing state, the hops are destroyed, and the fruit-trees suffered to remain. The ground is then planted with gooseberries, currants, &c., and an under-crop of vegetables is likewise frequently obtained. If this were not practised, the crop of filberts alone, except in particular years, would not defray the expense. The distance at which filberts are planted must depend upon their being mixed with other fruit.

Literature.

Dr. G. A. Pritzels Catalogue of Flowering Plants and Ferns, compiled from the Botanical and Horticultural Literature of the 18th and 19th centuries. [Verzeichniss der Abbildungen seltener Böhrender Pflanzen und Farne-krauter aus der Botanischen und Gartenliteratur des XVIII. und XIX. Jahrhunderts in alphabetischer folge zusammengestellt. Von Dr. G. A. Pritzel.] London: Williams and Norgate.—This is a Berlin publication of considerable importance to botanists and cultivators of plants. It is an

alphabetical list of all plants figured and described in works of authority published during the past 150 years, with references to figures and descriptions. The list of authorities prefixed comprises in all 94 works, the oldest of them, a French work on the plants of Canada, bearing date 1635, but the majority belonging to the present century. In the whole number there are enumerated 28 English books, or more than a fourth part of the whole. Amongst the English books we find Lowe's Ferns, Hooker's Himalaya, New Zealand, &c., Warner's and Bateman's works on Orchids, Lawson's "Pinetum," Seeman's "Flora Vitiensis," and Boott's "Genus Carex." About a dozen American works are entered, such as Asa Gray's Botany of the United States Exploring Expedition, Torrey's Report on the Mexican Boundary, and Nuttall's "North American Sylva." There is of course no lack of important continental works, such as Blume's "Museum," Fee's "Genera Filicum," Née's "Sammlung," Reichenbach's "Xenia Orchidacea," and Schott's "Aroidæ." Nevertheless, we cannot accept this as a satisfactory list of authorities, and regret that Dr. Pritzel did not include such authors as Lindley and Gordon, and he might even have gone back to the "Hortus Kewensis," and a few plants would have turned up that have been overlooked by later authors. Lawson's Pinetum is not advanced sufficiently to furnish references for conifers generally, and Gordon's excellent work would stand well in its stead. However, the result of the compilation from the 94 works enumerated, together with the "Garten Flora," the "Revue Horticole," the "Botanical Magazine," and a few other periodicals, is a list of 20,700 plants. One of the specially good features is a reference under the head of each natural order to the authority for its foundation, and the best exposition of its characters; and it would have been another good feature to have printed the orders in a different type to the names of genera: the only distinction attempted is what printers call "spacing out," which is insufficient. But forgetting these small defects, we are bound to praise the industry and accuracy of the author, and heartily recommend the work to all who can make any use of a mere list. It will be especially useful to botanists, nurserymen, and botanical writers, and is the most comprehensive key to information upon plants that we have at command at the present time.

The Children's Friend, and The Infant's Magazine. Published by S. W. Partridge.—The issues of these for 1866 are tastefully bound in coloured boards, and admirably adapted for presents, school prizes, and for every household that is blessed with the prattle of children. We confess to having spent many hours over these two books, and having at last put them down with regret, they are so truly fascinating for both young and old. Readers who are not acquainted with these publications will be astonished to hear that they are richly illustrated from the pencils of Birket Foster, J. Gilbert, Harrison Weir, Mr. H. Anelay, Mr. Ansdell, and other artists who rank highest among designers for books; and the faithful engraving of their works by Messrs. Dalziel and Mr. Knight ensures faithful rendering of the subtlest touches and richest effects. The "Half Holiday," at page 104 of the *Children's Friend*, "We are Seven," at page 45 of the same, and Birket Foster's lovely landscape at page 131 of the *Infant's Magazine*, are such gems as we might look for in guinea gift books; indeed, these works are quite as much entitled to notice as works of high art as they are for their perfect adaptation in style and subjects to teach the young idea how to shoot. We hope this notice may lead many of our readers to order these eightpenny books, for if not acquainted with them already, there is in store for them a delightful surprise.

The Intellectual Observer for February contains a paper by Mr. W. Duthie on ancient Jewellery, which is admirably illustrated in gold and colours; the paper called the "Trial of the Pyx" is a valuable addition to the many papers which have already appeared in this work on subjects relating to the Mint and processes of coining. There is a further contribution on the growth of shells, from the papers of the late Dr. S. P. Woodward, an interesting paper on the Mangrove by Mr. Jackson, of the Kew Museum, and essays on Telegraphy, Coal Supply, Fossil Forests, the Mammoth, and various matters connected with archaeology.

The Floral World for February contains a paper on Exotic Ferns adapted for open-air ferneries, with a very effective portrait of Woodwardia radicans; also practical articles on raising sub-tropical plants from seed, on the cultivation of the Auricula, further contributions on select herbaceous plants, and a variety of useful notes and suggestions on the work of the season and the fashions in floriculture.

Our Own Fireside for February is full of entertainment and rich in variety. In the scientific department is a capital sketch of Esquimaux life, with illustrations, and in another department is a most entertaining selection of anecdotes illustrative of animal sagacity, accompanied with two characteristic pictures by Mr. Harrison Weir.

The Ladies' Treasury for February is richly illustrated, and full of entertainment and variety. Mrs. Warren takes care to mix a due proportion of light reading with the serious historical, domestic, and scientific matters which form the staple literature of this excellent work.

The Journal of Botany.—The February number contains a notice of a new genus of Corallines by Dr. J. E. Gray; a translation of a paper on the tomentosa section of the genus Ra, by M. A. Deseglise; notes on the finding of Eriophorum alpinum and Acorus calamus in Ireland; a smart review of Mr. Clarke's little book on the botany of Andover, and the usual omnium gatherum of miscellaneous matters.

The Gardener for February contains papers on plants adapted for grouping, on the cultivation of geraniums as pyramids, on grape-shanking, and the culture of Luenlia gratissima, &c., &c.

Received—*The Watchmen of Ephraim, Old Jonathan, The Gospel Magazine, The Shipwrecked Mariner.*

Downie, Laird, and Laing, Frederick Street, Edinburgh, and Forest Hill, London.—*Descriptive List of French Hybrid Gladioli.*—Contains descriptions and prices of about 250 varieties, with a selection of cheap kinds for clumps and beds.

Drummond Brothers, 52, George Street, Edinburgh.—*Catalogue of Vegetable and Flower Seeds.*—We observe an offer in this list of a good strain of variegated kale for the embellishment of drives and shrubbery borders in winter. The selections are admirable, and the catalogue is nicely got up.

T. Pierpont, Warrington.—*Catalogue of Vegetable, Flower, and Agricultural Seeds.*—In the list of peas we notice "No. 1 Extra," described as next to First Crop in time, and in other points superior. This surely cannot be a *bona fide* distinct variety. This is a first-rate seed list; the cultural notes short and good, and the selections cut down to the fewest possible, and those the best.

Correspondence.

NIGHT STOKERING.—Mr. Clarke says at page 10 of this year's volume of GARDENER'S MAGAZINE, "Night stoking is abolished: how ridiculous!" I am an amateur, and my own stoker, and to keep my house at not less than 40° during such frosts as have visited us lately has been my aim; and it has been done by my stoking only twice in the twenty-four hours, viz., about 8 a.m. and 8 p.m. I have no damper, but when fixing I was very particular to get every crevice closed to prevent admission of air to the fire, except through the ash-pit door. In this door there is a slide that closes, or partially so, six openings cut out of the ash-pit door; each opening is about 1½ in. by ¾ in. By carefully leaving the slide to regulate the supply of air to the fire, and by a little attention to filling in the fuel, I can either burn it out in five or six hours, or keep it burning slowly fifteen or sixteen hours. Let Mr. Clarke try this plan carefully, and give the result in your pages as to night stoking, and also as to the cost of fuel—mine is coke broken and small coal such as blacksmiths use. Reading some time ago, I think in the GARDENER'S MAGAZINE, that the great point was to regulate the supply of air to the fire, drew my attention to the subject, and I feel convinced this simple plan is the main point in the so-called patent stoves. My ash-pit door is closed in by a sheet of iron, and a piece cut out of the centre for the door, with slide; this was suggested by the writer, who now considers it, after a fair trial, to answer admirably, and it is the stoker's sheet-anchor against night-work. I only wish now I had read your remarks on copper boilers sooner, as when worn out there is a value in the old material—not so in iron; and we amateurs could have our own fancy in the shape of boilers, a matter of importance to a fussy old fellow like me, who was not content even with your suggestion to hang woollen strips over the openings to admit air, so I had slight wood frames made, and sheets of perforated zinc nailed on to fit the openings. These pleased me well, and experience teaches me to prefer the zinc. CHARLEY.

Replies to Queries.

Broccoli.—Centranthus.—We had a head of Cattell's Eclipse last summer, the weight of which was a trifle under 4 lb., and for beauty and flavour could not be surpassed. We have not grown Williams's Alexandra, but it has been reported to us on good authority to be one of the best varieties yet introduced to cultivation to stand the winter, superseding Snow's Winter White and Knight's Protecting. The following are reliable sorts: Carter's Champion, Dalmeny Park, Cornish White, Frogmore Protecting, and Elkton's Mammoth.

Asparagus.—J. B.—It is quite a mistake to suppose that there are several sorts of asparagus. There may be many names in vogue, but asparagus seed from one place will, as a rule, be as good from any other. Of course it is possible to obtain bad seed, but there is but one form of the plant. Its condition, whether fat or lean, is the result of cultivation.

Removal of Plant Houses, &c.—Little Florist.—If you took the ground upon the understanding that you were to occupy it as a florist, growing thereon plants for sale, you can certainly remove your houses, plants, &c. If you took the ground as a person not engaged in trade would do, and on the *prima facie* supposition that you would cultivate the ground for your pleasure only, the landlord can legally prohibit the removal of whatever is *bona fide* fixed in the soil, but you may remove whatever merely rests on the soil. Thus all trees and shrubs, and even a box edging cannot be removed; generally speaking, plant houses may not be removed, except where they are merely placed on the surface—for instance, the Paxtonian houses made by Messrs. Hereman. As to the agreement you have, and which is not stamped, we suppose it to be null and void; but the value of an unstamped agreement is quite a question for a solicitor. We have many queries relating to questions such as the above, and as a rule we pay very little attention to them, for they too frequently bear the appearance of attempts to get legal advice gratis. We do not profess to give legal advice, or to know anything of law, and we would rather offend any number of correspondents by declining to answer their queries than offer an opinion on a subject of which we are confessedly ignorant.

Broccoli Seed.—Veritas.—It is impossible for us to name one seedsman out of perhaps fifty equally respectable and reliable, without manifest injustice. In respect of novelties and specialities, we do give the names of traders who introduce them, but the subject you inquire about may be obtained of any really first-class house.

Barometer.—Under Gardener.—Meteorological instruments are usually read off at 8 a.m. or 9 a.m. daily. A barometer should be hung so that the register of 30 inches is on a level with the observer's eye. A nail driven at 5 feet 9 inches from the ground will in ninety-nine cases in every hundred just suit for banging a barometer. To read the barometer, slide the vernier up or down till it marks exactly the top of the mercurial column, and then note the figure registered in inches and tenths. No one need trouble about hundredths for any practical purpose. Registering thermometers are usually placed about four feet from the ground, but systematic observers use many instruments placed in various positions.

Planting Potatoes, &c.—J. Wright.—The sooner the heavy ground is dug the better; let it be laid up ridge and trench by a good workman. At planting time, instead of dibbing in the sets, lay them in the trenches and throw the soil from the ridges down upon them. This plan produces a well-pulverized and aerated seed-bed. Of course the trenches should be as far apart, or half as far apart, as the rows are to be. In putting new gravel on an old road, it is necessary to pick over the old surface, or the new material will not incorporate with the old.

Books.—J. Wright.—Much sound information, intelligibly conveyed on such subjects as landlord and tenant, I O U's, partnership, insurance, duties of executors, &c., &c., may be found in "Rights and Wrongs," by Albany Fonblanque, published by Routledge and Co. The price is something under 5s.—W. Wilson.—Bentley's "Manual of Botany," published by Church-hill at 12s. 6d., and Grindon's "British and Garden Botany," published by Routledge at about the same price, will suit you. One of the best books to refer to in writing garden labels is Grindon's "Manual of British and Foreign Plants," published by Pitman, the price 3s. or thereabouts. It is a pity the price is not stamped on the backs of books; it is impossible always to remember it, and we should never answer queries at all if we had to hunt through catalogues for the price of every book inquired about.

Primula Seed.—Miss Harmer.—It is time now to sow the first pinch of seed. The surest way to proceed is to nearly fill the pans with manure that

has been two years rotted and then sifted. Sprinkle the seed upon the surface, and do not cover the seed with soil, but lay over the pan a sheet of glass smeared with clay to render it nearly opaque. If the soil becomes dry before the seed sprouts, put the pans in a vessel containing one or two inches depth of water till the soil is quite moistened. A warm house or hotbed is the proper place for the seed-pans. As soon as the plants appear, remove the glass, and as soon as possible pot them off separately.

Ivies—Pampas Grass.—J. A. Stephenson.—The largest collection of variegated and other ivies in the trade is in the nursery of Messrs. E. G. Henderson and Co., Wellington Road, St. John's Wood. Messrs. Lucombe, Pine, and Co., of Exeter, have a considerable variety, and the entire stock probably of the creamy-leaved tree ivy referred to in our remarks on the embellishment of the garden in winter. You will probably not easily obtain dwarf bush ivies ready for plunging out, but you will easily obtain plants that by a few years' training may be made very effective. We have never known the pampas grass to flower the first year from seed.

Ground Vinerias.—H. Smith.—The vines are planted *outside*, close to the end of the frame. The training is of no consequence at all; a few pegs thrust into the ground between the slates suffice to keep the rod in its place. There is no rafter; in fact, the vine lies on the slates with which the soil under the frame is covered, and the bunches of grapes in like manner rest on the slates, but which "of course" does not "spoil them." When two vines are grown in one structure, the slates are merely laid on the ground as if only one vine were in it, but as the frame is wider, wider slates will be required. In the case of two vines, they are kept in their places by pegs twelve or fourteen inches apart. There is one difficulty in communicating information on ground vinerias, and it is this—the whole affair is so extremely simple that it appears to a practical writer as if there was nothing to describe, and so some few points about which beginners may wish to be informed are pretty sure to be omitted altogether. It appears to be highly beneficial to the grapes to rest on clean slates under a glass roof, for the heat they are thus subjected to is such as they have when growing on rocky and sandy soils in the native countries of the vine.

Seedling Cinerarias.—J. E. Rhug.—Of the three flowers enclosed in your letter, one is a real beauty, being of medium size, with very broad florets overlapping, so as to present a smooth and perfect circle. It has rather too large a disc, but is very substantial, and the colour a fine deep magenta-crimson.

Bedding Plants from Seed.—J. H.—We cannot understand from your letter what plants you have lost, but as you ask for the names of a few subjects that can be got up from seed, the following notes may be of some use: *Amaranthus melancholicus*, rich claret-coloured foliage; *Lobelia erinus speciosa*, blue; *Dwarf French Marigold*, and the pretty miniature marigold called *Tagetus signata pumila*, orange; *Portulacca Thellusoni*, crimson, fine for a hot sandy or stony soil; *Ricinus communis*, superb foliage, useful for bold groups; *Tropaeolum minor* of several kinds, the Tom Thumb section being the best to raise from seeds; *Viola cornuta*, slaty-blue. Asters, Balsams, Stocks, Candytufts, and the dwarf Campanulas are valuable, but are not so well adapted to plant out once for all as the foregoing, as they are less lasting.

Seakale Beet.—R. Simson.—We are not at all in raptures with this vegetable. To see it growing is to be filled with temptations to see it cooked, for it is most elegant with its thick ivory-white stems and elegant white-veined leaves. But however carefully cooked it comes to table a bad colour—a sort of greenish-white washed with black. We have seen it tried in the fairest way possible, but it never could be served a good colour. Then it has but little flavour, and is only an apology for a vegetable. Any one with an eye and a palate would prefer a dish of any sort of greens to this imitation of seakale.

Peas.—S. W.—It is no use to expect a fine dish of peas from impoverished soil. Trench the ground if it is deep enough to allow of it, and put in a liberal dressing of manure, stirring it into the earth at the bottom of the trench. Sow 4 inches deep, and put sticks in good time.

The Editor is desirous of recommending for employment, where three or four (or more) hands are kept, a Head Gardener. He is a man of ability and character; possessed of experience in every department of garden work, and of good deportment, obliging, and thoroughly businesslike in his habits. Communications addressed to the Editor at 119, Aldersgate Street, London, E.C., will be forwarded as soon as received.

EFFECTS OF THE FROST ON ROSES—MARECHAL NEIL.

In the article on the "Effects of the Late Frost on Standard Rose Trees," I quite forgot to mention *Marechal Neil*. Last April two plants of it came here along with some new roses from Messrs. Wood and Son, of Maresfield. In May they were planted out against a south wall, and in due time they bloomed. Although the plants (pot plants) were weak, I think I never saw more beautiful blooms. It is a lovely yellow rose; colour fine and good. The flower droops, on account of the stem being weak, which I consider a merit in the habit of the plant, as no rain can get to the centre of the flower, nor sun to spoil its beauty. My two plants, I am happy to say, are not affected by the frost. I protected them with a double coat of spruce firs. *Solfaterre*, *Triomphe de Rennes*, and *Madame Falcot*, protected in the same way, were killed. I therefore conclude that it is much hardier than any of those varieties. I budded fourteen briers with *Marechal Neil*; it takes on the brier more freely than any rose I know; not one bud failed, and some of them were weak and bad.

I never take the wood out in budding any variety; I find it much better practice. The French, I believe, never take the wood out of the bud. I merely cut a small shield the size of a barleycorn, and insert it neatly; I do not tie close, but leave a space between each two folds, which leaves room for the shoot to swell. The frost killed all my *Marechal Neils* in dormant bud, fourteen in number.

Great Fencote, Bedale, Yorkshire.

HENRY TAYLOR.

TO KILL INSECTS IN GREENHOUSES.—Mr. W. W. Saunders stated at a meeting of the Entomological Society, that for some years he had used spirits of wine in his greenhouses for cleansing plants and clearing them from insects; he mixed the rectified spirits and pure water in equal proportions, and this mixture, which was found to answer better than undiluted spirit, was applied with a brush. It was very efficacious in the destruction of the common mealy-bug (especially when young) and other common pests, and he recommended it as worthy of application in the greenhouse generally.

PATERSON'S FAMED SEEDLING POTATOES.

THE best Disease Resisters, the Heaviest Croppers, the best Flavoured. Retail Agents in London, HOOPER & CO., COVENT GARDEN MARKET, LONDON, W.C. Priced list and testimonials free on application.

Marshall's Prize Parsley, per packet 1s. Gibbs' Parsley-curl'd Borecole, per packet 6d. Free by post.

These are the FINEST SELECTIONS ever introduced, and have carried off FIRST PRIZES wherever exhibited. SMITH & SIMONS, 1, BUCHANAN STREET, GLASGOW.

To Cucumber Growers.

G. WALKLING, SEEDSMAN, FLORIST, and CUCUMBER GROWER, begs to offer CUCUMBER SEED of two first-class sorts at 1s. 6d. and 2s. 6d. per packet—Walking's Prolific, and Walking's Solid Green. Likewise PLANTS of the two kinds, in large or small quantities.

G. WALKLING, FLORIST, SEEDSMAN, AND CUCUMBER GROWER, NORTH ROW, LEWISHAM.

Patent Indoor Plant Cases.

(To which a Prizo was awarded at the Royal Horticultural Society's Exhibition.)

Sole Manufacturer, JAMES GRAY,

HORTICULTURAL WORKS, DANVER ST., CHELSEA, LONDON, S.W.

THE Patent Indoor PLANT CASE is one of the most useful gardening novelties of the day. It is a handsome ornament for the Drawing-room or Sitting-room, and at all times forms a fresh, pleasant, and interesting object to the mind and eye. It is always under command, and will preserve many of the most tender Exotic Plants through the severest winter with comparatively little of the trouble and annoyance attending the use of Lamps, Gas, and Heating Appliances of any other kind.

To all who have a taste for the cultivation of Indoor Plants, for raising Seedlings, Striking Cuttings, &c., this Case will be found an inestimable boon.

The PATENT PLANT CASE is highly approved and recommended by Professor Lindley, and Messrs. Veitch, of the Royal Exotic Nursery, King's Road, Chelsea.—Sizes and Prices on application.

Improved Fruit Tree Culture.

Just published, enlarged and improved, the 14th edition of the

MINIATURE FRUIT GARDEN. By THOS. RIVERS. Price 3s. London: Longman and Co.; or, free by post, from the Author, Swanbridgworth, Herts.

GENUINE GARDEN SEEDS.

WM. CUTBUSH AND SON'S CATALOGUE of VEGETABLE, FLOWER, and FARM SEEDS, post free on application.

Nuneham Park Onion.

WM. CUTBUSH & SON have great gratification in announcing that this SUPERB NEW ONION has in every instance, where shown, obtained the First Prizes, and numerous Testimonials have been sent to them from various parts of the country, confirming the opinion that it is the largest and heaviest cropper of all Onions. It is also of exceedingly mild flavour, and keeps as long as any variety extant. In Sealed Packets, 2s. 6d. each,

No more can be supplied to the trade this season.

HIGHGATE NURSERIES, LONDON, N.

HAMMERSMITH.

The Stock of a Greenhouse and Horticulture Builder.

MESSRS. R. S. SWAIN & SON have received instructions from the owner, Mr. JOSEPH SMITH, to Sell by Auction, on the premises, Pine Cottage, Hammersmith (close to the "Queen of England"), on Wednesday, the 27th February, 1867, at One o'clock, the whole of his well-seasoned Stock of GREENHOUSES, consisting of Span and Lean-to Roofs, with Ends, Sides, and Stages, 4 feet by 12 feet, 33 feet by 10 feet, 30 feet by 10 feet, 23 feet by 12 feet 9 inches, 24 feet by 9 feet 6 inches, and others of smaller dimensions; one, two, and three light Frames; a large quantity of Lights, and Effects.

May be viewed the day prior and morning of Sale. Catalogues had on the premises, and of the Auctioneers, The Lodge, Notting Hill, W.

First Prize at the International.

H. CANNELL'S SELECT AND DESCRIPTIVE CATALOGUE and AMATEUR'S and GARDENER'S FLORAL GUIDE for 1867, is now ready, free for four stamps, with every particular how to grow, show, and get the First Prizes for Fuschias and Verbenas, &c. A full and correct description of all Bedding Gems for the Season.

FUSCHIA NURSERY, WOOLWICH.

TANSLEY NURSERIES,

NEAR MATLOCK, DERBYSHIRE.

JOSEPH SMITH, SEN., invites Planters and the Trade to inspect his Nursery of 80 Acres of high land. The soil is of a fibrous nature, and the Plants take up with excellent roots, such as to ensure the best success in their removal.

The Nursery contains many Hundred Thousands of RHO-DODENDRONS, COMMON and PORTUGAL LAURELS, BOX, BROOMS, BERBERIS, HOLLIES, PRIVETS, YEWs, &c. The FOREST TREES are very extensive, of all the leading kinds; there are 15 Acres of LARCHES, of difforunt sizes, and all others in proportion. Prices moderate, which can be had on application as above.

BEAUTIFUL FLOWERS! BEAUTIFUL FLOWERS! Cocoa Nut Fibre Refuse for Sale.

THIS useful Material, the superiority of which over Manufactured Manures for strengthening the growth and improving the blossom of flowers, is now fully established by testimonials from Floriculturists and Gardeners from all parts of the United Kingdom, may be had in quantities of not less than two sacks, delivered free to any of the London booking offices, at 2s. 6d. per sack, each containing six bushels, sack included, on receipt of post order or postage stamps, addressed

The Gardener's Magazine.

SATURDAY, FEBRUARY 23, 1867.

ACCLIMATIZATION IS POSSIBLE WITH BOTH ANIMALS AND PLANTS to a limited extent, and the extent of the possibility is much more limited than is generally supposed. It is a popular fallacy that an animal or plant fitted by its organization for residence in a hot climate may by degrees be adapted to a cold climate; but experience proves that *the limits of adaptability are fixed* in the constitution, and the art of acclimatization consists, not in altering the constitution, which is impossible, but in discovering the limits of its adaptability. Our domestic animals are wonderfully adaptive in constitution: we find sheep and oxen thriving in Spain and in Denmark; horses attain perfection in the sunny lands of Arabia, and have vigour and endurance amid the snows of Russia. Even the tiger, which is peculiarly a tropical animal, goes as far north as 45°; and the reindeer, which is peculiarly an arctic animal, goes as far south as 45°; and thus tiger and reindeer may meet, and the result may be as pointed out by Sir Charles Lyell in his grand work on the antiquity of man—some curious problems for geologists, when the bones of these two animals are found embedded side by side in the same rocky stratum. Mr. Burley remarks, in his interesting paper on this subject, that animals have a wider range of adaptability than plants, which is true as a rule; but there are exceptions. The chimpanzee never lives long when removed from its native land; it has a small capacity for constitutional adaptation to climates colder than those in which it is met with wild; but perhaps our common groundsel, compared with the chimpanzee, would, if one comparison were sufficient, prove that plants have a wider range of adaptability than animals. We are apt to lose sight of the fact that every separate organism has a constitution of its own; yet it is so. Look at a bed of Sweet Williams this moment. We will suppose the seed was sown last year, and that it all came out of the same gathering, yet we shall find in the bed many plants quite unhurt by the recent severe weather, some browned and disfigured for the present, but prepared to recover quickly, and a few have been killed outright. If we knew nothing of the race, and had the dead plants only to furnish us with ideas respecting it, we should be bound to decide that the Sweet William is not a hardy plant; but having more experience, we pronounce that it is hardy, and that the losses out of the bed are exceptions to the rule. Now it is a very easy matter to be led astray by the behaviour of plants respecting which we have had fewer experiences than with Sweet Williams—or to be more dignified, as this is a "leader," we will say *Dianthus barbatus*. We find that certain plants introduced from foreign countries where the mean temperature is higher than that of Britain, and the minimum temperature is never so low as here, bear our ordinary winters with equanimity, and we may, if given to delusions, conclude that cultivation has "acclimatized" them. But there occurs an extraordinary winter, such as that of 1860-61, or 1867, and lo! the delusion is undone; we find that our foreign pets have in no way changed in respect of constitutional power to bear excessive cold; they are changed, because death has made an end of them; the limits of their adaptability were overpassed, and life ceased because the conditions of life were withdrawn. In every class of domestic animals and cultivated plants there are to be found races needing warmer climates than others, and races that will bear greater degrees of cold than the class generally. Thus our Leicester and Cotswold sheep, when taken to Spain to cross with merinos, soon lose their peculiar fleeces, and are of no use at all. So the merino, transferred to the highlands of Scotland, changes its garb, and ceases to be the silky-coated creature it was originally, and these are cases of true acclimatization. But take either of these races to the hottest parts of tropical Africa, and they perish; take them to Esquimaux land, and they perish; the most experienced adept at acclimatizing fails in such a case. It is the same with plants. Advancing pea, one of the most useful in cultivation, is lost entirely if sown

in January in the north of Scotland; but Lynn's Marrow braves the cold, and is hardier than any promiscuously selected fifty varieties of peas, though derived, no doubt, like the rest, from *Pisum sativum*. That animals should be better fitted than plants for ranging over wide latitudes, is consistent with their power of locomotion, for the scheme of nature is perfect, and if an organism is endowed with volition and powers of locomotion, it must encounter climatic influences differing more or less from those which pertain exclusively to its home. Indeed, its home is the spot where the climate, soil, and food suit it most completely. Yet, as we have seen, it may live, and that not unhappily, in places where there is a defect of warmth and food, as is the case with the horses of Shetland, which are dwarfed by cold and short commons. But it is the peculiarity of the nutritive system of animals that explains their larger powers of adaptability. The generation of heat, and the constancy of that heat when the trial does not exceed a certain limit, are the two grand facts in the philosophy of acclimatization. Corresponding with the action of the nutritive system is that of development, which comprises the fashion of the outward covering, as well as the solidity of the muscular fibre and the proportion of fatty tissue. We happen to know a fine hog that was purchased in Scotland and taken to Teneriffe. The skin of the animal was covered with a thick down, but after a few years' residence in a hot climate, the down disappeared, and the original bristles became more like bodkins than the pliant defences they were before, showing plainly that this was a case of acclimatization. The elephant bears the rigours of this climate tolerably well if not rashly exposed in winter, and the celebrated Siberian elephant that was dug out of a block of ice, and found in such a good state of preservation that dogs ate the flesh, was a veritable woolly elephant, and a much better example perhaps of wool than Mr. Barnum's woolly horse. On the other hand, plants have no nervous system, no pumping central organism analogous to a heart, and no source within them of a constant temperature. Hence, those that are not adapted to endure a condition of freezing die when subjected to low temperatures, and we could not hope to acclimatize them if thousands of years were given us for the experiment. We consider the *Araucaria imbricata* to be hardy, and it has been long enough in the country to be thoroughly acclimatized, if such a thing were possible; yet we could point to a garden where at the present time there are a number of trees completely killed by the recent frost, the value of which, previous to their destruction, cannot have been less than £500. The very trees now killed survived the winter of 1860-61, though in the same garden in that disastrous season hundreds of Araucarias were destroyed. The frost on that occasion may be said to have selected such as were unfit to endure it, and on the occasion of the frost of January last it did precisely the same.

The endurance of frost by plants is not wholly a question of its intensity. After a hot summer, finishing off with a bright autumn, the majority of trees in our gardens will bear without harm any degree of frost possible in this climate. But after a cold summer and a wet autumn, a sharp frost will kill the soft shoots of apple, pear, plum, and peach trees—will kill, in fact, almost anything that we reckon hardy, even the youngest shoots of ivy and Virginian creeper. The reason why the Japanese subjects have suffered so much of late is probably not wholly the degree of cold, but because they have not the summer heat they enjoy at home, and so their juices and secretions are not in so perfectly an elaborate state as is requisite for a complete state of rest when winter overtakes them. Acclimatization consists much less in attempts to alter the constitution of the subject sought to be acclimatized, than in discovering the limits of its adaptability. We know nothing of the hardness of a plant until it has been tried, and there is a value in the humblest of experiments in testing the relative hardness of animals and plants, if faithful reports of facts are published. Man is undoubtedly the most adaptable of all creatures. There is not a spot on the globe on which he can set his foot but he can manage to live on it, however hot or however cold. But then clothing, fire, highly artificial forms of food and drink, come to his aid, and in one case he may derive health and strength from pumpkins and water, and in another case from potted beef and brandy. Plants have no such resources; their limits of adaptability are narrow, comparatively speaking, and it is vain for us to contemplate changing their natures. All we can hope to do is to discover what are the extreme conditions within which life is possible.

CULTIVATION OF THE CHRYSANTHEMUM IN POTS.

Having been requested by many amateur cultivators to offer some remarks on the system I have followed in the production of my specimen chrysanthemums that have been exhibited at the November shows during several years past, I have drawn up a few notes in which I have endeavoured to state the case briefly but completely. I think it only proper to remark, by way of preface, that the hundreds of prizes I have won have been obtained by means that are within the reach of every amateur cultivator, and indeed I would say more, that the amateur ought to beat the trade grower, for one of the greatest secrets of success is constant attention to the plants; this the private grower has more time for than the nurseryman. I would emphasize the remark that *constant attention* will do more than the most extraordinary skill fitfully exercised. To excel in this department of outdoor recreation, in common with every other pursuit, the grandest quality is *perseverance*. By being constantly among his plants, and taking a pleasure in *every* stage of their progress, the whole year round, the cultivator learns to understand their wants, and can tell at a moment's notice whether or not they are in health, and in the event of any ailment occurring can take steps to remove it before the plants are irreparably injured; whereas intermittent attention may at any time result in serious disasters, while the possessor of the plants is ignorant of what is going on. It is on record in the reports of the horticultural journals that I have been for many years a successful prize-taker in every part of London, and on some few occasions in distant provincial towns. I can honestly say that I owe very much of my success to my *own* love of the plant. I am unremitting in my attention; I superintend the whole routine of cultivation followed, and watch over my plants from first to last, at home and abroad. The splendid exhibition which I have yearly in my show-house would amply repay me if I were less successful at exhibitions, and I am convinced that any lady or gentleman who has not hitherto thought much of the chrysanthemum needs only to behold once, in the dull month of November, the splendid display of colour which a well-grown collection presents, to become thorough converts to the patronage of this useful and most beautiful flower, which demands little from us, and which keeps its glories veiled till the summer is past and gone, and then revives the summer when all around it is gloomy and flowerless.

CULTIVATION OF SPECIMEN PLANTS.

In treating of the cultivation of the chrysanthemum in pots, I shall commence with the varieties that are most suitable for growing as specimen plants, such as are shown in 11-inch pots, a select list of which will be found at the end of this paper. The cuttings should be established in 3-inch pots by the middle of March; they are then stopped—that is to say, their points are pinched out. This induces them to throw out numerous side-shoots; this stopping or pinching back, as it is sometimes called, should be done with care and discretion, for as the object is to secure as many laterals to start with as possible, the extreme point of the shoot only should be taken off, for I have invariably found that treated thus they throw out more freely. About the first week in April the plants are ready for shifting into 6-inch pots, and I may remark here that *nothing is more injurious to chrysanthemums in the early stage of their growth than allowing their roots to be confined or cramped*; therefore, as soon as they have filled the pots, they should be immediately shifted to the next largest sized pots. The plants are kept in a cold pit until about the middle or end of May. The lights should be taken off on all favourable occasions, and the plants frequently syringed overhead to keep the foliage clean. As soon as I consider the weather sufficiently forward that there is no more probability of frost, I plunge them about half way up the pot in a sheltered but open piece of ground; and in order to prevent the worms making their way into the pots, I stand each upon a piece of slate, or perhaps what might do as well, a small pot inverted. They remain here until about the end of June, being stopped or pinched in the meantime when necessary; they are then shifted into their flowering pots, which measure 11 inches across inside, and are plunged as before, their shoots being secured with sticks, to prevent the wind breaking them. About the middle of July the plants are stopped for the last time (I may here observe that I never shift and stop at the same time). After this they require a little more attention in the training and regulating their shoots, which I keep tied down as near the rim of the pot as possible; this is more easily done now than when they have made their growth, on account of the brittleness of the wood when older. About the middle of September they are trained into something like the shape they are intended to be when in flower—that is, a round bush-like form—in order that the plants may be seen to equal advantage from any side; the one-sided plants so frequently seen at exhibitions being, in my opinion, most objectionable. As soon as the flower-buds make their appearance, I disbud, leaving only one to bloom on each shoot, as I consider quality of flower much better than quantity, more especially, as by a little judicious management I can get from 100

to 150 good flowers on each plant. I use manure-water liberally until the flowers show colour; indeed, this may be applied until the blooms are fully developed. I generally house them about the second week in October; but in this I am guided by the state of the weather, for they are better outside until the buds show colour, the foliage being improved by remaining in the open air as long as possible; it being a very important feature in a plant to have the leaves of a nice healthy green down to the very edge of the pot. When housed, I give all the air possible, when the state of the weather permits. I treat pompones in every respect the same as the large-flowering varieties, excepting that I do not disbud to the same extent.

CULTIVATION OF SPECIMEN FLOWERS.

The varieties most adapted for growing for the purpose of obtaining blooms of extraordinary size, or perfectly symmetrical shape, seldom make good specimen plants, being usually of a robust habit, consequently not so easily trained to form a compact head, and moreover do not bloom so freely. The magnificent stands of cut blooms to be seen at the metropolitan and local exhibitions show to what a state of perfection this flower can be brought by skilful management; indeed, by a careful selection they may be had in flower from October to the end of December. The general treatment of this class is the same as that directed for the growing of specimens, except that the shoots *should never be stopped or pinched back at all*. Most growers for exhibition put two plants in a 10-inch pot, and allow each plant to run up with a single stem. As they grow vigorously it will be found they will naturally throw out several shoots, or breaks, as they are called, but not more than three or four of the strongest of these are allowed to remain on one plant, and a single bud only is allowed to grow on each shoot; all but the the terminal ones should be carefully removed as soon as that can be done without injury. The whole strength of the plant is thus thrown into the three or four buds that are left for flowering.

CULTIVATION OF STANDARDS.

These are useful to break the monotony of a display, as their round heads on clear stems stand up above the dwarf trained plants, and have a very beautiful appearance. In case the reader is not familiar with the various forms in which the chrysanthemum is grown, I may say that a standard bears a near resemblance to a standard rose when the head is round and well furnished, and completely covered with flowers. The merest beginner may grow very pretty standards by following the directions I give, but it requires some practice to produce standards of first-class excellence, hence we do not often see at exhibitions good examples of this class. Some growers keep their standards several years, and the stems thereby become very stout and strong, and if well managed they have fine heads. But all the standards I have exhibited have been yearling plants—that is to say, raised from cuttings and grown to full dimensions in one season, after which they are destroyed. The reason I prefer yearling plants is that the old ones are not to be depended on; the old wood may die in the winter. The large-flowering kinds are not well adapted for standards, through a few, such as Little Harry for instance, might be managed successfully. As ornaments for the dinner-table are in demand, I would suggest to practical gardeners that standard pompones are admirably adapted for the purpose, as they do not interrupt the view across the dinner table, their heads being above the line of vision when the guests are seated, and they have a delightful appearance under artificial light. The way I treat them is similar to the others. I select good strong cuttings as early in the spring as possible, and when well established in small pots they are shifted into 48's, kept in the greenhouse, and staked the height I want the stem to grow, which is generally from two feet six inches to three feet. After they have attained that growth, they are then stopped in the same manner as I have before explained, the secret being to get as many breaks as possible from the first stopping to form the framework of the head; all side-shoots on the stem must be removed, but not the foliage. I invariably shift them for the last time about the middle of June; they are then plunged like the others, secured at the neck of the plant to prevent the wind breaking them, and liberally supplied with manure-water. The varieties best adapted for this purpose are the early and free-flowering sorts, so that they can be stopped a fortnight later than the others. As a long season of growth is desirable, the amateur may be led to take autumn cuttings for the formation of standards. I feel bound to say that experience has taught me that *spring cuttings are far preferable*, as they can be kept growing from the first, and they have such health and vigour that if properly cared for they make fine free heads, which plants from autumn cuttings will not always do.

REMARKS APPLICABLE TO EVERY SYSTEM OF CULTIVATION.

The young buds are apt to suffer much from the attacks of green-fly. Whenever this pest makes its appearance, the tips of the shoots should be dipped in tobacco-water, or what will perhaps

have a more permanent effect, be dusted over with dry snuff. The earwig is also a great enemy to the chrysanthemum, and should be destroyed by every available means; trapping with short lengths of bean-stalks, laid on the ground, and with small pots with a little moss in them inverted over the tops of the flower-sticks, are the best means.

The compost I use is one-half rich loam and one-half well-rotted dung, with a little leaf-mould, and a liberal sprinkling of sand added. The pots are drained with oyster-shells, and pounded oyster-shells may be advantageously mixed with the compost.

The manure-water used is made up in the following way: I have a large tank into which I put a sackful of soot and a barrow-load of cow or sheep's dung, or a half of each, it being filled with rain-water; the whole is stirred frequently for a few days, and then left to settle before being used.

Before drawing this short treatise to a close, I wish to impress on amateurs the necessity of avoiding exciting them with fire-heat, more especially when the buds are bursting, because it takes the colour out, and frequently makes a good incurved flower reflex. On the other hand, they must be protected from frost and storms, and hence a cool conservatory is the best of all places in which to flower them.

A SELECTION OF 50 LARGE-FLOWERING VARIETIES FOR SPECIMEN FLOWERS.

The best 25 marked thus *.

Abbé Passaglia, brassy amber; Alber tHelyer,* large rose purple, a noble flower; Alfred Salter, delicate pink; Antonelli, salmon orange; Beauty,* peach blush; Bernard Palissy,* bright orange; Beverley,* cream white; Cardinal Wiseman, crimson; Cherub,* golden amber; Dr. Brock, reddish orange; Duchess of Buckingham,* white, sulphur centre; Duchess of Wellington, delicate rose; Dupont de l'Eure, orange; Empress of India,* white, very large; Eve, sulphur yellow, incurved; General Bainbrigg,* dark orange amber; General Hardinge, Indian red; General Slade, red, tipped orange; Glohe, white; Golden Ball, bright orange, beautifully incurved, and fine form; Golden Dr. Brock,* bright golden yellow, beautifully incurved; Golden Eagle,* Indian red and gold; Golden Trilby,* (Forsyth's), fine yellow; Her Majesty, silvery blush; Iago, dark purple violet, incurved, good for pot culture; Imogene,* rose, shaded silver, incurved, fine show flower; Jardin des Plantes,* bright golden orange; King of Denmark,* bright rose lilac, incurved, fine show flower; Lady Carey,* large rose lilac, incurved, a beautiful show flower; Lady Hardinge,* delicate rose; Lady Slade, lilac and pink; Margaret Vatcher,* large rose, pink, incurved, and fine; Mr. Brullees,* large, Indian red, tipped gold, incurved, and fine; Mr. Wyness,* violet puce, incurved, a beautiful flower; Mrs. W. Holhorn, ivory white; Mrs. Kaines, blush, incurved, a fine late flowering variety; Pink Pearl, delicate pink, shaded silver, incurved, fine for specimens; Prince of Wales,* purple violet, beautifully incurved, a fine show flower; Princess Alexandra, lilac blush; Princess of Wales, white tinted rose; Queen of England,* blush; Raymond, golden fawn; Robert James,* orange cinnamon; Sam Weller,* Indian red, tipped gold, incurved, a fine show flower; St. Patrick, ruby red; Stafford, rosy purple; Stellaris globosa, carmine; The Glohe, bluish white; Themis, fine rose; Venns,* lilac peach, finely incurved, a beautiful show flower; Virgin Queen,* pure white, beautifully incurved, fine for specimens or cut blooms.

APPLE TREES FROM CUTTINGS.

How it comes that among plants of the same species, and even among seedlings reared from the same plant, some strike root much more freely when propagated, either by cuttings or layers, than others, is a physiological question which no botanical Fellow has yet undertaken to enlighten us upon. Certain it is, however, that among seedlings—say of *Rhododendron campanulatum*—which appear in all other respects exactly alike, some when laid down root readily within one year, while others scarcely furnish a sufficient supply of rootlets in two years to maintain life if then detached from the parent plant; and among zonal geraniums some grow freely by cuttings under the most careless treatment, while others can only be

tardily propagated even by the most judiciously applied skill. The same differences are more or less conspicuous among the varieties of all our cultivated plants, but in few of these are they more distinctly marked than in those of the wild and uncultivated apple. The name of *burr-knots* is very fittingly applied to the most easily rooting varieties of the apple, in consequence of their branches producing, more or less abundantly, hurr-like excrescences composed of thickly set rudimentary rootlets. These protruding rootlets may occasionally be seen, either solitary or few together, on the one-year-old shoots, but it is only on several years old branches and spurs that they assume those well-developed burr-knot forms, which have only to be cut from the parent tree with a branch attached, planted in ordinary garden soil, and that branch becomes a healthy small apple tree, not unfrequently bearing a fair crop of fruit the first summer after planting. Among crab or stock apples the burr-knots are represented by the Paradise, Doucin, and others, which assume the characteristic appearance when allowed to grow for some years, and which, although usually propagated by layers, may be grown by cuttings made from two or three year old shoots having no burr-knots, with almost as much facility as are willows and poplars. Among true apples, that excellent old variety, the Arbroath or Mother apple, has long been prominent as "the hurr-knot apple." And in pre-Reformation times, as well as since, it appears to have been chiefly propagated by cuttings in the orchards and gardens about Arbroath, St. Andrews, and other places where there are many old trees growing on their own roots, and not grafted, as other and neighbouring kinds have been, upon crab-stocks. Of more modern varieties the Manks Codlin, or Eve apple, as it was first called when simultaneously introduced from Ireland, about 1790, by Provost Ballantyne of Ayr and Mr. Wilson of Paisley, is one of the most prolific in burrs. The Keswick or White Codlin, as well as several other frequently cultivated kinds, also produces them freely. And among the nameless old varieties in the Carse of Gowrie orchards are five or six all designated "the burr-knots," although widely dissimilar in other respects.

The propagation of apples from burr-knot branches, although occasionally practised, is by no means so generally adopted by professional gardeners and orchardists as it deserves; for by this mode trees may be had in full bearing the first summer after planting, of all sizes, from 6-inch high spurs, to 3 or 4 feet high well-furnished plants, as thickly loaded with fruit as if they had been still retained on the parent trees. When so furnished, they make excellent pot-specimens in orchard-houses; and as a stock for dwarf, abundant-bearing apple trees of all kinds, the Manks Codlin will be found equal, if not superior, to either the Paradise or Doucin stocks. And as both it and the Keswick Codlin produce the finest fruit when the trees are young and vigorous, cutting propagation is an easy mode of keeping up a succession of these two abundant and constant bearing, indispensable, culinary, autumn ripening sorts.

In selecting burr-knot branches for planting, the first care requisite is to choose only true root-producing burrs, avoiding those excrescences which are caused by that worst of apple insect pests the American bug or woolly aphid; as well as those solid woody knobs which are occasionally produced on the branches of some old trees, neither of which will grow, while planting the first would only be at the risk of spreading and perpetuating an intolerable and destructive nuisance on neighbouring healthy trees. Having selected a branch with a proper burr or burrs near its base, it only requires to be pruned or trimmed into shape, leaving a few blossom buds, if they exist, to yield a supply of fruit the first season; then plant it in ordinary garden soil, mulched on the surface with well-decomposed dung, as is usual with newly-planted fruit trees, for the purpose of protecting them from the first summer's drought. If the soil is of a stiff or clayey nature, it will be necessary to surround the cutting with at least 6 inches of light sandy loam, which will be all the better if mixed with a third of peat and leaf-mould. The only further attention requisite is to watch the expanding flower-buds, and pick off any small caterpillars when they first appear, and apply water freely, but not too frequently, in the event of severe drought setting in. In the case of large branch cuttings, a coating of clay paint laid over their surfaces will be further serviceable in preventing the injurious effects of scorching sunshine upon the bark, before the young rootlets are able to furnish the requisite moisture supplies. When cuttings without burr-knots of free rooting kinds are planted, their success will be greatest if shaded northerly-exposed wall-borders are chosen for them.

These burr-knot formations are not confined to the apple alone, but also occasionally appear on Mayduke cherries and plums, especially when these are grown on moist shaded walls. In all cases where they exist the mode of propagation above described may be successfully resorted to. To amateurs and occupiers of small gardens, who find agreeable and healthy recreation in gardening, the rearing of apple trees from cuttings is especially recommended, as they will find its practice both interesting and profitable; for with what interest will such cuttings be watched and tended from the time of planting till that of fruit gathering in the succeeding autumn! And supposing that a redundancy of plants of any particular kind are so produced, they can always be usefully employed as stocks for grafting or budding other sorts upon, without the trouble and expense of applying to a sale nursery for wanted supplies, or the tediousness of waiting till they are reared from seed. "Waste not, want not," is an old and well-known axiom; therefore do not throw away hurr-knot branches in the pruning season, but rather carefully search for and plant them, resting assured that either for home use or presentation among friends they will be wanted before they attain overgrown or cumbrous sizes.—*The Farmer.*

DRYING PLANTS.—Twenty years ago, observes a correspondent in "Science Gossip," when botany was my hobby, I adopted a plan for drying my specimens which was both rapid and very effectual in preserving colours. I borrowed a tin dripping-pan from the cook, which was just the size of my sheets of blotting-paper. In this I laid the produce of the day's excursion between sheets of blotting-paper, in the usual way, and, when the pile was complete, I covered it over with a layer of common scouring-salt, half an inch thick, so that the tin dish appeared to be simply full of salt. I then placed it on the kitchen fender, or on the hob, or in the oven, if it were not too hot, and in three or four hours the whole batch of specimens was perfectly dried. It required a little care to take them out at the right moment, when they were baked just enough, and not too much; but this care being given, the success of the plan was perfect. Many specimens still in my herbarium bear witness to the superiority of such rapid drying over the old method.

TROPÆOLUM TRICOLORUM.

This lovely climber is seldom well grown, though it is a very easy subject. Everything is easy if you know how to do it:

It would be easy work to cleave the sky,
If we had wings, and knew how to fly;
Equally easy, too, to pierce the deep,
If we had gills and fins, and never needed sleep.

However, how to do it is the question, and as you admired my specimens the other day when "dropping in" to look round, I will fulfil my promise of a word or two as to their management.

I am never in a hurry to see my bulbs begin to grow. I never "s'art" them, as the saying is, but wait till the young shoots begin to push through the old soil of the pots they were flowered in the year before, and then I knock them out and repot. This occurs in January, February, or March, according to circumstances. Sometimes a bulb will take it into its head (or feet) to have a whole year's rest. It never troubles me—I let it rest. In repotting, I remove nearly all the old soil, but take care not to injure the young roots that are then pushing. The proper size pot to use is 32-size for a fair-sized root. There must be plenty of drainage crocks, nicely packed at the bottom of the pot, and over them a few lumps of tough fibry peat, as large as walnuts. The compost to fill up with should be equal parts nice fibrous peat, bright yellow loam, neither sandy nor clayey, and clean leaf-mould of the very best description. If this mixture is not granular and siliceous, add silver-sand about a sixth part of the whole, but the need for sand depends on the character of the other ingredients. Small bulbs must be potted with the points of the crown just peeping out of the soil, and in 48-size pots, but large bulbs in 32-size, and the bulb quite covered.

The best place for them is a top shelf in a sunny greenhouse, and as near the glass as possible. All tropæolums are fond of sun, and this plant is no exception; but take care it is not exposed to cutting winds or a damp and stagnant atmosphere. Supply moderately with water. When the stems are a foot high, put in the trellis; nothing so good as a balloon, I think, but every one to his taste, as you say in reviewing a toady catalogue. Now a very important matter after putting in the trellis is to place the pots inside larger ones, and fill the space between with moss. This keeps the roots moist, and somewhat makes amends for cramping them; besides, as the plants love sunshine, the roots are apt to be burnt unless protected in this way. Train as you go on; that is simple enough—a mere matter of careful fingering. When the flowers begin to open, take the plant to the conservatory, and shade slightly; when the bloom is over, give less and less water; and when the plants are really beginning to look shabby, return them to the shelf they came from, and dry them off for the winter. Do not disturb them till they grow again, and as S. H. sometimes says, "so on for ever."

R. E. P.

MARTYNIA FRAGRANS.

This charming annual is now rarely seen; indeed annuals, like perennials and everything else that ought to be prized by gardeners, are thrust out by the pressure of bedding plants. It is one of the very best plants for the adornment of the greenhouse when the bedding plants are turned out, and should be especially prized by those who grow Cockscombs, Globe Amaranthus, Balsams, and other beautiful soft-wooded and herbaceous plants, as the treatment they usually have suits it to a T. To grow it to perfection, treat it as a tender annual. Sow the seed now—that is to say, before February is out if possible, and if that is not possible, sow it the first opportunity in March. Sow a small pinch in a pot of light rich soil, and place on a good hotbed or other warm place to start it. Pot the plants singly as soon as they are large enough to handle; the stuff must be light and rich; there is no need to give a recipe, because any good compost that is about will suit it, but it must be good. Keep in a warm place till the plants are growing freely, and as soon as their pots are full of roots shift them to the next largest size, and as soon as weather permits place them in a cold frame. Treat them in the same way as Balsams, shifting them on till they are in 8-inch pots, and then shift no more. Of course they may be flowered in 5-inch pots, but they are not so fine as when grown on. Give plenty of water and air when the weather has become summery. No stopping is required, for the flower-stems are succeeded by laterals, and these soon flower, so that if in good soil and well treated the plants will make a height of three feet, and as much through, and be splendid objects in August and September. If planted out in the early part of June, it will flower well in a rich sheltered border. As to the flowers, they remotely resemble the Antirrhinum, but the throat is open, and the upper and lower portions are like huge jaws. The colour is chocolate-purple, with veins of yellow and rose in the throat. As its name implies, it is delightfully fragrant, and this quality adds immensely to its value.

E. K.

ON ACCLIMATISATION, AND THE EFFECTS OF THE LATE FROST.

"Have you any faith in acclimatization now?" asked my boy of me after returning home on the morning after a severe frost, which I had spent up to then in viewing the damage done to some plants of mine that had been out on hire in various conservatories. I answered, "That depends on circumstances. Why do you ask?" "Because some one writes in this gardening paper that 'the destruction by frost is fallacious.'" "Indeed! let me read the passage." And sure enough there it was: it also said, "There may be a gradual hardening of an exotic plant, though it never reaches the hardiness of a native." Oh, yes! I thought, after reading it, much after the way the man did who took it in his head to try if his poor horse could not do altogether without eating; and so the horse did for a certain time, but just as he got used to it he died. And so much about the same I have found it with plants. I have placed them, say, from a stove, very early in the spring, and they did pretty well in a warm corner of a greenhouse (but no draughts, mind you, or else away goes the top or young wood at once). Well, as the summer advances, and the temperature out of doors is quite as high as one can expect to get in a stove in the dead of winter, of course they do, and do well; and as the summer advances, and heat increases, they make their new wood, and nice sturdy growth it is. And so they continue so long as the temperature holds high; but so sure as winter approaches, they must have warmth; they will not do without it. I have tried plants of all sorts, but I never could get on without heat in the winter. I have lost many plants trying to do what Sam Slick would call *go in agin* natur, but I never could get an exotic to be gradually hardened. In fact, it is only in a winter like this that one can speak from experience what plants will really go through, for plants that I have always thought would stand anything in a conservatory are dead; and others, again, are but little the worse for the cold; and these last are the very ones you would have thought would have suffered. How is this? Simply because plants when first they are introduced are placed in a stove, if the place they come from sounds at all tropical (as was the case of the common *Aucuba* at first); they are there "coddled" up in heat until they get a hit plentiful, and distributed about. Some one, for instance, who admires the plant, has only a greenhouse to grow it in. He will try to grow it there, and succeed. Would this be called acclimatization? or would it not be better to say that now the plant has got in a temperature more like its native habitat, it of course flourishes accordingly? That I think would be nearer the truth.

Now I quite agree with naturalists that much may be done in the way of acclimatization as far as animals are concerned, and especially with birds for the blood of many animals remains at the same temperature, no matter if under the burning sun of Africa, or exposed to an arctic winter with the temperature 30° or 40° below zero. But with plants the case is vastly different, for many exotic plants contain an oil which becomes coagulated or frozen (in a certain sense) at a temperature of 40°. So in a case of this sort how are we to act when the plant that we have been hardening off, and has up to the present looked so well in a greenhouse, finds its flow of sap retarded and clogged at the first fall of temperature? Why, unless the plant is removed to warmer quarters, it will be sure to die! I have seen it so often; and I can assure your readers that all experiments of this kind have always ended in "grief" to the plant and disappointment to me, the only exception being with plants, as I said before, that should have been at the first placed in a cool house instead of a warm one. I will now give you a few instances of the various plants that have stood in a greenhouse this winter where the temperature has ranged from 35° in the very coldest weather to 60° in the warmest days. First, there is a large plant of *Dillenia speciosa*, that has always been thought a stove plant; it has up to now been growing well through the winter, and has not received the least damage from cold, whilst on the other side of it, and quite close, there is a *Rhopala* and *Acacia Drummondii*, both looking very brown and discoloured; in fact the tops of the *Rhopala* quite gone. Then, again, there is a plant of *Brexia chrysophylla*, side by side with *Sansevieria Javanica*, both stove plants, and in a warm part of the same greenhouse; the *Brexia* is dead half way down, and the *Sansevieria* looking very badly. Now the *Brexia* especially I have kept in a cool airy place since April last; by so doing it made very little growth, but all no good when the cold came. Again, I have had a large plant of *Aralia Sieboldii* not the least injured, although exposed to a frost one night of 8°. I must tell you that the frost was allowed to gradually thaw out, or the matter might have been different. In the same house stood several camellias, and these everywhere with me stood the best of any plants, even better than the *Aucuba*, for the leaves of the latter were browned, whilst the former received no injury. I will just mention, also, that in the same conservatory a nice plant of *Woodwardia radicans* is quite killed, whilst that graceful fern *Nephrolepis pectinata* received no injury. I mention these few facts for the benefit of your readers who have conservatories or greenhouses that are imperfectly heated, that they may know what plants will stand the cold and what will not; and I can assure them I have paid for learning to the cost of many plants, and I wish none of them in this instance "to go and do likewise;" and I think many of them will say with me, whilst looking over the sad havoc that the frost has done this winter, "Is it possible that any one can say in the face of facts that 'the destruction by frost is fallacious'?"

JOHN BURLEY, F.R.H.S., &c.

Bayswater, W.

MOST PERFECT PLANTS.—Those plants are most perfect in which the organs discharging different functions are most distinct both in position and structure. The thalloid fronds (of Cactaceæ) and the hypoblastoid embryos of Endogens indicate a lower degree of organization. Plants which have the stamens and pistils either naked or in the axil of an unmodified leaf (*Naias*, *Hippuria*, *Callitriche*) are inferior to those whose flowers are never complicated. Diclinal flowers are lower in position than those which are hermaphrodite; ternary verticils lower than quinary, spirally arranged floral organs lower than those which are verticillate, polypetalous flowers lower than gamopetalous, apocarpous ovaries lower than syncarpous, atropous ovules lower than those which are inverted, homogeneous embryos lower than those which are fully developed. Trees and shrubs are more common among imperfect plants. In the lower orders flowers are very numerous, in the higher the number of seeds produced by each flower is very great. Yellow and green colours in the flowers of the lowest rank are changed into red or white in those of a higher order, and in the highest plants the colour of the flower is generally blue.—J. G. Agardh, in *Theoria Systematis Plantarum*.

Calendar.

WORK FOR WEEK COMMENCING FEBRUARY 23.

Kitchen Garden and Frame Ground.

OUTDOOR WORK may be carried on most advantageously while this weather lasts, and until stopped by return of frost or wet. Land ridged up to the frost will get mellow and fertile. As ample notes on outdoor work have been given during the past few weeks, reference may be made to them, and arrears must be made good by extra activity. Winter may linger with us far into March, which will perhaps be less injurious in the end than it appears, for late springs are usually good ones. Therefore those who are now complaining may hereafter have cause for rejoicing. A little more patience, and spring will burst on us suddenly, and startle us as of old with its wealth of song and beauty, and the kindly and quickening glances of the sun fast ascending towards the northern regions of the heavens.

EDIBLE AND ORNAMENTAL GOURDS.—Gourds are now grown in collections, and add very much to the interest of the kitchen garden, while a few of the smaller-growing kinds are invaluable for decorating trellises, arbours, summer-houses, &c. The London public have had very fair examples lately of the attractiveness of gourds as subjects for exhibition. Mr. Young, gardener to R. Barelay, Esq., West Hill, Highgate, has exhibited 1,000 varieties, covering about 60 feet run of table space, and comprising specimens varying in size from that of a "big drum" to a nutmeg, and of all colours and shapes. 1,000 varieties have also been shown by Mr. Blundell, of Burlesdon, Southampton, who was the original introducer of the cattle melon. Here, again, were samples of all sizes, many of them gorgeously coloured, and not only curious, but wonderful in outline. In each of these instances the seeds had been supplied by Messrs. Barr and Sugden, in the regular way of trade, a fact which affords some idea of the popularity gourds have acquired among amateur cultivators. Many persons who see these collections, and who know that to grow them is scarcely more difficult than to grow a bunch of turnips, are nevertheless deterred from engaging in so profitable and amusing an undertaking by the general fear of poison which prevails. There is no proper ground for any such fear; nearly all the ornamental gourds in cultivation are edible, and if ever a question should arise, the flavour of the gourd will determine it in an instant. All pernicious examples of *cucumis* have an obnoxious taste, and the quality of a gourd may be ascertained without cutting it, by merely taking a small slice from the stalk and masticating it. If that is nauseously bitter, it would not be wise to eat the gourd. But even this test is unnecessary, because poisonous gourds are too disgusting in flavour for any human being to swallow enough to do injury. As to the use of gourds, it is well known that any of them may be boiled when young in the same way as the common vegetable-marrows, and make a most acceptable accompaniment to roast meat. The common pumpkin of the cottage gardens, cut when as large as a good-sized turnip and boiled, is quite equal to the best of the marrows. But it is not so well known that the green tops nipped off the vines (three inches long at the utmost) make the most elegant and delicious dish of greens ever cooked. People grow spinach beet, which never cooks a good colour, because during very hot weather spinach is always stringy and seedy. It would be much better to plant out a few common pumpkins on purpose to supply green tops, for when kept nipped they throw out new shoots abundantly, and pay as well for greens as for fruit, but no one should expect both in large quantity. If the seeds are sown in the open ground on small hillocks on the 1st of May, a good crop of either fruit or tops may be expected; in fact, all the gourds may be grown by this simple method. But it is much better to sow on a gentle hot-bed about the 10th of March, and get all the plants potted in good time, and plant out early in May on beds prepared for the purpose, and raised a little above the general level, both to catch the earliest rays of the sun, and to throw off excess of water during heavy rains.

Flower Garden.

GARDEN PLANTS IN FLOWER.—*Aubrietia deltoidea*, and others; *Systirinchium grandiflorum*, *Hepatica angulosa*, *Saxifraga cordifolia*, *Adonis vernalis*, *Pulmonaria rosea*, *Draba azoides*, *Viola odorata*, *Viola collina*, *Fumaria cava*, *Ranunculus ficaria*, *Potentilla fragaria*, *Anemone pulsatilla*, *Snowdrops*, *Crocuses*, various; *Narcissus nanus*.—*Frame*: *Dielysra spectabilis*, *Cyclamen Europeum*, *Cyclamen comn*, *Bulbocodium vernum*, *Erica herbacea* and *codonodes*, *Russian* and *Neapolitan Violets*, *Leucocium vernum*, *Erythronium dens canis*; various *Narciss*, *Jonquil*, and other bulbs.

BEDDING PLANTS may be multiplied to any extent with the help of a good hotbed, and the necessary plants to begin with. However ingenious and useful may be such things as *Waltonian*, *Bijou*, *Maling*, and other plant cases, the amateur who has any ambition to grow plants in earnest, and especially if anxious to make a good display of bedding plants, ought to master all the small difficulties of making and managing a hotbed. Supposing the means for propagating to be at hand, a few hints of a general kind on the essentials of success may be of some service. Usually it is a waste of time and trouble for amateurs to attempt to root cuttings which consist of old wood. Suppose, for instance, a verbenas in a pot saved from last year. It consists probably of a few long woody shoots terminating in clusters of leaves, and a few short and rather hard side-shoots clothed with leaves. It may be in perfect health, and one of the finest varieties known, but in its present state it is useless for propagating. If I cut some portion of one of the old, hard, woody stems, it is simply a waste of so much wood, for it will sooner perish than throw out roots. But if this same verbenas is placed in a genial and rather moist atmosphere, say in a frame placed upon a dung-bed in a nice sweet condition, or if it is placed in the coolest part of the stove, it will soon throw out a number of small shoots. When these shoots are an inch long, they may be slipped off with what is termed a "heel"—that is, removed by separating them at the point where they are articulated to the stem, or they may be cut through with a sharp knife. Those soft shoots only require to have one or two leaves removed, so as to make a bare space sufficient to allow of them being planted firmly, and they are ready for use. The simplest and surest way of dealing with them is to dibble them firmly into pans filled with silver-sand, placing them close together, and then place the pans on the hotbed, and shut them up close. If the heat is about 60°, and never exceeds 70°, every one of those little cuttings will make roots.

To help them along, the first essential is to look at them pretty often. No plant, however small or large, will prosper without being looked at by its owner. When you look, observe if the leaves of the cuttings are dry; if they are, sprinkle them with tepid water. If the heat is steady, they will bear to be quite moist, and in fact may be so wet that there is a film of water on the top of the sand. But this is not advisable; a moderate degree of moisture suffices, and as for air they scarcely need it until they begin to grow. When the points of the cuttings assume a lively green hue, you may be sure they have formed their roots and are about to grow. Let them grow a little before disturbing them, and then remove them carefully so as not to injure the delicate roots, and put them into what are called thumb-pots singly, or pot them three or four together in six-inch pots, using for the purpose fine, light, rich soil. A mixture of equal parts mellow loam, very old hotbed manure, leaf-mould, and silver-sand, well broken up together, will do admirably for nearly every kind of greenhouse plant at the first potting—certainly for all kinds of bedders. The plan thus adopted for propagating *Verbenas* may be followed with *Fuchsias*, *Petunias*, *Heliotropes*, *Ageratum*, *Alyssum*—in fact everything, if a few modifications are allowed for the varying habits of the plants to be dealt with. Beginners will find that young shoots just getting firm will root more certainly than those in a very soft state. It will next be observed that plump and strong shoots of *Geraniums* answer better than mere inch lengths of new growth, and that *Geranium* cuttings require less water than most other cuttings. It will also be noticed that a sudden outbreak of sunshine causes many of the pans of cuttings to look very odd, and that in a batch of cuttings suddenly visited by his solar majesty, many never recover from his fervid glances. Practical gardeners make very short work with sunshine; they just lay over their cuttings a newspaper; but the amateur will prefer to tack to the roof a breadth of tiffany or some other shading, to prevent the roasting of his whitebait which he has intended for a stew. There is one result that every beginner must expect and that is an outbreak of mildew. With experienced cultivators, mildew is almost unknown; but your novice seems to attract it to himself by some unenviable charm. Mildew implies that the heat is too little and the damp too much. If the temperature can be raised, let it be so; at the same time give a little air cautiously, and abstain from giving water until it is absolutely necessary to prevent the cuttings flagging, which they should never do. Warmth and dryness are the best cures for mildew; but if they do not appear to be sufficient, dust the affected leaves with flowers of sulphur. An instrument called the *Boite à Houppes* is the best contrivance known for sulphur dusting; it may be obtained of Messrs. Burgess and Key, of Newgate Street, for half-a-crown. Some growers use a pepper-box, and some a box with a bit of muslin tied over it. Another good plan in case if mildew is to sprinkle dry peat-dust or dry silver-sand amongst the cuttings, so as to form a new surface-soil amongst them. But the grand thing is to keep the heat steady, and accidents will be few and far between.

Fruit Garden and Orchard House.

FRUITS IN SEASON.—*Apples*: *Alfriston*, K; *Asbmead's Kernel*, D; *Barcelona Pearmain*, D; *Beauchampwell*, D; *Bedfordshire Foundling*, K; *Bess Pool*, K; *Borsdorfer*, D; *Boston Russett*, D; *Brabant Bellefleur*, K D; *Braddick's Nonpareil*, D; *Bringewood Pippin*, D; *Brownlee's Russet*, K D; *White Calville*, K; *Claygate Pearmain*, D; *Cockle Pippin*, D; *Coe's Golden Drop*, D; *Cornish Gilliflower*, D; *Court Penduplat*, D; *Dumelow's Seedling*, K; *Dutch Mignonne*, K D; *Federal Pearmain*, D; *Forman's Crow*, D; *French Crab*, K D; *Gooseberry Pippin*, K; *Hambleton deux ans*, K D; *Hanwell Souring*, K; *Holbert's Victoria*, D; *Hubbard's Pearmain*, D; *Lamb Abbey Pearmain*, D; *Lemon Pippin*, K D; *Mannington's Pearmain*, D; *Margil*, D; *Minchall Crah*, K; *Minier's Dumpling*, K; *Morris's Nonpareil Russet*, D; *Newton Pippin*, D; *Nonpareil*, D; *Norfolk Beefing*, K; *Northern Greening*, K; *Northern Spy*, D; *Ord's*, D; *Pearson's Plute*, D; *Pennington's*, D; *Pile's Russet*, D; *Pinner Seedling*, D; *Reinette Blanche d'Espagne*, K D; *Reinette du Canada*, K D; *Reinette Grise*, D; *Reinette Van Mons*, D; *Rhode Island Greening*, K D; *Ribston Pippin*, D; *Ross Nonpareil*, D; *Royal Pearmain*, K D; *Royal Russett*, K; *Scarlet Nonpareil*, D; *Sereveton Golden Pippin*, D; *Spring Ribston*, D; *Stamford Pippin*, D K; *Striped Beefing*, K; *Sturmer Pippin*, D; *Sweeny Nonpareil*, K D; *Tulip*, D; *Wheeler's Russet*, *Winter Colmar*, K; *Winter Strawberry*, K D; *Winter Quoining*, K D; *Wyken Pippin*, D.

Pears.—*D'Avril*, *Bergamotte Espere*, *Buerré Bretonneau*, *Buerré Gris d'Hiver*, *Buerré de Rance*, *Bezi de Bretagne*, *Bezi de Caissoy*, *Bezi Goubault*, *Cassante de Mars*, *Chaumontel*, *Colmar*, *Easter Bergamot*, *Easter Buerré*, *Elisa d'Heyst*, *Fortunee*, K; *Groom's Princess Royal*, *Jean de Witte*, *Joséphine de Malines*, *Leon le Clerc de Laval*, K; *March Bergamot*, *Morel*, *Ne plus Meuris*, *Pengthley*, *Prince Albert*, *Rameau*, *Spanish Bon Chrétien*, K; *Uvedale's St. Germain*, K; *Van de Weyer*, *Bates*, *Verulam*, K; *Winter France Real*, K. The above lists of apples and pears comprise good varieties, or varieties good for the season, that may be in condition in the month of March. It would be rendering a most practical service to pomology, and would therefore be mutually beneficial, if our fruit-growing readers would send us a few particulars of their present fruit stores, giving the names of such kinds as are still good, and such also as were in use last month.

Grapes.—Of last year's crops there may yet be good bunches of *Black St. Peter's*, *Barbarossa*, *Black Hamburg*, and *Lady Downe's Seedling*. Where grapes are forced, supplies may soon be expected of such varieties as *Chasselas Musqué*, *Muscat Hamburg*, *Purple Constantine*, *Red Frontignan*, and *White Frontignan*.

WALL GRAPES.—A moderately fertile sandy loam will be found the best for the growth of grape vines out of doors. As rules are easily remembered, a rule is offered here, the colder the position, the poorer must the soil be. Rich soils and fat manures are not at all desirable for the growth of outdoor grapes; and in a cold, wet summer, the vines on the poorest and driest borders will do better than those on moist, well-manured borders. It must not be supposed, however, that the grape vine can live upon nothing; indeed, it would be a folly to plant grape vines on a worn-out, sour, or pasty loam, on which nothing else could be grown satisfactorily. Should it be necessary to prepare a border for vines, two feet depth of prepared earth will be sufficient, and this should rest on a dry bottom; if on a stratum of stones or bricks all the better; but this is not needful. It is needful, however, that the border should be perfectly drained, either naturally or artificially; if water stagnates upon it all the winter long, the vines will become afflicted with disease, and to expect grapes from them will be absurd. Turfy loam, sharp sand, half-inch bones, and clean build-

ing rubbish are the best of all materials wherewith to make a border for out-door vines. If the mixture consists of one-half loam, and the remaining half equal parts of the other materials, it will answer admirably. If the loam is not turfy or fibrous, or is suspected of being poor, some good manure may be added; say in the same proportion as the sand, bones, and building rubbish. "Clean" building rubbish consists of nodules of brick, old mortar, flint, chalk, and plaster. If laths, tin kettles, old iron, and scraps of sheet lead are mixed with it, it is not fit for any horticultural purpose, except it might be for the foundation of a walk. Generally speaking, however, the common soil of the garden can be made suitable for vines at a small expenditure of labour and money. One reason why wall grapes are not much thought of, is that, generally speaking, the worst kind of grapes that can be discovered are grown upon them. The following will produce plenty of fine fruit, and ripen it well, unless the season is very cold and wet, on any good wall, except in places that are absolutely bleak and notoriously unsuitable:—

Grapes for South and West Walls.—Chasselas Vibert, large, golden amber, juicy and rich. Royal Muscadine, large, greyish green or pale amber, juicy and sweet, a first-class grape to grow for light wines. Prolific Sweet-water, large, pale amber, flesh juicy and sweet. Far surpasses the Dutch Sweetwater. Cambridge Botanic Garden, large, oval, brownish black, with fine bluish bloom, flesh firm, sweet, and highly flavoured. Esperione, large, round, jet black, covered with blue bloom, flesh very juicy, sweet, and rich, bears abundantly, and generally considered the best of all wall grapes. White Romain, small oval, rich amber, transparent, very sweet and rich, bears abundantly. Miller's Burgundy, an excellent out-door black grape, which may be distinguished from all other varieties by the hoariness of its leaves.

Grapes for very favourable South Walls.—Chasselas Musqué, round, greenish white, or pale amber, flesh firm, rich, sugary; a most delicious grape; in fact, one of the finest dessert grapes known. Early Smyrna Frontignan, medium size, round, bright amber, very juicy and delicious. A very early grape, and always ripens on a good wall. Muscat St. Laurent, small, oval, pale amber, juicy, with a high muscat flavour. Early and reliable. Muscat Lierval, medium, round, deep purple, with light bloom, flesh rich and sugary, with trace of muscat flavour. An excellent early grape, but rather shy in setting. Black Hamburg needs no description. It is the most useful variety known; it requires a hot wall in the south and west of England, but is no use as a wall grape in eastern and northern districts.

Greenhouse and Conservatory.

GREENHOUSE PLANTS IN FLOWER.—A great many hard-wooded plants are now coming into bloom, such as *Coborozema flava*, scandens, varia, and spectabilis; *Acacia armata*, spectabilis, rotundifolia, dealbata; *Boronia pinnata*, latifolia; *Hovea purpurea*; *Callistemon rigidum*, speciosum, semperflorens; *Bossia ovata*, tenuicaulis, cordifolia; double-flowering Plum, Peach, and Cherry; *Camellias*, *Azaleas*, *Hibbertia flexuosa*, *Cytisus* of various kinds; also *Primulas*, *Cinerarias*, *Cyclamens*, *Echeveria secunda*, and *Pelargoniums* Gauntlet, Crimson King, &c.

ERICAS IN FLOWER.—*Aristata major*, *aristata vittata*, *acuta*, *humana*, *pomifera*, *viscaria*, *persoluta alba*, *mandula*, *vernalis*, *acuminata*, *fragens*, *atrorubens*, *Blandfordiana*, *cerinthoides*, *Bonplandiana*, *purpurea*, *nigrita*, *vestita*, *lacticolor*, *pendens*.

CALCEOLARIAS of the shrubby kinds are now growing freely. All autumn-struck cuttings should be potted into separate pots without delay, or a weak growth and a late bloom will result. Herbaceous *Calceolarias* must never get pot-bound till they are in their blooming pots, or they will throw up their blooms prematurely. If these are in a dry atmosphere now, they will soon be smothered with green fly and red spider. Prevention is better than cure, so keep them moist and growing, and if any vermin, smoke at once, and make an end of them.

HYACINTHS.—A complaint made by amateurs is that the flower-spikes of *Hyacinths* do not rise freely, and the flowers open confusedly close down to the bulb, and look ridiculous. Others write to say that in the majority of cases *Hyacinths* throw two and three spikes instead of one. Dumpiness has been the subject of many proposals, and the remedy most in fashion is the application of a paper funnel, a sort of sugar-paper with the pointed end cut off to draw the spike up to its proper length. This is a foolish practice, in spite of its having been advocated by men who justly hold a high position in the horticultural world. If the paper caps once get well soaked with water, which they are likely to do, they may subside in a shapeless and sticky heap about the flower-spike, and cause the rotting of some of the pipes, and the discolourization of all. If the spikes can be "drawn" by excluding from them all side-light, there can be nothing so simple and handy as an empty flower-pot inverted over the plant, the leaves being carefully brought together so as not to be broken by the edge of the pot. But query, does the cap, whether paper or flower-pot, assist in the development of a fine spike? Such a result was never heard of, and assuredly never will be heard of, for the simple reason that dumpiness is the result of weakness, and a nightcap is known to be no cure for debility. All these dumpy *Hyacinths*, and all those that show canker on the spike, and that shed their buds instead of expanding them, are weak in the roots. If we turn one of them out, and shake away the soil, we shall find that the bulb has either made no roots at all, or only a few poor weak ones that seem quite unable to push through the soil, and find nourishment for the leaves and flowers. When the spikes of such begin to show colour, it is too late to do anything with them, but if taken in time, dumpiness may to some extent be prevented. Our date for opening the store of plunged *Hyacinths* in pots is the 1st of January. From the time of potting until that day comes, they are out of doors, packed close together, and covered with six inches of cocoa-nut fibre refuse. When taken out on the 1st of January, they are generally so far advanced as to have grown two inches above the bulb, and they are variously disposed of—some to the forcing-pit, others to cold frames, &c., &c., according to the existing and anticipated demand for flowers. Now it is when first removed from the plunge bed that the cultivator must determine which are likely to attain to their proper growth, and which, if left without special help, will be dumpy. Those that have the leaves and spikes closely packed together, and in the form of a pointed cone, may be considered the most promising. They have formed plenty of good roots, and intend to open their leaves freely, and send up their spikes in a dignified manner. But all those which exhibit a small club-like mass of flower-buds, with small leaves already parted from the centre and diverging from it, are candidates for dumpiness. The bulb is endeavouring to produce its leaves and

flowers without the aid of roots, and it cannot send up a free green growth through deficiency of sap. All these should be placed on a very gentle hotbed, and be covered with at least four inches depth of some clean material, such as cocoa-nut fibre refuse, fine soil—anything that will lie close about them, and keep spikes and leaves in the dark. The majority will make root in abundance, after a fortnight's sojourn in the hotbed, and when taken out the spikes will be considerably advanced, and promising well. The best way to flower these will be on the same bed, fully exposing them to light, that leaves and flowers may have their proper colour, and giving air (very little at first) by degrees, to render them comparatively hardy. A heat of 60° is quite sufficient for the cure of dumpiness; if put into a fierce heat, the bulb will melt into a jelly. The exclusion of daylight while the first process of rooting takes place is most important.

Stove and Orchid House.

ORCHIDS IN FLOWER.—*Dendrobium nobile*, *D. macrophyllum giganteum*, *D. pulchellum purpureum*, *D. densiflorum*, *D. Pierardii*, *D. aggregatum majus*, *D. Cambridgeanum*, *Pbajus Wallichii*, *Trichopilia navis*, *Blattia patula*, *Lycaste cruentata*, *Cattleya amethystoglossa*, *C. Mossiae*, *C. Mossiae aurantiaca*, *C. Mossiae superba*, *Chysis aurea*, *Cycnoches pentadactylon*, *Pbalaenopsis amabilis*, *P. grandiflora*, *P. rosea*, *Cymbidium eberneum*, *Cyrtopidium biflora*, *C. caudatum*, *C. caudatum roseum*, *C. hirsutissimum*, *Vanda cristata*, *Lpidendrum crassifolium*, *E. aurantiacum*, *E. Hanburyanum*, *Aganisia pulchella*, *Bolbophyllum saltatorum*.

STOVE.—Such plants as have done blooming must be cut back, and have encouragement to break before repotting them. Those which especially need attention now are *Euphorbia Jacquiniiflora*, *Eranthemum pulchellum*, *Poinsettia pulcherrima*, *Geissomeria longiflora*, *Gesnera lateritia*, *Justicia coccinea* and *calytricha*, *Linum trigynum*, *Gardenia florida simplicis*, *G. Thunbergii*, &c. Many orchids are now sending up their flower-spikes, and must have sufficient heat and moisture for their full development. Orchids needing a shift should have it just as they begin to grow. The orchid house should be carefully managed now as respects temperature; generally speaking, the thermometer may safely range from 55° to 75°, and the extreme maximum for these sunny days should be 80°. Be careful to exclude the frosty air, or spot will follow, but give air as much as possible, having regard to safety, while this weather continues. Another matter to be careful about is to prevent lodgments of water in the axils of the leaves. No doubt in their native climes the channels of the leaves are irrigating machines to the plants, but the artificial circumstances we place them in do not admit of allowing them to serve such a use.

FIRES have been kept up lately, and many things have got dry. We have just looked at a lot of seedling ferns in pots on a shelf close over a hot-water pipe, and found them as dry as dust; probably some of our readers may be in the same predicament. The remedy is at any one's fingers' ends, but if not used quickly the dried-up plants will die, and there is no remedy for death, though for mere dryness any one can guess at it. Heaths and New Holland plants generally will be likely to suffer by fire-heat just now, especially as owing to the recent mild weather many of them are in a rather soft state; keep down the day heat by giving plenty of air, for houses kept close now soon get up to 80° or higher. And keep down the night heat so that it just suffices to make all safe against frost, which is most severe generally from 4 a.m. to 6 a.m., when the fire is out or at its worst.

Forcing Pit.

CHERRIES in the forcing-house will probably have black or green fly. Do not be content to pass through the house and see them looking apparently well. The black fly will sometimes get a firm hold before it is suspected, and when at last, by the curling of leaves and other signs, the cultivator discovers the enemy, it is too late to save the crop. A dry heat will always fill cherry trees with fly, therefore syringe freely except when they are in bloom, and give air in plenty at all reasonable and seasonable opportunities. Hand-picking is the only way to deal with caterpillars; every curled leaf should be examined, and the worm removed and killed without injury to the leaf. Some careless people crush worm and leaf together, which is certainly a great saving of time over the more careful method.

CUCUMBERS.—Where the growth proceeds freely, woodlice will proceed freely too. Make them proceed more freely than they intended by watering round next the woodwork with boiling water. If this is done occasionally in the middle of the day, it will prove an effectual settler. Plants fruiting to be kept well fed, and the temperature steady. If any need for linings, let there be no delay in applying them, for if the roots get a few degrees too cold to sustain the demands upon them the fruit will be lost. Always water the roots with warm water; the simplest way of obtaining it is to keep a shallow can or pan in the frame, and fill it as needed. If any sun-heat, shut up at 80° or 85°.

PEACHES in the early house will now need training and disbudding. Secure wood where wanted, and suppress that which is superfluous. Keep rather dry at the root until stoning is completed, and then commence to thin the crop by degrees.

PINES.—If dealt with as advised a few weeks back, the succession plants will now be in the mood to grow freely. Fruiting plants will require a liberal top-heat and plenty of water, and as much air as can be given safely to assist the colouring.

VINES that are in a poor condition should be allowed to carry nearly all the wood they make, or at least only those laterals should be removed that have no chance of a due share of daylight. Cultivators often forget that when a tree is allowed to make a free head it will at the same time make a free root; and, on the other hand, if we check the growth above ground by pinning and pinching, the growth below ground will be equally retarded and restrained. Vines with swelling bunches must have every needful care, and especially as to the thinning of the bunches—a matter in which every grape-grower should seek to become dexterous. For these the day heat may be 70° to 85°, night 50° to 55°.

STRAWBERRIES swelling their fruit must be well fed, either by renewing the dung in which the pots are plunged, or by means of liquid manure. Strawberries showing colour now will acquire an admirable flavour with the aid of sunshine, and the more so if they have plenty of air. Keep them as near the glass as possible, and take care that they are well fed. If they get quite dry at the root, the crop will be lost.

A SELECTION OF FUCHSIAS.

As I have been a most successful exhibitor of the Fuchsia, and had the honour of carrying off the first prize for a collection of six plants at the Great International Exhibition, I may presume to name a few of the best varieties, both for purposes of exhibition and decoration; and these, if well managed, will surprise even experienced growers.

SCARLET FUCHSIAS WITH SINGLE DARK COROLLA.

Light Heart.—This has a nearly black corolla, changing to a violet-plum colour when fully expanded; foliage medium size; habit short-jointed; the best in habit of all the black corolla varieties. A very good and distinct sort for exhibition.

War Eagle.—Large violet corolla shaded with crimson; a bold flower, of great substance; free flowerer; habit good; fine exhibition variety. One of the best.

Lizzie Hexham.—This is a beautiful telling dark variety; tube and sepals brilliant scarlet, properly reflexed, large rich dark purple corolla; good grower and fine habit. This is certainly one of the finest fuchsias ever sent out.

Harry George Henderson.—This is a remarkable and very effective variety, with broad bright coral-scarlet sepals, well reflexed, and very large round rich plum-violet red corolla; of great substance, and certainly one of the finest fuchsias ever seen; good habit, and a strong grower.

Aurora.—The corolla beautifully expanded, well reflexed; good grower; fine for exhibition.

Charming.—A very fine flower; the corolla distinct from any other. A good grower; one of the best.

La Favorita.—The shape of this bloom comes very near to perfection, and the plant will no doubt become what its name denotes. One of the best.

Lord Elcho.—A very fine bold flower, and if well grown, one of the very best for exhibition.

In addition to these, which are fine sorts for exhibition, the following are valuable for purposes of decoration: Enoch Arden, a free-blooming variety, with the largest corolla and the most substance of any fuchsia at present in cultivation; Conquest, rather dwarf, a beautiful shaped flower, one of the best ever sent out; Land of Plenty, an elegant and effective variety, almost perfection in shape, requires good cultivation, but if well grown is a perfect model; Victor Emmanuel, the best, with yellow-tinted foliage, very attractive, distinct, and should be in every collection; Fame, good habit, one of the best; The Lord Warden, a very fine flower, the corolla perfectly distinct in colour from any other fuchsia; Bæceus, a splendid little fuchsia, one of the most graceful-habited varieties, and one of the best for exhibition or small pots; Exhibitor, one of the finest reflexed fuchsias, a strong grower, of good habit; La Traviata, a gem, and one of the best dwarf fuchsias for small pots; Lucrezia Borgia, a fine large flower, much the best variety with striped corolla.

SCARLET FUCHSIAS WITH SINGLE ROSE OR LAVENDER-COLOURED COROLLA.

Roderick Dhu.—Corolla blue, very large, opening out à-la-Crinoline; habit beautiful, and a free bloomer. The flowers being large, and of a fine colour, combined with a nice bushy habit, this is one of the finest varieties for exhibition purposes.

Father Ignatius.—Corolla beautifully cup-shaped, indigo blue, sometimes striped with rose, mostly on the first lot of blooms that open; foliage small, habit bushy, short jointed; very free bloomer. The corolla has the finest outline of any fuchsia extant. From its free-blooming habit and fine form, it is one of the finest for exhibition.

Consolation.—Sepals light carmine, bluish lavender corolla, changing to a plum colour when fully open; habit good, very free bloomer, and one of the best for any purpose.

Northern Light.—This is a fine bold flower, the corolla is of a bluish-purple colour; a good grower and habit, and fine for exhibition.

Sunshine.—This is a beautiful variety; good habit, and the colour of the bloom very attractive. One of the best.

Beauty.—A beautiful exhibition variety, with broad bright carmine-scarlet sepals, gracefully recurved; the corolla pure lavender colour, cup-shaped, of a model outline; growth free and vigorous, adapted for pyramid or bush specimens. This beautiful variety is one of the best.

For decoration the following sorts may be added: Constellation, a remarkable variety, and very attractive for the decoration of the greenhouse; Emblematic, a fine kind, very large and attractive, and decidedly one of the best, good and free; Don Giovanni, close dwarf habit and beautiful corolla, one of the best for small pots; Finsbury Volunteer, a good showy kind; Rifleman, a little gem, dwarf, of good habit, and a most profuse bloomer, one of the best for small pots, or the decoration of the dinner-table, young plants will bloom all the winter; Ben-e-Gloe, distinct and very dwarf, one of the prettiest little fuchsias ever seen.

WHITE FUCHSIAS WITH SINGLE PURPLE COROLLA.

Prince Alfred.—This is a splendid fuchsia, a most profuse bloomer, a strong grower, and one of the very best for any purpose. It must be well stopped when young.

Lady Haytesbury.—This is a first-class new fuchsia, decidedly one of the best for decoration; blooms and foliage good; fine habit.

WHITE FUCHSIAS WITH SINGLE SCARLET OR PINK COROLLA.

Rose of Denmark.—Corolla light pink, margined with rose; habit rather strong, but blooms very freely at the points; being distinct from the other light varieties, this should be in every collection, either for exhibition or conservatory.

Lucy Mills.—Corolla light pink edged with bright rose; after the style of Marginata in habit and bloom; the blooms being larger and brighter in colour, it is an improvement on that variety. A good white for exhibition.

Catherine Parr.—White tube and sepals, the latter well reflexed, great substance, corolla cup-shaped, of a rich scarlet tinted rose, a great improvement on Reine Blanche and all of that class; good grower and a fine habit. One of the best for exhibition; a model variety.

Arabella.—White tube and sepals, very large and long, reflexed, corolla rich rosy-pink, very fine flower, good grower and habit; a most profuse bloomer. This is a magnificent variety; for decoration one of the best.

Agnes.—Strong grower, great substance in the flower, free bloomer. One of the best for exhibition.

Mlle. Tiotjens.—This is a very nice fuchsia indeed, and certainly one of the best; it is of graceful habit, and an abundant bloomer; fine for exhibition.

Minnie Banks.—One of the best out; splendid corolla, quite distinct from any other, and one of the best for exhibition.

To these, for decorative use, may be added,—Bianca Marginata, one of the best of its class, large, the corolla very fine; Il Trovatore, large and of splendid shape, but the corolla is apt to become deficient; Merry Maid, a splendid fuchsia, one of the prettiest out, fine for small pots, or the decoration of the dinner-table.

SCARLET FUCHSIAS WITH SINGLE WHITE COROLLA.

Conspicua.—This is a first-class show kind, a good bloomer; the habit is very much improved when the plant is two or three years old. Best for exhibition.

Puritani.—This is by far the best habit of any of the white corollas out; one of the best for small pots, or for the decoration of the dinner-table.

Mrs. Gladstone.—The habit, and its fine large bold flowers and perfect shape place this beyond all others in its class. Tube and sepals bright waxy scarlet, the latter very broad and reflexed, equal to the well-known Guiding Star; the corolla pure white with a beautiful scarlet feather, and bell-shaped; a most abundant bloomer; fine for exhibition.

Of decorative sorts, Bland's Floribunda will introduce a new race, being perfectly distinct from all others sent out; it will become as great a favourite as the well-known Tom Thumb Pelargonium, and will be seen in every garden and on every window-sill; it is of very short stiff growth, requires no stakes, and will grow and bloom under almost any treatment. Queen of the Whites is a very dwarf, free-blooming, nice variety; the best for small plants.

SCARLET FUCHSIAS WITH DOUBLE WHITE COROLLA.

Emperor of Fuchsias.—This is a very fine large flower; the habit is bad when the plant is young, but when two or three years old it improves very much, and is a fine object in a conservatory.

Eva.—Bright waxy scarlet tube, and sepals well reflexed; good habit; a very nice and attractive kind.

Vainqueur de Puebla.—This is the best double corolla out, and will be as much sought after as Madame Cornelissen was; fine bold reflexed sepals, with a very large corolla, and a splendid glossy green foliage, which is much required in this class. A fine acquisition for the open garden.

SCARLET FUCHSIAS WITH DOUBLE DARK PURPLE OR BLUE COROLLA.

Grand Duke.—This has the largest and closest corolla of any fuchsia I have seen; free flowering. The leaves are smaller than Universal, and an improvement on that well-known kind.

Rifleman.—Similar to Sir C. Campbell, but far superior in every way.

Blue Beauty.—This is a very fine flower; good grower, free bloomer, spreading corolla. One of the best.

Agamemnon.—A good grower, the freest bloomer of all the doubles, and a very showy variety, of good habit.

King of the Doubles.—This will make a grand plant for exhibition; dark scarlet tube and sepals, the latter broad, and beautifully reflexed; the corolla very large and long, of a rich purple colour, and distinctly striped with red. In habit this is remarkably good.

Norfolk Giant (or Norfolk Hero).—This is a fine double variety, scarlet tube, and sepals very large; purple corolla; good habit and grower; small leaves, and superior to Universal. One of the best.

To these I would add, for decoration,—Grand Admiral, a good fuchsia, either for decoration or exhibition, fine for small pots; Alherta, a very pretty dwarf fuchsia, a free bloomer, with small leaves, fine for the table; Monster, the largest ever sent out, the corolla measuring from 2 to 2½ inches over, as large as a small rose, short stiff habit; the immense size and the abundance of its blooms, and its good habit, make this a desirable variety.

H. CANNELL.

Fuchsia Nursery, Woolwich.

DIG DEEP.—Baron Liebig sagaciously observed that all the attempts of Messrs. Lawes and Gilbert to grow clover continuously, by heavily dressing the surface soil with various manures, failed, because these manures never reached the subsoil or feeding ground of the clover roots, the top soil having arrested and fixed, or appropriated those manures, which really ought to have been buried and intermixed with the poor subsoil. In a rich old garden, where the subsoil had been long and well fertilized, the same gentleman could grow red clover annually. It is very probable that only enough of the manure we apply to the surface reaches the subsoil in eight or twelve years, so as to enable us to take a red clover crop once in that period. The young clover plant thrives well until in the spring its roots descend to the subsoil, and then it perishes for want of proper nutriment. When the clover crop was first introduced into this country and Germany, clover could be frequently grown; but it appears now to have exhausted the small store of its elementary constituents which existed in the subsoil. It is not unreasonable to attribute to the same cause the frequent failure of our deeprooted turnip crops. Many of us are not aware to what depth the roots of annual plants will penetrate where there is a free passage for the roots and for air and water. In a clay pit belonging to my neighbour, Mr. Dixon, of Rivenhall, which had been somewhat undermined for brick earth, a mass of earth twenty feet thick fell over loosely, and was afterwards sown with parsnips. My friend, observing a fine one, desired his man to pull it up, which he did, and the vertical root measured 13 feet 6 inches; but it was evidently longer, for it had broken off and left a piece of its root still deeper in the soil. Lucerne has been known to go very much deeper than this parsnip. The imperfect development of some of our cereal crops arises from an ill-conditioned subsoil. Wheat roots occupy the subsoil to the depth of four or five feet, therefore the condition of that subsoil as to manure and drainage must materially affect the crop, as we see by the yellowness or "going off" of many wheat crops in May, when the roots attempt to search for food in the un-aërated and unmanured subsoil. It was not known until discovered by Way, and confirmed by Liebig and others, that a few inches in depth of surface soil has the power to fix or retain all, or nearly all, the food of plants which our manure contains, such as potash, phosphate of lime, and ammonia, thus preventing its passage into the poor subsoil.—*Mech's Lecture on Modern Tillage.*

Correspondence.

WORMWOOD AND CHOLERA.—It would be well to have it generally known throughout the country that wormwood is considered a preventive of the attack of cholera. It is to be taken inwardly as well as applied outwardly. The herb may be scalded to make ready for use, the same as making tea, or it may be boiled as coffee. A wine-glass of it must be taken the first thing every morning, and a little at any time during the day to be taken just as it is, without mixing with anything. A little must also be put among the water every morning to wash the hands and face previous to going out of doors. This precaution has been adopted at various places, and considered very beneficial as a preventive of the attack of cholera, and prevention is always better than cure. The virtue of wormwood was held of vast importance by the Romans, hence it is called Roman wormwood. It strengthens the stomach, the appetite, the nerves, the voice, the eyes; it purifies the blood, and gives strength and vigour and courage to the body. No ancient place around this country could be found at one time that had previously belonged to the Romans, but wormwood was to be found growing abundantly. At all old homesteads, castles, and stations, wormwood flourished and grew spontaneously, but although once plentiful, and found to be growing wild everywhere almost around us, has now to be cultivated in the garden for security. I have often recommended this herb privately to those individuals who much enjoy a glass of "bitter" to quench the thirst, and nerve them in the morning for work. I have advised them to try wormwood. It never gets stale or flat, but is always a teller as a bitter draught. As this most lamentable pestilence, the cholera, is spreading among us, it would I think be well to adopt this homely preventative at once by every one, and also to set about cultivating this valuable bitter herb more generally than is at the present time thought about.

A. D. ALLASON.

Replies to Queries.

Ericas to Grow and Select.—I have seen in former issues of the GARDENER'S MAGAZINE some admirable treatises on the cultivation of heaths, and instead of going over the old ground I will endeavour to sum up, for the benefit of "A Young Gardener," who has forwarded a letter of inquiry on the subject, the rules to be observed in the treatment of these plants. The heath house should be light, airy, and dry. It must be heated to keep out frost, but should at all seasons be kept as cool as possible (within the limits of safety), and freely ventilated. Soft-wooded plants should never be mixed with heaths, but many hard-wooded plants, such as Hedaras, Tetrathecas, &c., agree well with them. The soil for heaths must be good peat, not such as may be found in Lincolnshire bogs, but Wimbledon or Shirley peat. For the freer-growing kinds, Epping Forest peat is very well, but it is not so good as that from Addington Park or Wimbledon. With the peat incorporate a fourth or fifth part of clean silver-sand. Those heaths that flower in the autumn should be repotted in March or April; those that bloom in spring and summer should be repotted as soon as they begin to grow after the bloom is over. The potting must be well done; the drainage especially must be perfect; if the roots form a hard ball, and it does not appear advisable to break it (which, generally speaking, it is not), put a few clean pebbles round the ball, and in filling in press the soil very firm. By this procedure you will ensure the admission of new roots into the new stuff. During the summer, the plants should, if possible, be kept in a bed or frame facing the north. The pots should stand on flags or slates, to prevent the entrance of worms. Shade slightly when the sun is very hot, but do not put the plants under the shade of large trees, for the drip will poison them. If kept in the house all the summer, keep air on night and day, and do not shade the top of the house constantly, or the heaths will be drawn. A roller blind is the proper thing, and the proper way to use it is to draw it down for about two hours only at midday in the hottest weather. In September the plants should be housed and put near the glass. Give plenty of air. Throughout the winter an average temperature of 45° will keep them admirably. At all seasons keep them moderately well watered. It is a mistake to suppose they dislike moisture; at the same time excess of water or a sour condition of soil are highly injurious. A very good collection might be wintered in a common pit, with the exercise of care during cold weather to keep them comparatively dry and safe from frost.

A Selection of 100 Species and Varieties of Ericas.—These comprise the most useful and most beautiful in cultivation, and none of them are high priced. Probably at any first-class nursery, one good plant of each might be obtained—that is to say, the collection of 100 sorts for £15; perhaps for less. Aitonians, A. superba, amabilis, ampullacea Barnesii, Andromediflora, Archeriana, ardens, aristata major, a. superba, Austiniiana, barbata major, Bergiana, Bowieana, Bruniodes, Caffra, Cavendishiana, candidissima, Candolleana, cerinthoides, c. magna, Clowesiana, colorans, c. verna, cubica minor, depressa major, d. multiflora, Devoniana, elegans, Eweriana superba, eximia, e. superba, Fairrisna, flويدa, f. campanulata, gemmifera, gracilis autumnalis, g. vernalis, grandinosa, Halfordiana, Hartnellii superba, Holfordiana, hybrida, hyemalis, infundibuliformis, insignis, Irbyana, Jacksonii, jasmiflora alba, Jubana rubra, Juliana, Lambertiana, Linnæana superba, mammosa major, m. pallida, Marnockiana, Massonii, M'Nabiana, melanthera, metuliflora bicolor, mirabilis, mutabilis, nitida, oblata, Parmentieriana rosea, Paxtonii, perspicua erecta, profusa, propendens, pulcherrima, regerminans, retorta major, rubro calyx, Savilleana, scabriuscula, Shannoniana, Sindryana, splendens, Sprengelii, suaveolens superba, tricolor coronata, t. elegans, t. exquisita, t. flammea, t. impressa, t. insignis, t. Kingscottii, t. rosea, triumphans, ventricosa Bothwelliana, v. coccinea minor, v. grandiflora, v. magnifica, v. rosea, v. tricolor, vernix coccinea, vestita alba, v. coccinea, Victoria, Webbiiana, Willmoreana.

W. F.

Variegated Ivies and Hollies.—J. E., Dunstable.—The following are the most effective of the variegated ivies: Hedera Canariensis marmorata and H. C. variegata, Hedera helix, Marginata Cullisii, Marginata robusta, Arborea aurea maculata, Arborea minor luva, and Arborea New Silver. The last named is the variety lately sent out by Messrs. Lucombe, Pince, and Co.; it is the most effective of all the arborescent forms of variegated ivies. Of hollies the following are the best; they are all varieties of *Ilex aquifolium*: Flammea angustifolia, Gold Milkmaid, Bronze, Aurea nana, Aurea myrtifolia (this is one of the best for beds in winter), Gold Queen, bicolor (this bears abundance of berries), Silver Milkmaid, Handsworth New Silver Striped, and Silver Queen.

Variegated Geraniums.—Alice.—You will certainly not find in any catalogue first-class variegated geranium seed. The majority of variegated geraniums are not seedlings, and the best seed cannot be depended on to produce variegated varieties. Without knowing it, you have put a query of a most solemn nature, for it opens the great question if variegated geraniums can be raised from seed at all. It is quite certain that variegated geraniums can be raised from seed, but the raisers save their own seed, and usually keep it, and the plants produced from it, under lock and key. The seedsman you first name can supply good zonal geranium seed. It is our rule not to name traders, except in peculiar cases, and on the present occasion to recommend any one house in particular would be most unfair.

Pansies from Seed.—W. B., Devon.—Pansy seed may be sown at any time from the 1st of February to the 1st of August. Now is a good time, because the plants will have the summer before them for flowering. Sow in pans filled with light rich soil, cover with a mere dusting of soil, and keep the pans in a warm rather dark place till the seed sprouts. This it will do in about ten days. Do not force the plants on in heat; pot them in a mixture of yellow loam and leaf-mould equal parts, with a half part of sand added. Plant them out in April. Pansy seed sown now may be expected to bloom in about ten weeks from this time. If you will forward your name and address in full, the books mentioned shall be forwarded gratuitously.

Salsify, the Vegetable Oyster.—R. W. B.—This excellent root is not sufficiently appreciated, or it would be much more commonly grown. Any ordinary good sandy loam will suit it if deeply dug some time ago, and laid up in ridges to the frost. In the event of having to prepare ground for it now, trench two feet deep, and put manure at the bottom of the trench. Sow in April, in drills fifteen inches apart; when the plants are up, thin to six inches in poor soil, and to nine inches in rich soil. The roots are usually taken up in November, and stored the same as carrots, but some cultivators leave a few in the ground for the sake of the shoots they produce in the spring, and which if cooked before they become stringy are by many highly esteemed. To convert the root of salsify into vegetable oyster, it must first be boiled till tender, then be mashed up with butter, and lastly be fried, a nice brown. It is then said to resemble oyster patties. It is certainly a very tasty dish, without any reference to its imitation of oyster.

Early Forcing.—Sub.—In proportion to the heat should be the amount of moisture, as also the circulation of air. We infer from your statement that the atmospheric moisture is much deficient. Is there, however, any source of bottom-heat which produces atmospheric moisture? Roses, and in fact most shrubs emerging from a state of partial torpidity or rest, are very averse to what is termed dry heat. Our advice is to use as much atmospheric moisture in the afternoon, in combination with a circulation of air, as will deposit dew on the leaves. A much less amount may be used from daylight until noon. Drah is a good colour to paint your house to show off vegetation; as to matters of cultivation, it is quite of secondary importance. The management of the atmosphere carries the chief weight. Achimenes coccinea cannot be got well through the winter—more light in conjunction with heat is wanted. Pot off some now which were rested early; plunge them in bottom-heat without water; as soon as up, transfer them in groups to pots or pans, and cultivate as you would a balsam. Pot again once a month for succession from those at rest. Plunge gesnerias in bottom-heat, and treat them as achimenes. Use a little water, increasing it with increased vigour. Your temperature is rather too low; if sunshine occurs, run the glass up to 75° or even 80°, provided there is a little motion in the air. A cold greenhouse will suffice for camellias.

Shady Bank.—R. B.—When grass will not grow for want of light, spargula is no use. Nothing better for the bank than periwinkle, of which there are several varieties; the minor white will make the best bank. Common English (not the large-leaved Irish) ivy would make a splendid clothing for the bank in a few years. Moneywort is a first-rate thing to cover a bank, the plants to be inserted on the upper edge, whence they will soon trail to the bottom. Violets would not flower well there. Primroses would do, but they look poor in the autumn.

Exotic Ferns.—Subscriber.—These should be repotted when just about to commence their new seasonal growth. The soil must depend upon the species, but as a rule turfy peat two parts and sandy loam one part will grow stove ferns well. Some like rotten wood, and they are all partial to leaf-mould. There is no cheap work on exotic ferns. Mr. Lowe's work in eight volumes is the best yet produced.

Asphalt Walks.—R. W. Robson.—In "Jones's Gardener's Receipt Book is the following: "The place intended to be asphalted must be previously levelled, then put on it a coat of tar, and sift some road-sand or coal-ashes all over it very thickly; after this is dry, repeat the operation until you have got four coats of tar, and as many of coal-ashes or road-sand. You will then have an excellent, clean, dry, hard path. It will make excellent walks or floors for sheds, out-buildings, &c., and will wear for many years.

Slug-trap.—Simson.—The Somersetshire trap you inquire about is not intended for slugs, but for mice. It consists in half filling a jar with greasy water, and placing it sunk to its rim in the ground. The mice go in, but cannot get out, and are drowned; and usually slugs go in too, and are likewise drowned, though slugs can swim, and to climb up up a jar is no trouble to them.

Potted Peach Trees.—R. Bakewell.—No dependence can be placed on peach trees for a crop of fruit this year, if the potting has been delayed till now, and especially if they were taken up or out of pots in November last. When potted in November, fruit trees begin to make new roots at once, and continue growing at the root all the winter, whereas if delayed till February they are then beginning to start their buds, and there is not enough root action established to enable them to carry fruit. The house will no doubt accommodate them well if freely ventilated. Feeders are of use chiefly to supply more moisture to plants than they can have by ordinary watering. The Noblesse, Royal George, and Violette Hative are all first-class peaches; the first is the most ornamental when in bloom, as it has large flowers, and it is also the best peach to choose for general purposes, as it is a constant bearer, and the fruit unsurpassed among peaches.

Artillery Plant.—Miss Mary.—The plant is *Pilea allitrichoides*, or Pistol plant. It is a native of the West Indies, and a very elegant and interesting subject for stove and greenhouse culture. We have frequently used it to furnish Wardian cases, for which purpose it must be grown to a good size in pots, and be plunged in the place it is to occupy, and it will continue to grow and bloom from May to October in the temperature of a dwelling-room. The minute, fern-like leaves and reddish pins'-head sort of blossoms, fit it well for association with fine-leaved plants. It is named the Artillery or Pistol plant, because when sprinkled with water on a hot sunny day, the flowers emit little puffs of pollen like discharges of smoke from fire-arms.

The Gardener's Magazine.

SATURDAY, MARCH 2, 1867.

THE AFFAIRS OF THE INTERNATIONAL HORTICULTURAL EXHIBITION OF 1866 are being slowly but effectually wound up, and the latest work of the Executive is of a most satisfactory character. The "Report of Proceedings" just issued and distributed amongst subscribers, contributors of papers to the Congress, and others having general or particular claims, is not only a creditable document, but a very important contribution towards the history of botanical and horticultural science, and as such will be valued for all time to come. It is a substantial octavo volume of 428 pages, beautifully printed, abundantly illustrated, and comprising in its contents a complete record of the proceedings from the first dawn of the idea in 1864, to its realisation in the summer of 1866, and the temporary closing of accounts in November last. As only a limited number has been printed, some account of the contents of this work may be useful to many of our readers. There are complete lists of Officers, Patrons, Subscribers, and Guarantors, lists of Foreign Visitors to the Botanical Congress, and of the authors (with their subjects) of papers contributed thereto; a Catalogue of the Exhibition, and the Schedule of Prizes, followed by lists of Awards, Jurors, Exhibitors, and lastly of the music performed on the several days of exhibition. The "Summary of General Proceedings" gives a lucid account of the steps and stages of the undertaking from first to last. It is followed by a report of Proceedings of the Congress, and by a selection of the several papers presented and discussed, some of these papers being elaborately illustrated.

We gladly avow the gratification experienced on receipt of this noble volume, but it is a gratification not unmixed with regret that the Executive have forgotten some essential things, and have apparently allowed mean motives to influence them. At page 19 of the report will be found a complete list of subjects proposed for discussion, and of papers presented to the Congress. At page 42 commences the reproduction of a selection of the papers in full. The catholicity of the selection is open to question; indeed it is next to impossible for those who know what jealousies, prejudices, and personal animosities lie below the surface of horticultural discussions, to avoid the conclusion that some papers have been admitted because their authors were held in favourable personal regard by the committee, and other papers were excluded because their authors were not on the roll of favourites, or perhaps were on the roll of those who were to be tabooed if possible, even if at so tremendous a price as the degradation of science to serve personal interests. Amongst the papers inserted is that ridiculous essay by Mr. Wills "On the Sporting of Pelargoniums and other Plants," in which, in opposition to recorded facts, he expresses his belief that no variegated leaved pelargonium has ever been raised from seed. The impartial critic will be tempted to ask if Mr. Wills has been made the most of in the interests of a journal to which he contributes papers quite in keeping with its literary standing. The three papers by Mr. Rivers are undoubtedly interesting and valuable, but many of the points elucidated in them have been treated at such length for many years past by their author in his contributions to our contemporaries, that we cannot avoid associating with their appearance in full the existence of a delightful harmony between the Executive and Mr. Rivers—a harmony not altogether void of principle and interest. If every paper contributed had been reproduced in full, we should point to Mr. Rivers's papers as amongst the most useful of all for a place in a permanent record, but the omission of several important and original contributions compels animadversion in a case where it would be most agreeable to avoid it. Three good papers—namely, that by Professor Karl Koch on the classification of plants; that by Professor Morren on the effects of coal gas on plants; and that by Professor Schultzenstein on the presence and source of nitrogen in turf or peat, are presented in the original text, but they would be

far more useful to a majority of the subscribers if accompanied with translations, which could have been furnished at but little expense or trouble. Amongst the papers omitted, the following appear from their titles to have merited a better fate, and we fear that motives not unmixed with personal feeling must have prompted their omission: Mr. Bull, of Chelsea, "On the Relation of Horticulture and Botany to Mankind in General;" Mr. Hibberd "On the Naming of Plants;" M. Krelage "On the Names of Garden Varieties;" and Signor Triana on the Mutis collection of drawings of the plants of New Granada. The insertion of these papers would not have added £10 to the whole expense of the printing of the report; their omission damages the report, and reflects unpleasantly on all who have had a hand in its production. To think that after all there should mingle a little shop with the winding-up of this great affair! *Acta exteriora indicant interiora secreta!!!* The lists of awards, jurors, and exhibitors is a most interesting and valuable section; and it appears that great pains have been bestowed in rendering the particulars as accurate as possible. Possessors of this beautiful volume may now dispense with the official catalogue that was sold in the exhibition tent, and which was unavoidably crowded with inaccuracies, for they have here a complete and correct record of all exhibitors, all winners of prizes, and the names of all the plants in the most important collections.

It only remains to remark upon the balance-sheet, the principal items in which are the following: Subscriptions paid, £5,604; receipts by payments on entry and sale of tickets, £9,960; sale of catalogues and advertisements in ditto, £301; sundry receipts, £151. The total receipts were over £16,018. On the other side we find entries as follows: Paid Unite for tents and fittings, £3,666; paid Royal Horticultural Society for use of ground, £300; advertising, £998; prizes awarded, £2,000; banquet expenses, £970; music in Royal Horticultural Gardens, and conversazione, £304; salaries and gratuities, £1,641; Gardeners' Royal Benevolent Society, £1,000. There is a balance of cash at Coutts and Co.'s bank amounting to £2,000, on which interest is accumulating, and another balance at call amounting to £438. There remain to be paid for out of these balances the expenses of printing the Report (£637), and of levelling the ground on which the exhibition was held (£130). Probably when these items are disposed of, the Executive will still have about £2,000 in hand, for the interest on the larger portion of the balance will amount to something by the time the account is closed. The question is what shall be done with the money? It is a question of considerable importance.

Turning again to the credit side of the account, we cannot forbear remarking that the lumping system has been carried a little too far. We cannot discover whether there was a gain or loss by the sale of catalogues, for the entries in respect of printing are all on the lump plan. So in respect of salaries, gratuities, &c., we obtain no hint of the £300 understood to have been presented to the three secretaries, Messrs. Moore, Masters, and Hogg. No one grudges them so small an acknowledgment as £100 each; it might as well be boldly stated in the balance-sheet as lumped in under the ambiguous but comprehensive "&c." Well, then, as to the surplus, an offer has been made to the Royal Horticultural Society of means for founding a library of horticultural and botanical books, which up to the present time has not been very graciously treated by that august body. Indeed, the Society's last report treated the International Exhibition in a rather ungenerous manner, so that it is still an open question as to how the surplus is to be disposed of. We will take this opportunity of commending to the consideration of the Executive a good old saw which prompts us to be just before we are generous. If it was right to acknowledge the services of the secretaries by means of honoraria, the judges we think may claim a like consideration. It is not generally known that *the judges gave their services gratuitously*. They did so in precisely the same spirit that the guarantors put down their names, in the spirit of anxiety for the success of the undertaking; and as they gave their time, strength, and talent, they assuredly are entitled to some share of the surplus; many of the judges could ill afford the sacrifice they made in behalf of this great undertaking. Now that it has been crowned with success, they who contributed no small share towards its success are surely as much entitled to generous consideration as the secretaries, and have quite as good a claim to a share of the overplus which the committee are so much puzzled to dispose of.

THE GENUS FRANCISCEA.

This lovely genus belongs to the Solanaceæ of the tropics, and the species are the most gorgeous of our stove flowering plants—the rich mauve-coloured flowers harmonize so effectually and beautifully with the dark, somewhat ovate, shiny leaves, which are thickly and regularly seated upon the young growths. Coming as they do from the interior of the Brazils, their successful management depends mainly upon the knowledge possessed of the physical nature of that peculiar country. There, it is well known, the weather is most seasonal, and the seasons distinctly marked. At one period vegetation is subjected to the debilitating influence of a vertical sun which parches the atmosphere to aridity, following which are deluging and for a time incessant torrents of rain. It is in the latter season that the plants luxuriate and make a rapid growth, their roots fixed in a terrestrial temperature of from 80° to 95°, with an atmospheric temperature of the same power, and highly charged with moisture in the form of floating aqueous vapour. This warm humid atmosphere is peculiarly necessary for the complete development of their leaves and growths, and it is in these situations that that important agent carbon so largely abounds, consequent upon the rapid decomposition resulting from the extinction of vegetable and animal life. Following this condition is the dry season, or season of rest. A low temperature with corresponding dryness of the atmosphere has the effect of arresting growth, consolidating the juices, and thus transmitting the new parts into flowers and fruit, after which a partial deciduous state is brought about, and vegetation remains torpid until the exciting influence of the recurring season again arouses them to activity and vigour. This cursory sketch of the climatic influences to which this genus is subjected will be sufficient to prove how important it is that we should take the opportunity of starting plants into growth at this season, when solar light and heat every day strengthens and aids us in securing all the conditions necessary to a complete development of the functions upon which wood, leaves, and flowers mainly depend. Therefore a bottom-heat of about from 70° to 80° should be secured, and the pots plunged up to their rims, keeping the atmosphere at about the same ratio, also at the point of saturation. If this is persevered in, the plants will imbibe nearly all the moisture they require through the stomates of the leaves and young parts, and thus render watering almost unnecessary; and in this condition they will effectually resist red-spider, thrip, and other similar evils which always beset ill-managed half-starved plants; growth will be quickly made and matured; and if at this stage moisture is partly suspended, still keeping the same temperature, flowers will form, which when expansion commences should be taken from the bottom-heat and placed in the coolest part of the house, where they should be kept until flowering ceases, when a lower temperature must be sought, and the plant exposed to the full influence of the sun's rays throughout the autumn months, in order to harden and ripen the current season's growth, which, if effectually done, the plants will be in a state to resist the dull and almost sunless period of our British winter, without engendering the diseases which too often attack this class of plants, such as growers call fogging, canker, &c., &c., which may in all cases be traced to an incomplete state of the refining process, and the exercise of too little care previous to the plant going to rest.

The species of this fine genus are nearly all worthy of cultivation, but those appended below marked with an asterisk, are especially worthy all the attention that can be bestowed upon them. The magnificent species *Calycina*, recently introduced, far surpasses all other known species, and being a good grower will ere long become one of the leading gems of our plant stoves; and even a limited collection of stove plants will be most incomplete without this valuable addition. The best known species are *Acuminata*,* *Calycina** (major), *Confertiflora** (syn. *aurifolia*), *Lindeniana*, *Augusta* (syn. *ramosissima*), *Eximia*,* *Hopeana* (syn. *uniflora*), *Latifolia*,* *Macrantha*.

J. R. TANTON, F.R.H.S.,

Epsom Nurseries, Surrey.

POTATOES FOR 1867.

At page 556 of last year's issue I gave some account of the potato crop on the trial ground at Stoke Newington, and as planting is now in progress, some particulars, not then available, but likely to be of service to potato growers, have forced themselves upon my attention, and therefore I propose now to make a few remarks supplementary to that report. All our good stocks of potatoes saved from the fearful havoc the disease made here were pitted on the field, and from time to time have been brought home for use. Thus throughout the winter the merits of several varieties have been tested and compared under circumstances of some importance; for if, after such a visitation of the murrain, we can still keep the table supplied with good potatoes, the names of the sorts, and the conditions attending their production, cannot be matters of indifference. Another matter, not altogether unimportant, is the experiment made to ascertain if potatoes in store could be inoculated with the disease. I have always asserted, and that unhesitatingly (see especially pp. 229 and 253, 1865), that when a potato is once ripened, it is incapable of receiving the disease, and that if disease once begins, it is impossible to stop it. There are

but two courses left to the cultivator to choose between; either to take them up, and make use of them in some way as pigs' food, or send them to market, or put them in the mash-tub to furnish wort for cheap brandy, &c.; or, on the other hand, to let the disease have its way, and in due time take up such tubers as remain untouched. No attempt was made in 1866 to save a single root from the disease. Not one was lifted till the haulm had died down, and consequently the autumn was far gone ere the harvest was completed, for rain set in during the first week in August, and continued with few intermissions till the end of October. When the late kinds were lifted, we learnt two facts respecting them: first, that there was an enormous crop, and, secondly, that nearly all the produce was diseased. There was a piece set apart for the whole of the collection, three picked tubers of each. Other pieces were set apart for a few choice sorts to multiply for stock; and there were some twenty rows of twenty yards each planted with sorts selected for home use. Respecting the samples in the bed devoted to the collection, the potato book furnishes the following particulars:—

Sutton's Racehorse.—Entirely destroyed. Not one potato so large as a marble saved from the wreck. Messrs. Sutton have supplied me with sets to begin again. This is one of the best early kidneys known, if got off the ground before July is out, as it may be in fact, and it may be dug for use at the end of May if helped in the early part of the season, and is one of the best varieties that can be planted in a garden.

Hibberd's Improved Fluke.—This was a seedling raised here. The stock found its way, by mistake, to the kitchen, and was consumed. Three sets were planted in the collection, in the hope of recovering a stock of it. They made enormous stools, about half a bushel in all, but not one root was sound enough to keep.

Rintoul's Early Don.—Entirely destroyed. This is a lamentable thing, for this potato is handsome, highly productive, and good in colour, texture, and flavour. First-rate, especially as a market potato.

Golden Drop.—Entirely destroyed, and no matter. Pity it was not destroyed long since, for it was never of any value except as pig food.

Webb's Telegraph.—This pretty white-fleshed kidney was swept off the field. Messrs. Sutton and Sons have supplied sets for this season.

Webb's Imperial.—Entirely destroyed. This was a most remarkable case. There were three fine samples planted in the bed allotted to the collection, and four rows of 20 yards each—that is, 80 yards run—for home use. We did not obtain one sample, and have been obliged to send to Messrs. Sutton for sets, and by their kindness we have enough for a fresh beginning. The loss of this potato was a real calamity, because for many years past it has been one of our best for table use in spring, and towards the opening of summer, for the later it is kept the better it eats. If eaten before Christmas, it lacks flavour, but after the turn of the year it improves, and continues improving until it is too much sprouted to be fit for cooking. At its best it is surpassed in flavour by a few other varieties, and notably by *King of the Potatoes*, which is one of the best flavoured sorts known, but by none is it surpassed in whiteness, fineness of texture, and meanness. There cannot be found a nicer looking potato when well served, and looks are of some importance in these matters. Lastly, it remains to be said in reference to this variety that it is not usually very productive—scarcely so productive as the *Fluke*, which is quite second-rate in respect of fruitfulness; but in 1866 it appeared to have been extravagantly fruitful; the rows were thickly covered with large tubers at taking up, but not a sound one could be found amongst them.

The foregoing varieties are all that were extinguished on our ground by the disease. I shall now name a few that proved extra-good, and first of all let every proper respect be paid to

King of the Potatoes.—This was planted for home use, and makes a respectable appearance daily on the table at the present time. It is unquestionably one of the finest varieties known, having only one fault, and that is yellow flesh. But the texture is good, the flavour excellent, and a careless cook can scarcely spoil it, so well does it hold together, and so dry does it keep for a long time after cooking is finished. In growth it is very robust, and gives a larger proportion of handsome roots than any other variety I am acquainted with. I have weighed six average samples, taking them as they rise from the basket in the storeroom, and I find the average of the six to be 9 ounces. Now potatoes weighing 6 ounces each are a good size for cooking, but in my opinion the larger they are the better up to 12 ounces, which should be the maximum. The best sample of *King* I can find at this moment is a tuber measuring 8 inches in length and 4½ inches in breadth, the weight of which is 22 ounces. This is a handsome root, rather flat, approximating in form to the *Fluke*, and if carefully baked would serve to accompany chops for two people. I have no doubt from the weight it is perfectly sound at the core. This variety produces both round and flat roots, but the largest and handsomest are the flat or kidney-shaped.

Mitchell's Seedling.—By a mere chance a few rows of this were planted, and the produce was enormous in quantity, and the proportion diseased was very small. It is good for both autumn and spring; in fact, it keeps well, and scarcely ever varies in quality, whether dug before ripe, or taken up ripe and kept till far into spring. It is never large, and the average of good samples are less in size than the Ashleafed sorts. The flesh is greenish-white, scarcely mealy, and not well flavoured. It is in fact quite a second-class potato, but its fruitfulness and healthiness commend it to the attention of cultivators who cannot afford to lose a potato crop entirely.

Lapstone.—We got a few out of many. This potato always suffers much when a general outbreak of disease occurs. It is a beautiful root, and when served as it should be the flavour is excellent. It is not mealy, but quite dry, and almost of a nutty flavour.

Prince of Wales Kidney.—I observe that opinions differ as to the value of this potato, but it must be remembered that a great many persons write about potatoes who are quite incompetent to form an opinion—who, in fact, scarcely know a good potato from a bad one, whether on the ground or on the table. But with the most competent of judges, opinions will differ, because soils and climates differ, and a potato that has a high quality in one place may have a poor quality in another—to say nothing of the occasional sending out by little local seedsmen of any sort they can get hold of cheap under the name of a new sort that is selling at a large figure. We should have been had off last autumn but for this variety, for in the midst of a field of corruption, this sort came out scarcely touched, and was very useful during November and December. The crop was good in quantity, and consisted in great part of roots weighing from 6 oz. to 10 oz. each, though 15-oz. roots were not hard to find amongst them. In colour and texture it is far inferior to *Webb's Imperial*; in flavour it is inferior to *Lapstone*; but if we had cast our lot upon the two last-named

noble varieties, we should have been without potatoes altogether. So much then for "the boon," as the raiser properly called it.

Pheasant's Eye.—A short row of this gave a good crop. It is an excellent variety.

Milky White.—A great crop, scarcely a taint of disease, and the tubers of even size throughout—neither large nor small. As to quality, there is nothing better: it should be largely planted in every garden in the land.

New Round Scarlet.—Very productive and sound, and apparently one of the best disease resistors. It is an even potato, with a glossy red skin, averaging large, and very prolific. When cooked, the flesh is white, moderately mealy, and as to flavour bearable, and that's all. It is a first-rate poor man's potato, giving a large yield of wholesome food, and safe in event of disease occurring.

Skerry Blue stood well against the plague. This is reckoned a first-rate potato in the western parts of England. It is ugly, white fleshed, not mealy, and almost flavourless. Its fruitfulness, healthiness, and the whiteness of the flesh are three admirable qualities.

Mona's Pride.—This has become famous, and deservedly so, for it is one of the best in cultivation. It has no bad quality, in which it ranks with the *King*, and that is the flesh is yellow. Otherwise it is good in flavour and texture, and eminently serviceable as an esculent. In 1866, its behaviour was admirable here. The crop was ripe on the 8th of August, and averaged twenty to forty tubers to a stool, the greater part of them handsome and of good size.

Fairbairn's Pink.—This new variety did well in respect of escaping disease, and in every other particular was good. The flesh is white, mealy, and of excellent flavour.

Paterson's Victoria.—A short row was planted. The result was a heavy crop of handsome tubers. Quality all that could be desired. It is a capital sort for the table—white, mealy, and good flavour, and not easily spoiled by the cook.

Paterson's Regent.—Saved by the skin of its teeth. From three stools in the collection and six elsewhere we managed to pick out about six roots worth keeping and cooking; and by the way, they were not worth cooking, for they were waxy, evil-flavoured, and emitted an unpleasant odour. It is an ugly potato, to begin with; no one who understands potatoes will expect any good from it.

Paterson's Napoleon.—Good every way. Very prolific, and as compared with the best potatoes we have, fully deserves to be classed as second-rate. With the view of again testing the whole of Paterson's varieties, I have obtained a complete set from Messrs. Hooper and Co., of Covent Garden, who have obligingly sent me clean picked samples. We have them now three times over, and shall plant them in three separate plots of ground, in order to obtain the fairest results possible with the means at command here.

The foregoing are all that I see reason to refer to, especially in reference to the potato crop of 1866. The samples to be planted this week are now (and have been for some time past) displayed on the fronts of the bookshelves, and on the tables, and in the windows of my study. Every root is marked with a number corresponding to its place in the potato book, the ink used for the purpose being that indelible mixture of sulphate of iron, lamp-black, &c., &c., which is used for zinc and other labels out of doors. Most of the samples are well greened, and have short, plump, purple shoots a quarter of an inch long. I shall select from them a few for special mention, shaping my notes so as to be useful, if possible, to many of our readers.

Abson Ashleaf.—I was too late in looking after this last year, but I have some good samples of it supplied by Mr. John Scott, of Yeovil, Somerset. This is at once an early and a late variety: early if planted in a warm soil, ripening off by the first week in July, and in a cold soil ripening before July is out; but late in the sense that if kept cool it is reluctant to sprout. It is fruitful, a good grower, and one of the best potatoes that can be eaten. I have known it three years.

Pink-Eye Radical.—A tawny round potato, hard as iron and heavy as lead, eyes very shallow, and altogether much like Daintree's Early in appearance. The flesh is quite white, very mealy, and of excellent flavour. One of the best round potatoes in the market. With these samples came from Mr. Pierpoint, of Warrington, the following note:—

"The large tubers No. 1 are put into pits in the usual way at lifting time. In the spring taken out, and any sprits knocked off. This causes the potatoes to respire freely, and at every eye. These are planted whole for stock seed, and the result is a greater crop of healthy medium sized tubers later than No. 2. The reason for planting largest sets of the whole potatoes is to renew the stock true and vigorous. The reason for planting whole is to obtain a greater number of medium sized tubers. No. 2 are small potatoes of same crop. These are placed in spritting boxes immediately upon getting up, and kept dry until planting time, when they are set whole. The result is earlier and larger produce, but less total weight of crop than No. 1. To ensure the earliest possible crop, cut a small piece, say one-eighth of an inch, off each No. 2 a day or more previous to planting. The reason for 'boxing' at lifting time is that by that means one or two early strong sprits are secured, and this very materially aids in obtaining size and earliness of crop." The average weight of No 1 is 5 oz., a fair cooking size, that of No. 2 is 2 oz. The small size has one fat sprit an inch long from the crown eye; the other eyes have not started.

Grimsdale's Early Kidney.—From Messrs. Grimsdale and Sons, Uxbridge, Middlesex. This is evidently one of the Ashleaved race. I know nothing of its growth, but the samples sent to me are handsome, very even and uniform, and a dish served to table established its character as first-rate in texture and flavour.

American Red.—This, with several other varieties that were wanting, has been received from Messrs. G. Gibbs and Co., 25, Down Street, Piccadilly. The tubers are large, round, slightly flattened, rounding up boldly from the eyes, which are depressed, but not deeply. The colour of the skin is a mixture of fawn and pale red, with much roughness. The size and beauty of this potato distinguish it among hundreds, so that the uninitiated would be likely to select it as promising good things by its distinct and handsome appearance. It is as good as it looks; the flesh is as white as snow, the texture fine and quite mealy, and the flavour first-rate. It is reported by Messrs. Gibbs to be a heavy cropper; on that point I can say nothing now, but on the other points I speak from observation.

Goldfinder.—For this, with several others, I am indebted to Messrs. G. Gibbs and Co. It would be needless to name it here, except that it enjoys some sort of repute as a good variety, whereas in truth it is a very bad one. Having known it several years, I can say without hesitation that

it is very subject to disease, and that at its best it is not good enough for any table. It is a great cropper, but if it be regarded as a cattle food it is at once beaten by the Chardon, which is equally fruitful, more healthy, and may be put upon the table without causing nausea; in fact a Chardon well cooked and piping hot is not to be despised with a steak hissing from the gridiron. I speak from experience, having eaten both lately at a game-keeper's cottage after a walk of eight miles, some part of it up stiff hill-sides, and some through bogs where, if one were to lie down, one's earthly history would be closed instantly.

Ashtop Fluke.—Messrs. James Carter and Co., of High Holborn, have forwarded samples of their new variety hearing this name. It is a handsome kidney, said to be bred from the Ashleaved and the Fluke, and in its appearance and qualities it agrees perfectly with its alleged origin. Of its growth I can say nothing now, but as a table potato it leaves nothing to be desired; it has the whiteness and meanness of the Fluke, and the fine flavour of the Ashleaf. It is a capital keeper, for my samples have been in a warm room some months, and are now barely started.

The foregoing are all that appear to be desirable to remark upon at present amongst the varieties added to the collections for 1867. Respecting the selection of potatoes for garden cultivation, it must be evident to all who are influenced by reason rather than prejudice, that to grow several varieties is by no means so absurd a practice as some shallow, hasty, and narrow-minded people imagine it. It is common enough to hear some over-wise gardener say, "Two sorts of potatoes are enough for me." Some go as far as six sorts, but always with a protest against the multiplicity of varieties that have places in the lists. There is one thing certain, the man who grows all the varieties he can obtain must grow a vast amount of rubbish. Bad sorts are more plentiful than good, and very many cultivators who are not new to the business are not fully aware of the points that constitute good quality. But in avoiding the error of too many, it is not desirable to run into the other extreme of too few. I think we may safely say that wherever the table is to be supplied the whole year round with good potatoes, there should be at least a dozen sorts grown; and from time to time new sorts should be tried with a view of multiplying the chances of a crop in the event of disease occurring. We are well supplied with potatoes of the finest quality, and with plenty to spare. A gift of a bushel of good potatoes now and then where wholesome food is not over-abundant, is not a bad way of utilizing the results of experimental culture, and we are never much troubled about our surplus. But how would it have been with us since October last, and henceforth till June or July next, if in 1866 we had trusted to our own Improved Fluke, Rintoul's Early Don, Webb's Telegraph, and Webb's Imperial? Here are four as good sorts as can be chosen—sorts that compel admiration by that best of tests, the eating. Yet if we had trusted to those four, and had covered ever so much ground with them, probably we should not have had a potato to eat of our own growing for at least six months of the whole year.

(To be continued.)

AN EFFECTIVE MODE OF HEATING.

Observing many and grievous complaints of several correspondents in the GARDENER'S MAGAZINE and *Floral World*, touching the havoc made by the late severe weather in their respective plant establishments, and thereby raising the important question of heating the said structures, I am induced to set forth, in as brief terms as possible, the performances of a most useful apparatus, whereby, with a minimum of attention, our entire stock has been preserved unscathed. Our greenhouse, which was constructed from my plan two years ago, is 23 feet long, 12 feet wide, and 14 feet high. It is fitted with the usual 4-inch hot-water service piping, very sparingly supplied. The boiler is multitubular, the tubes are vertical; it is circular in form, and surrounded by a sheet-iron casing; its height is under 4 feet, and its diameter is 18 inches. The fuel is supplied from the top. The boiler stands on its own base, and requires no setting or brickwork of any kind, save a small smoke shaft. It is fitted with a self-regulating apparatus, on a principle at once simple, scientific, and unfailing—to wit, the expansion and contraction of mercury acting in conjunction with a balanced air valve, and thereby regulating with faithful exactitude the quantity of air requisite for the due combustion of the fuel. The advantages of this invention are extreme regularity of temperature in the pipes, careful utilization of the heat evolved from the fuel, and consequently great economy of fuel (one bushel or four pecks of ordinary gas coke sufficed to keep our apparatus in full operation in the most severe weather, without any attention, for twenty-four hours and more). Its other advantages are great saving of labour, independence of action in respect of careless fixing, and the vicissitudes of draught incidental to varying conditions of wind and weather; and, lastly, the complete and utter abolition of "night stoking," notwithstanding the dictum of an esteemed correspondent in the GARDENER'S MAGAZINE for this month issued against the possibility of so desirable a climax. I assert this with the confidence acquired by two winters' practical and personal experience of the working of the apparatus, and I think no one will venture to dispute the severe character of the weather we have lately had to contend with. Out of many hundreds, we have not lost a single plant from the effect of frost; on the contrary, to use the words of a friend who saw them lately, the whole stock rejoice in the most robust health, which fact, considering the circumstance of our being amateurs and mere beginners, I leave to tell its own tale as to the efficiency of our heating arrangements. The system is capable of extension to almost any limit. One friend, who adopted it from my recommendation, heats seven different structures from one boiler, and he speaks most highly of its action. In conclusion, I beg to say that in publishing this statement I have no earthly interest or motive whatever beyond a sincere wish to benefit my brother amateurs, and to call the attention of the horticultural public in general to the merits of a most ingenious and effective invention. The boiler is patented, and is manufactured by Mr. Bower, St. Neots, Huntingdonshire.

Belloft House, February 13, 1867.

R. ROADLEY DIXON.

DOGS' TALES.—Three dogs belonging to M. de S. and M.P. of Bordeaux, went hunting on their own account, but one of M. de S.'s dogs failed to return, and the other two only turned up late at night covered with sweat, blood, and mould, and evidently quite worn-out with fatigue. They both made off early next morning, and returned again at night in the same state as before. This continued for several days, when at last the third dog made his appearance in the most emaciated condition between his two liberators. It appears that the emaciated animal, in pursuit of a rabbit, had gone full pelt into a hole, from which he had been unable to extricate himself. His friends had to dig him out, and were several days about it.

ON SOME EXPERIMENTS IN TEMPERATURE.

BY G. HADWEN, ESQ., F.H.S.

(From the Journal of the Royal Horticultural Society.)

Being interested in horticulture, yet, unfortunately, denied a climate suitable for trying outdoor experiments, it occurred to me that if I made an application to the Council of the Royal Horticultural Society, they might perhaps permit my experiment to be tried at their garden at Chiswick, already rendered famous by the valuable thermometrical readings that have been taken there for so many years. I therefore wrote and asked that a few additional daily observations might be taken for me. This application they in the kindest manner acceded to, and the subject was warmly taken up by Mr. Robert Thompson, who was only too glad, he wrote me, to be of service to horticulture. My application was that, in addition to the daily maxima and minima in the open air, the maxima and minima of a south wall should be taken, and the maxima and minima of the large conservatory. In this latter case I asked that the progress of the crop should be noted, as also when fire-heat was used. Thus the matter rested till I went up to the Great International Flower Show, where I encountered the Rev. M. J. Berkeley, who invited me to write a few notes explanatory of my reasons for making this request, so that when the result of the observations was published in the Journal of the Society, the Fellows would be better able to understand the value of the tables. This, I thought, was more than I was able to perform; but subsequently I have seen in the Journal of the Society the paper on "Border-heating" by the Rev. W. Kingsley, and his concluding remarks have not only accorded with my own opinion, when he says, "I am sure that unless our experiments are based upon some principle to begin with, they will never be of value for making correct inductions; and so I shall be glad to give some time to experiments of a scientific kind in order to obtain results that, as an individual, I should never live long enough to see, but which by the united efforts of many may be arrived at in a few seasons;" but I have also felt such a strong desire to assist him in his laudable efforts, that I have concluded to write a few notes to try and draw the attention of the Fellows, not only to the value of such scientific experiments, but also to point out to them my reasons for thinking the garden of the Society at Chiswick possesses peculiar advantages for such experiments. The first is, that to be of any use to horticulturists, it is of the utmost importance that the experiments should be made by some one of experience, whose interest in horticulture is undoubted, who has time carefully to observe all changes, and in whom every confidence can be placed as having no previous prejudices that could warp his judgment, and so prevent him having the full benefit of all his perceptive faculties; secondly, that the experiments could be tried in a suitable locality; thirdly, that the place should be the one where the experiments could be tried at the least possible expense. I think that all who know the garden of the Society at Chiswick will join with me in thinking it offers all these advantages—in its staff employed under the Garden Committee—in its climate, as we are told that in July the valley of the Thames is as warm as any part of England, not excepting the southern coast of Devonshire and Cornwall; and since the garden has all the sorts of houses required for the experiments, it would only need a light expense, such as making a warm border, buying wall-sheeting, and supplying the thermometers to carry out any experiments that might be required. I am one, if more can be found, willing to join in the expense of the following experiments, say, for two or three years.

That the maxima be taken each day and the minima each night, in the open air, in the shade, on a south wall exposed to the sun, on a south wall well sheeted up each night, as also during the day, if required, which practice is to be noted, in a heated border in the open ground at the same depth, both borders to have plants in them wall-trees and standards; the sheeted-up wall to be also used in like manner; in the orchard-house, glass wall, in the lean-to vinery, and large conservatory. In each case the progress of the crop to be mentioned, and when fire-heat is used in those that have it. My reason for making this proposal is because I think we do not fully realize the power of sun-heat any more than the advantages of border-heat. Who was prepared to find, what the experiment of this year has shown, that a peach tree or vine planted against the south wall at Chiswick would, during the warm sunny days, have had a much higher temperature than was required to bring the crop of grapes to a successful maturity in the large conservatory? Turning to the minima table, I think there is every probability that if a sheet had been employed to check the loss of heat by radiation, we might have said as much for the night temperature also. The disadvantage of unheated glass walls is that the sun in spring advances the trees, and yet the glass is not able to prevent during the night the injury from low temperatures caused either by frost or radiation during clear nights; and the peach trees or vines suffer from this last evil quite as much in the autumn as in the spring, for the trees are by this cause often being put to rest before the crop is ripe. Again, who was prepared to learn that a lean-to orchard house, with the back wall facing the south, had such a manifest advantage over a span-roofed house with the same aspect, as we must believe it has, if in the open air such a wall indicates a heat of 100° without any glass to retain the air heated by its radiation? With respect to border-heating, the Rev. W. Kingsley gives some important information from his experiments, which I can fully believe from my own, though, as I have said, my climate has confined me to experiments under glass. A few years since, I communicated to one of the papers, though at the time it attracted no attention, what very much surprised me. I planted down the centre of a span-roofed vinery I had supplied with bottom-heat to grow Muscats in, some early French vines, with the intention of cropping them till the roof was covered. The catalogue from which I ordered them said some of these very early ones would be ripe nearly two months before the Muscat of Alexandria; yet the result did not give two weeks, and I am still of opinion that with this treatment the Muscat of Alexandria is not a late grape in the meaning of that term. If I am correct, forcing should still mean what its name implies, that the crop by extra heat has been produced in an unusually short time, and not that it was commenced at an earlier date. Producing a crop in a shorter time is what we want, that our fruit may ripen while our days are still warm, and, what is as important, while the days are long. In Scotland, from this last cause it is thought, an average wheat crop can be grown at a lower temperature than in France, and I believe in a smaller number of days.

I had, the other day an opportunity of questioning a gentleman who had just landed from Canada upon these points, as I wished to know if he

would confirm what a friend of mine from St. Petersburg had previously told me respecting the amazingly rapid growth of all the crops. He told me that he left Montreal on the 10th of August, and that the new apples were then beginning to come into the market, though they did not consider the crop to be ripe till near the 20th of August, and that this year, which was not a late one, there was not an apple-leaf to be seen on the 20th of May. I said, "Do you say an apple crop can be perfected in three months?" He said, "Yes; you seem to overlook the length of the days, and the great heat we have—often 110° in the sun and 90° in the shade." I asked him if they found that the drainage warmed the soil and made the crops earlier; and he told me it was being largely carried on for this reason. No doubt the nature of the Canadian apples helps to explain a part of this, as all I have seen that I knew were Canadian were very light for the size. I give this for what it is worth, that it may be confirmed or disproved, but I believe it will prove to be no exaggeration. It will thus be easily seen how interested I was with this paper on "Border-heating" by the Rev. W. Kingsley; and I think he will take as much pleasure in examining these tables collected by the Royal Horticultural Society at my suggestion.

The daily history of the life of this crop of grapes is of itself a valuable paper, and I know of no treatise on the vine that contains such a one; but yet we want still more of such; and I hope next year to obtain one from a house where no heat but sun-heat can be obtained, and which yet produces yearly a very heavy crop of good grapes; but we also want, on "standard authority," the relative advantages of the different sorts of houses now built; and I venture to think that this is as much within the sphere of usefulness of the Royal Horticultural Society, as the trials of the various merits of fruit. It is said that the Council are anxious to make their garden at Chiswick as useful as their means will permit; and I believe this is true. My intention is not to raise a discussion as to whether what I propose is within their means or not, but simply as a producer of fruit I wish to obtain this knowledge, and, as I have said, I am willing to contribute towards the expense.

THE FROST AND THE ROSES.

As some of your correspondents, Mr. Editor, are favouring us with the effects of the late frost on their roses, it would I think add much to the value of their information if in addition to their showing us the hardness of a rose as compared with others of the same class, they could tell us the result of the late cold upon the same rose grown on its own roots, the manetti, or briars. As I consider every little bit of information to be of value upon this point, especially when it relates to so splendid and comparatively untried a rose as "Marchal Neil," I will give you my modicum of experience. Last spring I planted against a south wall a fair-sized plant of Marchal Neil, propagated on the manetti; it grew freely, and in the autumn flowered abundantly. About Midsummer I planted a few feet distant a second plant of the same rose—in fact, a cutting taken from the former one; it had been pushed in heat, and was at the time I turned it out of the pot a little weak wee thing, but it soon gained strength, and grew fast, until it had attained by late autumn the height of three feet. Both these plants I protected by placing before them a narrow slip of an old easement window, taking means to prevent the wet running down from the top, and leaving the sides partly open so as to admit of a current of air passing freely through. Thus protected alike, and under precisely similar circumstances as to locality, the first, viz., the parent plant on the manetti stock, succumbed completely; the cutting, which is on its own roots, is not only alive, but the eyes (which were actually green and pushing during the severity of the frost) have burst forth into vigorous young shoots; it has also retained its foliage fresh and green throughout the winter. If one can form an opinion from a single plant, I should pronounce this loveliest of all roses to be decidedly hardy when grown upon its own roots, even under the baneful influence of London smoke.

Judging, Mr. Editor, from the gloriously vigorous bushes of hybrid perpetuals I have seen growing in your garden, there seems to be no doubt of that class doing best upon their own roots in our murky atmosphere; in fact, the advantages in various ways of having our roses upon their own roots seems to me so obvious, that I cannot understand why it is that there are no nurserymen to be found who will undertake to provide us with them. I am told that the facility of propagating them on the manetti renders that method the most profitable. Granting that to be the case, I would say, get over that difficulty by charging us more. We should not grudge paying a fair percentage more for what we want, could we but depend upon obtaining them. The time required for producing a marketable sized plant by cutting is not so long as to be unremunerative either, in my opinion; for instance, cuttings I planted last September twelve months made decent-sized plants last summer, many of them flowering in the autumn. In November last I removed them to their permanent positions, and should have been well satisfied to have received similar plants from a nursery. Thus, a little over twelve months had sufficed to make cuttings of four eyes' length into established bushes, and doubtless with a nurseryman's appliances, attention, and skill, by striking from buds, the application of heat, and in various ways, time could be saved, and propagation in large quantities expedited. But even after all, if raising roses upon their own roots could not be accomplished so speedily as under the present system of grafting on the manetti, I repeat, then charge us more—only let's have them.

I believe there is a good opening and a fair field for any enterprising young man who would make it his business to carry out this method of rose propagation.

AN AMATEUR.

Stoke Newington, February 18.

[We have seen the plants mentioned in the foregoing communication. The Marchal Neil on its own roots is as lively as a bird, and as green as a willow in the month of May.—ED. G. M.]

EXHIBITIONS ANNOUNCED.—*Royal Horticultural Society*, Spring Shows, March 10th and April 16th; Great Show, June 4th to 8th; Rose Show, July 2nd; Exhibition at Bury in connection with the Royal Agricultural Society, July 15th to 19th. *Royal Botanic Society*, Spring Shows, Saturdays, March 23rd, April 13th and 27th; General Exhibitions, Wednesdays, May 29th, June 19th, July 3rd. *National Exhibition, Manchester*, June 7th to June 15th. *West of England Rose Show, Hereford*, July 9th. *Dundee Floral Fête, Baxter Park*, Sept. 4th, 5th, 6th, and 7th. *Clifton*, Spring Show, May 23rd; Rose Show, June 25th; Autumn Show, August 29th. *Leeds Horticultural Society*, Great Show, June 13th and 14. *Brussels*, April 14th, 15th, and 16th. *Malines*, March 17th, 18th, and 19th. *Paris Universal Exposition*, April 1st to October 31st.

A FEW WEEKS IN NORTH WALES.

A VISIT TO CROGEN.

The name Crogen means in English "a shell." I was assured by a friend, Mr. Strwdwick, that I should be amply paid for a journey, even if it was a long one, to behold the many elegant and various charms which surround this domain. As I had already ample cause for estimating his worth in conveying just notions of the excellences connected with natural scenery, I was of course influenced by his present advice. Moreover, he said I could review the beauties of this romantic and rugged landscape with pleasure equal to any I had derived from any of my foreign explorations, and he offered to accompany me and introduce me to the gardens at Crogen, where he is well known. I appreciated his kindness, and was glad to embrace the opportunity. We left Rhug, the abode of my friend, about ten o'clock, provided with a few of the luxuries of life. It was a clear, bright, and crisp morning; the pure air of the mountains gave a spirit and a cheerfulness to our walk. We found in our journey much to admire, particularly when the road passed over an eminence. My companion allowed very few objects of interest to escape without notice, and as we approached Crogen, the scenery became more varied and beautiful—the majestic trees that stood isolated showing all their fine proportions, and the grandeur of the woods indicating the approach of an ancestral estate. At a sudden turn of the road I came in sight of the lodge which marks the entrance to the park. As soon as I had entered, I caught a glimpse of the Hall between the trunks and branches of the trees. I found Crogen highly merited Mr. Strwdwick's description: a delightful spot, a charming retreat in the vale

from home, he has not imbibed much taste for flowers or decorative features. He had no wish to alter any untamed situation, or even attempt to invent anything where nature has been lavish of her charms. I must say, however, that here at Crogen the shrubbery was deficient of overgreens, which add so much to the coziness of a place in winter. Evergreens, indeed, seemed to be the only things wanted to give an artistic tone to the foreground of a splendid picture. There are good drives and walks, composed of stones from the river, kept clean and firm; plenty of deciduous trees and shrubs; and the disposition of the ground is naturally beautiful. I pointed this out to the gardener, and he quite agreed with me, saying that Mr. Robertson was very fond of planting, and had made new plantations to the extent of three hundred acres. The trees planted are chiefly larch and Scotch firs, and these have had a singular success; but he did not confine himself solely to those kinds, and he had no doubt that his employer would plant a few shrubs, which would add both comfort and beauty to the place. We were now conducted to the kitchen garden, which is a spacious one. There were visible signs that the gardener was well up to his work, as the gardeners say; and I think winter is the best time to tell for it, as I found here plenty of salads, such as endive, lettuces, and celery, all good—the last in particular, for I never saw better: there cannot be much room for complaint. The celery most prized was that good old variety Cole's Defiance. The brassica tribe was well represented with Brussels sprouts, broccoli, and greens of every description. The variegated kale was beautiful in its markings; they used it principally to decorate the dessert, such as apples and pears; and by-the-bye I was shown some fine specimens of Bull's Golden Reinette apple; this is a scarce variety.

THE ROBIN'S NEST IN MRS. CASH'S FERNERY.—(See page 93.)

of Ediernion, on the banks of the river Dee. The waters here are but a few yards across, gliding silently and smoothly along, reflecting the impending foliage of its banks. It is situated on the right of the turnpike road, three miles from the picturesque little village of Llanderfel. Crogen is the property of the Earl of Dudley, but the present occupant is H. Robertson, Esq., M.P. for Shrewsbury. As we traversed the carriage drive, which was in gentle sweeps through groves of majestic oaks, elms, and beeches, we saw on the left the undulated surface of the park, and on the right the high and massive rocks, their shaggy sides richly clothed with various foliage, and many diversities of colour. Conspicuous among the timber were the beeches; their trunks looked like pillars of shining marble; the white stems of the young birches, and the ragged and rufous bark of the older trees presented singular and striking contrasts. On arriving at the house, I found it a very ancient specimen of architecture. This venerable structure it is conjectured was erected prior to the sixth century. It is mantled with the "ivy green," and from the thickness of the stems it must have clung to its support for many generations, screening the walls from many mountain blasts. The walls seemed to be in a good state of preservation, and would still weather the storms for ages to come. But this mansion appears to me, from its construction, to have been of British origin; it was built, no doubt, to defend the narrow pass through the vale, a benefit which it seems capable of affording even now, though in ancient times it must have much more effectual. I was now introduced to the head gardener, Mr. Edward Jones, a Welshman of course. I soon found out that the kitchen garden was the place that received his best attention. Being a native of the mountains, perhaps never twenty miles

I once took a first prize with this sort at St. James's Hall, London. Everything looked neat and tidy, and before I left the garden I was curious enough to peep into the rhubarb and seakale pots. It was a pleasing sight; many a dish could have been cut fit to set before the Queen. We were now conducted to the best point where we could get a bird's-eye view of the place and its neighbourhood. We passed through a wood, and ascended to a promontory that jutted out above the waving branches. On reaching this elevated point, the unexpected manner in which the prospect burst into view proved the truth of all that Mr. Strwdwick had said of it. The Dee's transparent stream is seen winding elegantly in varying curves; the mountains on the opposite side of the vale are finely diversified in shape and tints; they rise in the order of an amphitheatre, and are richly covered with forest trees of gigantic size, their forms presenting every degree of grace, and where thickest affording the richest depth of shadow. The scene is that of a grand mountain forest such as I suppose Mr. Prosper is best familiar with amongst the many well-travelled men who write for the magazine. I was struck with admiration with the beauties of this situation. Right and left the vale presents a prospect of almost unequalled variety and beauty, the mansion in the midst being an object of peculiar interest in the landscape. The keeper's house, the gardener's lodge, and the labourer's cottages, all lend their aid to heighten the beauty of the scenery; for after all, much as we may talk of solitude, we do love the mingling of human life with the glories of nature. Some are rude and singularly built, and would present the young artist with good subjects for the pencil. I believe it would be difficult to find a spot that can be put in competition with it, considering it either

as the joy of a painter's eye or poet's mind, or as a desirable residence for those who admire the beautiful wildness of nature. Those who are fond of healthful exercise and recreation have here ample opportunities to gratify them, and the lovers of shooting, fishing, hunting, and boating need never lack good sport. From the various discoveries made from time to time on the spot, and in the immediate neighbourhood, of things connected with ages gone by, such as old earthenware, coins, and weapons of Roman origin, it would be an interesting place. It is, in fact, a sort of Paradise for antiquarians. In a word, so many are the delights afforded by the scenery of this place and its vicinity, that a mind imbued with any taste could not fail to be happy in it; and to the traveller who has pleasure for his object it is one of the choicest spots in Britain. If in such a spot I for once lose myself, I hope I shall be forgiven. I intended to gather a few facts for horticulturists, but how can I break a spell that is so pleasant? I am enraptured with the bold abruptness and softened swells of hill and valley. Now, as I am seated upon the brow of a projecting rock, I behold rivers, woods, and forests—the grand belts of timber ascending to the summits of the mountains, and gliding down into the embracing bosoms of the vales. How fresh, how pure, is this sweet mountain air! Let me tarry awhile and breathe a little more, while I look below upon the garden, with its trim terrace and gravel walks, and catch a glimpse of that wilderness, and the rustic borders where every sound is echoed, so that the song of a bird is like a concert, and a merry laugh has its answer still more merry from the rocks around. No; to be practical now is out of the question, and instead of prosing about plant-growing, I shall be content to say that I am happy, and that for the present my tale is done.

N. COLE.

WALKS AND DRIVES.

The walks of a garden, and especially those near the house, and much frequented in all weathers, are worthy of more attention than they generally obtain, for upon them very much of the comfort of a garden depends, especially in winter and spring, when a pleasant walk on dry, crisp, level, and nicely-moulded walks is the only outdoor garden pleasure we can take. Therefore a few hints on the subject may not be out of place at this season, when so many must experience the discomfort and inconvenience of had and shaly walks.

The first consideration is how and whence we shall obtain suitable materials. In some parts of the country there is, on or around the spot, a superabundance of material for walk making, the removal of which would improve the ground; in other parts only indifferent material can be obtained in the shape of broken stone or some kind of gravel, and that from a long distance. A thoroughly good path should be pleasant to walk upon in all weathers, but it is not always easy to find materials to form it—some walks, pleasant enough at one season, becoming rough and unpleasant after a continuation of dry weather; others sticky and unpleasant after wet and slight frost; and others, again, combining all the above-named defects. In some extensive gardens a loose gravel is preferable, which can bear a broom lightly passed over it, just to turn the stones, and then rolled to give it a level surface, but still on walking over it it seems loose. In a manufacturing district, with the atmosphere constantly charged with smoke, there is an advantage in thus turning the pebbles; it gives the walk a fresh surface, and removes the black appearance caused by the settling of the soot. As to the best colour for walks, there are various opinions, and we must regard that point as being as much a matter of taste as any other arrangement of colour—independently, of course, of the facility of obtaining the materials. In the gravel we usually obtain here the colour gradually varies from different shades of yellow to varieties of red, both of which, when very decided, are as unpleasant as a very white walk on a bright sunny day. The pebble gravel is objectionable as a rule—it does not set well, especially if under hard traffic; and walking on irregular roundish stones is anything but a luxury.

In making walks we must take into consideration the nature of the soil, for if it is of a stiff clayey nature, the water will drain into them from the sides—to some extent even if the ground has been drained, which of course should be the first proceeding in making a garden. But we often find ground drained in patches—an expensive and unwise mode, which has to be supplemented if any slight alteration has to be made in the walks; so that the first thing is to see that there are proper outlets for the water to pass off quickly, if possible by drains independent of those in the surrounding grounds. Among the reasons for separate outfalls for the surface water are these—it is expected to pass from the walk at once, the drains are more likely to get choked with gravel, leaves, &c., and it is not necessary to place them as low as would generally be the case in draining the soil.

In walks from 4 feet to 6 feet wide, one drain is sufficient, which I would place at one side of the walk, giving it a slight fall from the opposite side, under the walk-making material. For a walk of these widths 4-inch drain-tiles would be large enough, with grates at sufficient distance to keep water from standing, or the walk from washing by the running of a heavy shower—which the nature of the ground would at once decide; if it were a binding gravel from which the water all ran off, it would require more grates than a loose one through which most of the rain filtered at once into the drainage material under. For the narrow walks I should use about six inches of rough stones, and if a loose gravel, a coat of rough gravel, finishing off with a thin coat of fine gravel, which, when well rolled, would give a thickness of about three inches of gravel. If stone be scarce and brick rubbish plentiful, that may be employed. Some of the best walks in the London parks are made of brick rubbish, surfaced with a few inches of yellow gravel, and then thinly sprinkled with fine shell gravel brought from the seashore. Where sand is abundant, but of a character that does not bind, it may be induced to do so by being mixed with about one-fifth of loam, which will cause it to bind well after being well rolled.

In making walks of from 16 feet to 20 feet wide, we should require extra drainage. It would be then necessary to have two drains, and also to have an additional thickness of stones or other rough material as a foundation.

In the making of carriage drives, the earth should be taken out to a depth of about 16 inches at the sides and 12 inches or so in the centre, with a 4-inch drain at one side, and gratings at from 40 feet to 60 feet apart to take away the surface water—gratings at each side of the walk, observe—those on one side communicating with the drain on the opposite side by pipes across the walk. Under each grating should be a bricked pit or "lodge," to catch the sediment of gravel which rushes off so much with heavy rains and showers; and these little pitfalls should be occasionally emptied. These pits should sink a foot or more lower than the drain pipe. Then over the whole surface of the drive should be placed rough stones or brick rubbish to the depth of 8 inches or 10 inches; over that a couple of inches of stone,

broken small, and, finally, 3 inches of gravel placed on the surface and rolled down till it becomes quite solid. The carriage road should be 3 inches higher at the centre than the sides.

The plan described for the making of carriage drives will do equally well for the chief garden walks, only that the excavation need not be so deep by 6 inches, and the several layers of stones or brick rubbish and gravel may be proportionately thinner and smaller.

Walks should not be round or high in the centre, as they are then very unpleasant to walk upon, although there must be a slope to the sides for the escape of water, but we often see a very unnecessary fall, which in all cases should be avoided, and of course the more soil the material the less fall is required. A slope from the centre to the sides, so gentle that it may be perceived by the eye, but not be sensible to the foot, is the happy medium.

There is generally the pest of weeds on gravel walks—in some sorts of gravel more than others. Our gravel being the waste from lead works, we have not so much of that; and I believe when walks are made from the refuse from copper works weeds are still less troublesome.

We still occasionally see walks turned over with the spade and also the hoe in the sun, but that is almost a thing of the past, and a few hundred-weights of salt would not only save the labour, but keep the walks in good condition with an occasional rolling.

Asphalte walks are very good when well made, but if badly done they soon prove a thorough nuisance, from the tar melting in summer and the repulsive odour; and with hard wear they soon get into holes, which are only receptacles for water, and cannot be repaired satisfactorily; yet with general garden traffic, and in places where there is a difficulty in obtaining good gravel, asphaltic is preferable to the very rough and slovenly paths called "walks" seen in some gardens.

In the making of asphaltic walks too much tar is often used, which, while rendering them a nuisance, by no means adds to their wear or utility. The fall from the centre of an asphaltic walk should be slightly less than in the case of gravel walks; the grates for drains must be at a little less distance, for of course all the water has to be carried off an asphaltic walk, whereas in a gravel one, no matter how firm, it soaks in to some extent. The foundation of the walk should be made in precisely the same way, but every part should be rammed more thoroughly solid in the case of an asphaltic walk, leaving space, after all is finished, for one inch of asphaltic. What we use here is composed of three parts coal ashes, sifted through a half-inch sieve, and one part gas lime. The gas lime may be dispensed with if not readily obtainable, and the four parts of ashes used mixed with sufficient gas tar to moisten the whole mass without saturating it. The tar should be used in a hoiling state, and the ashes should be tolerably dry, for they are only mix better, but less tar is required, and the less the better. Great care should be taken to mix it thoroughly without using too much. The whole should be well mixed and laid in a heap under cover a few days previous to being laid down. In depositing, of course a favourable state of the weather should be chosen. After it has been laid quite level, it will require three or four rollings to make it quite solid. But previous to rolling it should be thoroughly levelled and sprinkled with any gravel that may be considered best in colour and texture. Here we use the white spar gravel, and put as much on thinly and evenly as almost to obscure the asphaltic, and give us a nearly white walk. In many places this white spar gravel is not to be obtained, and other convenient gravel must be used. But it must be sifted fine so as to form a crisp surface that will not loosen; let no large pebbles go in, or the thing will be injured thereby, as if dislodged by any means holes remain. The advantages of these walks are that we may employ very useless rubbish in making them, and a mere sprinkling of gravel makes the walk look as well as if three inches were deposited on it. Frost does not affect them if well made; weeds are entirely shut out; and after heavy rain or showers they dry immediately. They are, therefore, particularly well suited to the immediate neighbourhood of the house or out-offices, or any positions liable to be much traversed in all sorts of weather and seasons; and for the floors of sheds and such structures there is nothing to equal asphaltic or concrete. It is impossible, however, to entirely do away with the smell of the tar in hot weather.

The cement concrete walk is made by taking out six inches of soil at the sides and four at the centre, to cause a fall from centre to sides, and the bottom should be made perfectly firm with any rough refuse material convenient to hand—stones, lime rubbish, clinkers, &c., mixing with these one-sixth of fresh lime, and filling in to the depth of four inches and a half. For the remainder, mix one part of good Portland cement to six of finely-broken stones, and lay this over the surface an inch and a half thick, making it perfectly level with a very slight fall from the centre to the sides.

JAMES TAPLING, in "The Field."

VARIEGATED CUPRESSUS MACROCARPA.

The subject of sports in plants, incidentally alluded to last week, reminds us of bringing under the notice of our readers a very remarkable, and if permanently "fixed," a very valuable sport from the beautiful Californian Cypress, *Cupressus macrocarpa*, which we noticed on the occasion of a visit to Mr. Niven's interesting nursery at Drumcondra, some weeks since. Few, if indeed any, of the division of the invaluable tribe to which it belongs are more ornamental, or destined to add a more striking feature to park or other scenery, even in its normal colour, than this. Its perfect hardness, rapidity of growth, imposing appearance, and the readiness and advantage with which it submits and accommodates itself to the pruning knife, whenever the use of the latter is desirable or necessary, are further recommendations in its favour. Beautiful, indeed, as it is in the simplicity of its bright, cheerful green, will not a new feature of interest be added if its rich verdure can be splashed with blotches of more than pearly whiteness? Such as this is the variety or sport which Mr. Niven has been fortunate enough to secure. On a handsome tree, of the normal type, in his grounds, he observed one or more branchlets coming beautifully and strikingly variegated; with his usual acuteness and decision, he set about propagating it, and at the time of our visit we noticed several nice little specimens under bell-glasses, worked, we believe, but are not quite sure, on stocks of the original variety. As seen beneath the protecting glasses, the variegation appeared to be very pure and decided, and looked to great advantage. It is not a sickly-looking pallor over the whole plant, like that of the variegated *Wellingtonia*, but a combination of the richest green blotched with the purest white. Should it be constant, as we have no reason to doubt but it will, how effective will it be, either standing singly or grouped with its fellows. Of course, it will be a little time before Mr. Niven will have multiplied his stock to such an extent as to allow of its being sent out, but when he does it will, as a matter of course, be eagerly sought after, and the stock speedily cleared out at a considerable figure.—*Irish Farmer's Gazette*.

Calendar.

WORK FOR WEEK COMMENCING MARCH 2.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—Get manure on to the plots that are to be sown or planted this month and next, and dig the ground over deeply, and leave rough. Level down the ridges of ground prepared last month, so as to be ready to sow and plant as soon as weather permits. Plant the main crop of potatoes where the ground is well drained at once, but on damp soils wait till next month. It is not safe to manure for potatoes, but charred rubbish, old mortar, and other dry materials may be used to lighten the soil and nourish the crop. For main crops choose a plot that was well manured last year; for early sorts that are to come up before the autumn rains set in, manure may be dug into the trenches. Potatoes are best planted in trenches, and covered loosely with soil; dibbling is apt to cause rotting by the holes getting filled with water. Horseradish may be planted in any spare corner, but the ground should be dug deeply, and the roots will come finer if the subsoil is well manured. The crowns should be planted fifteen inches deep, and six inches apart every way, and the holes filled with fine coal-ashes, or the sets put in as the trenching proceeds. Any part of the root will do as well as the crowns, if cut into inch pieces. Mark out onion beds, and let the soil be liberally manured. Get ready for all successional summer crops, so as to have the ground firm and well sweetened in time to receive them. Sow turnip, long radish, main crop of parsnips, horn carrot, cauliflower, cabbage, savoys, broccoli, main crop of onions, peas for succession, lettuce of all kinds, round spinach, parsley, and small salads.

BROCCOLI for autumn use to be sown in small quantities this week and next. Early White, Walcheren, and Purple Sprouting will give a good succession.

CAULIFLOWERS will be growing as soon as the weather is milder. Give air by tilting the lights, and let them have warm showers; but cover up at night in case of frost.

SPINACH to be sown in successive breadths between rows of peas. This crop is apt to come in a glut, and this should be guarded against by sowing only a sufficient breadth at one time for a fair supply. Where there is plenty of room, New Zealand spinach may be sown in heat for planting out; a dozen plants will be enough for his family.

Flower Garden.

FLOWER GARDEN.—Lightly fork the borders, so as not to injure the roots of herbaceous plants, and make the surface moderately fine, to give a neat appearance. Sow hardy annuals in the borders, and put a tally to each patch; as soon as large enough to handle, thin the patches, and plant out the thinnings wherever required; or pot them for blooming in the windows. Put stakes to newly-planted roses and other trees, and mulch beds of roses to protect their roots from dry bleak winds.

GERANIUMS that have been kept in pits, windows, and cool houses, in a rather dry state, now require pruning and a little water. If they can be put in a warm house, to give them a start, they will bloom earlier. Those that are to be flowered in pots require a shift; those that are to be turned out into beds may remain in pots as they are.

HERBACEOUS PLANTS.—Continue to divide and plant the borders. The early-blooming kinds are now coming into flower, and may be propagated from cuttings as soon as the bloom is over.

PANSIES to be pegged out in the style of Verbenas, so as to display their blooms over a large surface, and root if they please at every joint. For those who use Pansies in beds and front lines, Magpie and Trentham Blue are two very valuable kinds; but they are not show flowers. Sow now to bloom during the summer.

PROPAGATING to be carried on with spirit, that the bedding and other summer stock may be strong when required to be turned out. Sow in heat *Brachycoma*, *Phlox*, *Portulacca*, *Schizanthus*, *Stock*, *Cockscomb*, *Globe Amaranth*, *Balsam*, *Zinnia*, &c. Fine plants for bloom this season may be had by putting in cuttings now of *Fuchsia*, *Geranium*, *Salvia*, *Heliotrope*, *Verbena*, *Petunia*, &c. Those struck early will now require stopping and shifting. Always stop first, and wait a week to shift.

AURICULAS.—These will require frequent watering and plenty of air, but must be sheltered from cutting winds. Weak liquid manure will strengthen the trusses. Green-fly will appear as the plants make their new growth, and must be promptly met by means of tobacco-smoke. *Polyanthuses* the same treatment.

CARNATIONS AND PICOTEES.—Clean up the plants, and wash the outside of the pots. Make ready for potting in the second week of the month, and search the compost well for vermin, or much mischief may ensue.

HOLLYHOCKS not yet planted out must be hardened by free exposure to the air, but protected from severe frosts and storms. Those already hardened should be planted without delay, and stakes placed for them at once, as driving the stake down hereafter will do injury to the roots.

TULIPS must be kept hardy by free exposure, but severe frosts, especially after rain, will do them much harm. Protect, therefore, as occasion may require, but be careful not to retain the coverings one hour after the change of weather has rendered them unnecessary.

Fruit Garden and Orchard House.

FRUIT GARDEN.—Mulch raspberries with four inches of half-rotten dung; the ground between them must never be dug, not even with a fork. Trees newly planted to be securely staked, and in dry soils it will be as well to mulch their roots. Finish pruning and nailing, have ready calico, netting, or whatever else is used for protecting wall trees which will be in bloom early this year. Lay down plenty of rotten dung between strawberry-beds. All kinds of fruit-trees and fruit-bushes may yet be planted, though it is full late.

WALL FRUITS are now pushing into bloom, and protecting material should be put up at once if not done already. We use Haythorn's hexagon netting, and find the large meshes as effectual as the small, and the price is considerably lower. Beware of coddling the trees by means of shelter; sunshine and air are beneficial—frost and rain do the mischief; a breeze playing among the blossoms helps to set the pollen.

VINEYARD GRAPES FOR ENGLISH WINES.—Those who have suitable walls, and who wish for good home-made wine, will do well to appropriate their walls to such varieties as are most suitable, as there will be a greater certainty of the grapes being well ripened than by open vineyard culture.

But in spots moderately sheltered, and enjoying what may be understood as an average good climate, open vineyard culture will answer well, and is at once the simplest and cheapest mode of producing grapes for wine. The vines may be planted out in rows six feet apart every way, which will allow of a free circulation of air amongst them, and enable the cultivator to move amongst them freely. If land is expensive or limited in extent, some useful crops of summer vegetables may be grown between the rows, or the rows may be put at four feet apart, and if they run east and west they will not much shade each other. But in any case the vines must be six feet apart in the row, because of the system of cultivation to be followed. This, of course, will be what is termed the "long-rod system." But there is a right and a wrong way of doing it, and the wisest course to follow will be to cut the vines down to four or five buds after they have been planted one year. Four strong shoots are to be allowed to grow, and all others are to be suppressed. These should be trained out sufficiently apart that their leaves do not overlap, but as nearly upright as possible, and they are to grow as long as they please—that is to say, they are not to be pinched or pruned during the whole of the season. In the winter they are to be pruned to three, four, or five feet lengths, and the length of each rod must be determined by its degree of ripeness. Better cut them back to one foot, and have hard, brown wood, and plump, well-ripened buds, than allow any length of soft, greenish, or slender wood to remain for fruit bearing. When pruned, these ripe rods are to be trained down horizontal within a foot or so of the ground. They must be kept sufficiently far apart that their leaves do not overlap, and the rule must be to bring them as low and as nearly horizontal as possible. Sometimes the vine will not produce fine canes to take the place of those tied down; in such a case it may be advisable to allow some of the old canes to remain until there are suitable canes to replace them, thus allowing them to fruit a second or a third time, as they will do. This would be called a combination of long-rod and spur pruning, a combination by no means desirable, and only to be adopted when, by a shyness of growth or any accident to a particular vine, there happens not to be at the end of the season canes suitable for the next year's use.

SELECTION OF GRAPES FOR ENGLISH VINEYARDS.—The very best varieties for the purpose are the following. *Royal Muscadine*: There are several varieties in cultivation under this name; the proper one for wine-making produces a round berry of medium size; the bunch is broadly shouldered, the leaves are roundish, and die off in autumn a bright yellow colour. *Miller's Burgundy*, which is not useless if unripe, but will generally ripen well if grown in a sunny spot, even if the season is not so good as the average. *Claret*: The best wine grape known; it is the kind generally grown in the south of France, and produces the real Bordeaux, which is the best of all wines, though not in high repute in this country; rather tender in constitution, and needs a dry soil and a good climate to do well. The four which follow require a warm soil and a good climate. *Cambridge Botanic Garden*: Of no use for the wine-press, except to mix with others. *Early Black Bordeaux*: Flesh melting, and very rich, hardy, and early. *Macready's Early White*: Well adapted to make a light still wine, if sided with sugar. *July Cluster*: Pretty sure always to ripen on stakes, and useful to mix for wine-making, to give richness and colour.

Greenhouse and Conservatory.

CONSERVATORY to be kept as much as possible without fire-heat, as the natural temperature will now be high enough for most of the forced flowers, such as *Cinerarias*, *Cytisus*, *Deutzia*, &c., and they will last longer than with heat. But as frosts often occur at this season, with cutting east winds, a fire may be occasionally needful, in which case get it up without delay, for many of the subjects in bloom now are of a delicate nature, and climbers growing on pillars and rafters will suffer much if chilled. To keep the conservatory gay, put *Roses*, *Rhododendrons*, *Azaleas*, and early *Pelargoniums* into a moderate warmth, to bring them into bloom. Give plenty of water and liquid manure to plants coming into bloom, especially *Americans*, *Camellias*, *Pelargoniums*, and *Acacias*. Plants done blooming should be tended with care to secure a healthy growth of new wood, and be cut in if required before they spend their strength at the ends of flowering shoots. Give plenty of air, and increase the heat in all plant-houses. Use the syringe freely, to keep a clean foliage; repot any plants that want more root-room; see to the training of greenhouse and conservatory climbers before they get into too free a growth to be handled conveniently.

CALCEOLARIAS may be struck in any quantity for blooming this season; a very slight heat is sufficient. Use young, tender shoots, and root them in sandy peat. Specimen plants for early blooming will come on nicely along with *Americans* and other plants that like moisture; but they must be in the coolest and airiest part of the house, for much heat is an injury to them. Give liquid manure once a week.

CINERARIAS must have plenty of light and air, and all superfluous shoots and injured leaves should be cut clean away. A cool shelf near the glass is the best place for them; and they must be watched that green-fly does not take complete possession of their succulent foliage.

DAHLIAS should be got to work without delay. Divide the old roots, one eye to each piece, and pot in light, rich loam, and plunge the pots in a warm pit on the tank of a propagating-house. Those started last month may be propagated by cuttings, if stock runs short; the cuttings must be taken under a joint, and rooted in thumbs filed with poor sandy loam, to be shifted in rich light soil as soon as rooted.

REPOTTING VARIEGATED BEGONIAS.—A rich, light soil suits them all alike; none of them are peculiar in that respect. The soil we use is a mixture of fresh turfy peat chopped to the size of eggs, leaf-mould thoroughly rotted and well frosted, fibrous loam, and sharp sand, equal parts. If the peat is poor in fibre, we add a half part of old cow-dung, but with first-rate peat and loam we prefer to do without the dung, except it be for top-dressing plants intended for large specimens. About the middle of February, and thence on to the middle of March, they should be shaken out of their pots, all the old soil removed, but with care not to injure roots or tubers, and repotted, with the crown of the plant level with the surface of the soil. They should be potted firm, and it would be well to sift the soil, so as to remove from it all the fine stuff, for they grow best in lumpy, elastic compost, the materials of which are well incorporated; the sifting should be done before adding the sand. After repotting, they should be placed in a moist brisk heat, and there is nothing to equal for this purpose a sweet hotbed. Wanting this, a tan-bed or pine-pit will do, but the plunging material must be kept very moist, and the plants have but little water until growth has fairly commenced. Any excess of

water at this stage would cause them to rot at the collar; but when in full growth they should have plenty. The cultivator will have to guard against giving too much air, admitting too much light, and above all against wotting the leaves. A few waterings overhead will soon spoil the finest lot of begonias ever raised, and those that escape utter ruin will be denuded of their exquisite beauty. In furnishing a conservatory with them, therefore, take care not to admit any cold draughts, and see that the shading is in its place before removing the plants from the stove. Many a disappointment has occurred through neglect of these precautions.

PROPAGATION OF BEGONIAS.—It is nothing new now to talk about propagating plants from leaves. Prepare a good sweet, moist hothed; take off a complete leaf, and lay it on the bed, and it will root in a few days. Or to do the work in a more wholesale way, incise the leaf across each of the principal veins, and it will at once produce a number of young plants, which are to be potted in thumb-pots, as soon as fairly rooted in rather fine turfy peat and sand only. Some of them may be increased by cutting the leaves in small pieces, and pressing the cut edge of each piece gently on the surface of the bed. In propagating-houses we generally see begonia leaves at work under bell-glasses, and at a tremendous temperature. There is no need of either; a sweet dung-hed in full play will cause the formation of roots almost immediately; and there is no need of bell-glasses, unless the hed is exposed to draughts of cold air, a supposition almost needless. Where a sweet hothed is not at hand for leaf propagation, it is advisable to insert them in pots. Choose for the purpose leaves half-grown, cut off the leaf with a sharp knife close to the stem; keep it shaded for a short while, but so that the cut end will dry before planting it. Prepare five-inch pots with half drainage, and the rest sandy peat with an inch of clean sand on the top. Insert the leaves close to the side of the pot, and if they fall over towards the centre, place a short stick there to support them. Water liberally, and place at once in a close moist heat. If the air is not moist, they must be covered with bell-glasses; they must be shaded from sun, and will soon form plants.

PELARGONIUMS must be stopped where the growth is irregular, and tied out to good shapes for blooming. Give more heat and more water as the days lengthen; plenty of light, and manure-water once a week. The syringe and the fumigator must both be kept in action to keep vermin in check. Scarce kinds of Pelargoniums may now be propagated from pieces of the roots put into small pots, leaving the top just visible; they must be in a moist heat, and shaded till they show shoots. Specimens now showing their trusses will need a little manure-water occasionally, and occasional syringing. Plants lately potted to be stopped as soon as their new growth admits of it, or they will soon become leggy.

AZALEAS out of bloom must be encouraged to grow by being kept rather close and moist. Young plants being pushed on for specimens should now be repotted, and the compost should be as firm as it is safe to use; that is to say, instead of light, poor, sandy peat alone, let them have a fair allowance of mellow silky loam, in order to get a short, stout growth, and a robust constitution.

ERICAS will in many cases need repotting, which attend to. Plenty of siliceous grit is essential to their well-doing. In selecting peat for these, always give the preference to that which is full of fibre, and which is tough in breaking. Powdery soil which goes to dust at a touch is of a starving nature, and will cause a stunted growth and a poverty of bloom. Be particularly careful about the drainage, and see that the ball of roots is quite moist before planting it in the new pot.

Stove and Orchid House.

ORCHID HOUSE.—Many of the subjects in this house will now be coming into growth, but must not for that reason be stimulated too suddenly by any undue rise of temperature. There are very few that will require more than a temperature of 65° as a maximum, and 55° minimum, and the amateur cultivator is advised to keep to this moderate range as much safer than higher temperature at this time of year; but as the month advances the midday temperature may be allowed to rise to 70°. Growing plants will want water, and this will be best administered by dipping, so as to thoroughly wet the roots, and without suffering a drop of water to lodge among the leaves or huls. Those that want a shift to have it as soon as they show signs of being really on the move. All that are suitable to grow on logs or in baskets should be so planted, as far preferable to pots. *Aerides*, *Vandas*, *Saccolabiums*, *Phalenopsis*, and *Zygopetalums* need now the warmest end of the house, as they are in free growth. Care must be taken not to wet their young shoots. *Cyrtopodiums*, *Barkerias*, *Cycnoches*, *Phajus albus*, and *Wallichiana* to be watered with very great care, and with due regard to their condition as to growth, as while they are quite at rest they must be kept rather dry. On bright days water the floor of the house freely. In neglected houses there is at this time of year much injury caused by rot and spot. In the case of the first, cut away the part affected, and fill up the wound with silver-sand or sulphur. Spot is the result of a sappy condition of the plants, and where there is much of it, the only safe course is to increase the temperature and encourage a vigorous growth as early as possible, and the plants will outgrow it; it is invariably the result of excessive moisture in winter, or of cold draughts, or of steam followed by a low temperature. The month of March is the best time for a general repotting of plants that require a shift and propagating by dividing the pseudo-bulbs. By a decisive cut with a sharp knife between the pseudo-hulbs, *Dendrobium* may be multiplied with the greatest certainty, in much the same way as taking offsets from *Auriculas*, the cuttings being preferable if they have each a few roots attached. These are to be potted and placed in a shady part of the house, and to have extra warmth and very little water till they begin to grow. Old flowering bulbs of *D. nobile*, *pulchellum*, &c., may be cut away without roots, and if laid on damp moss in a close part of the house will soon emit roots, and may then be potted. At the beginning of the month is the best time to repot *Anæctochili*; and as these have no fleshy hulbs, great care must be taken as to watering, or they may rot away at the collar. But beware of keeping *Anæctochili* too dry from this time to the end of September. Plants in a thriving condition will require plenty of water, and always a little air, as they are coming into active growth for the season. The soil for them should be chopped sphagnum two parts, and with one part of fibrous peat and silver-sand.—Orchids that may be in bloom in March: *Dendrobium nobile*, *pulchellum*, *maorophyllum*, *densiflorum*, *Farmeri*, *Pierardi latifolium*, *aggregatum majus*, *anosmum*, *Cambridgeanum*, *fimbriatum oculatum*, *litiflorum*, *nobile intermedium*, *nobile pendulum*; *Bletia patula*; *Brassavola glauca*; *Cattleya amethystoglossa*, *Mossii*, *Skinneri*; *Cœlogyno cristata*; *Cymbidium eburneum*; *Cypripedium*

hiflora, *caudatum*, *caudatum roseum*, *hirsutissimum*; *Epidendron aurantiacum*, *crassifolium*, *Hambarganum*; *Jycaste cruenta*, *Deppi*; *Oncidium sacodes*, *sessile*; *Phajus Wallichii*, *Phalenopsis amabilis*, *grandiflora*; *Saccolabium miniatum*; *Trichopilia suavis*.

BEDDING PLANTS to be shifted on as fast as possible. Soft-wooded plants required to grow quick, to be potted in compost consisting chiefly of leaf-mould and very rotten dung, and the stuff pressed into the pots rather lightly. Plants for specimens should always have a compost in which sound turfy loam predominates, and be potted firm.

BEGONIAS not yet potted must have attention at once. They delight in a fresh soil, without manure; and if a mixture has to be prepared, it should be equal parts turfy peat, loam, and leaf-mould. Give them a warm moist place after the shift, and be very careful to secure them against any drip of moisture on the leaves.

GLOXINIAS may be started in a good dung heat as easily as in the stove. Losses often occur at this season through careless ways of starting Gloxinias. The soil should be equal parts fibry peat, turfy loam, leaf-mould, and silver-sand. There are some loams and some peats that grow them to perfection without any admixture of other materials. When the pans are filled, the hulbs should be pressed down on the surface, and left uncovered and without water; there will be sufficient moisture in the soil to start them. Place them in a moist heat of 70°, and when they have made a little progress remove to a temperature of 60°, and give water in plenty as they advance in growth.

STOVE PLANTS.—Continue to shift and repot as required. Nearly every plant in the house will need some attention of the kind, either to give more root-room or to refresh with new compost. As the season is advancing, all arrears should be completed quickly. Plants with variegated leaves usually do best in fresh compost of a rather poor nature; stimulating substances, such as rotten dung, frequently drive out the variegation, and restore the plant to a normal condition. When variegated plants require extra nourishment, it is best accomplished by potting in turfy loam and good leaf-mould. *Rondeletias* to be cut in and started. Plants that have done blooming require attention, first to be cut down and set aside for three or four weeks, then to be repotted. When repotted, place over hottom-heat, and give little water at the root, with frequent light sprinklings overhead, until they make a start; then water liberally.

STOVE CLIMBERS ought to grow freely now, or it is impossible they can bloom well. Push on *Allamandas*, *Dipladenias*, *Clerodendrons*, *Stephanotis*, *Hoya*, &c., &c., but do not tie them in hard until they have made some progress, for tying checks growth, and hastens flowering. Bottom-heat will do wonders for all these things now.

Forcing Pit.

FORCING.—A temperature of 50° night, and 60° day, will bring on *Roses*, *Daphnes*, *Lilacs*, *Weigelias*, *Kalmias*, *Azaleas*, double *Plum*, *Almond*, and *Peach*, and other of the showy spring flowers, with very little trouble. Keep a moist air, and beware of crowding.

STRAWBERRIES under glass will require liquid manure, plenty of air, and to be kept near the glass. Thin the fruit and blossoms as soon as a moderate number are set on each plant.

CHERRIES in the forcing-house are looking brilliant this season, the trees being in good health and loaded with fruit. While north-east winds prevail, as they are likely to now for some time, be careful in giving air, so as not to expose them to killing draughts. But air they must have in plenty, and water too overhead and at the root, except when they are in bloom, when it is desirable to keep them rather dry.

MELONS are now being hedged out for the summer crop, and it is well to be thus early, so as to derive the fullest possible advantage from sun-heat. To do them well requires a constant heat, and if from fermenting materials all the better; in fact, there is nothing to equal dung beds for melons and cucumbers. This is not said to disparage hot water, for that is safe and certain; but where manure is plentiful, and there is sufficient skill and labour to manage dung beds well, cucumbers and melons are sure to be well grown. One of the first essentials in making up a bed is to have plenty of material; small quantities are of no use at all. A strong, steady, but quite sweet heat is needed, and this can only be obtained by working the manure sufficiently, and no more than sufficient, and making it up at least with a sufficient degree of moisture to maintain the fermentation. As for soil, a good strong maiden loam full of grass fibre is the best. Clay will grow melons well; light soils are of little use, and manure is not at all desirable.

PEACHES.—The principal work now consists of disbudbing, thinning, and training in; all these operations should be carried on in a systematic manner, and the trees should have daily attention. The cautious peach-grower will now open the border in one or two places to see how it is as to moisture; it may be very wet or very dry at a few inches below the surface. A medium state of moisture is essential to the growth of the crop, and all excess ought to pass away readily. The early house should range from 50° to 85°, these being the utmost extremes allowable; a good average is 55° night, 65° day. No harm at all in going down to 50° at night, even after bright days, and much better indeed for the trees than keeping them a few degrees too warm at night.

PINES swelling fruit must have abundance of moisture, and a day temperature of 75° to 85°; night, 60°. Young plants recently potted must be encouraged to make new roots; and if very bright sunshine, with east winds, give shade, and be cautious about ventilating.

VINES.—At this time of year some cultivators tie up the stems of vines in haybands, and keep the bandages damp with the syringe, in order to induce the formation of a mass of roots. This is bad practice; all aerial roots are objectionable, except in the case of plants which naturally live by such roots—as certain orchids, for instance. One consideration is alone sufficient to show the folly of inducing the formation of such roots; they are liable at any time to perish through being allowed to go dry, or through small changes in the arrangement of the house, &c., &c., and the sudden loss of their contributions may cripple a whole crop of grapes at the most critical period, when perhaps they are half swelled. Our advice is never encourage these roots on the stems; to prevent them is not always possible, especially when the stems pass near water. Vines not started must be pruned and dressed without further delay.

CUCUMBERS coming into bearing to have the fruit blossoms impregnated at midday, and the fruit to be constantly thinned. Stop and train regularly. Sprinkle warm water over the bed before shutting up, and shut up at 75° or 80°, which will cool to 60° by the morning.

THE WINTER AND THE ROSES.

In the number for February 9 of the GARDENER'S MAGAZINE, there is a very useful paper from a Yorkshire rosarian, recording the effects of the winter on certain varieties of roses in his locality, inasmuch as it illustrates the necessity of a wide field of induction before attempts are made to determine general principles or rules. There are so many circumstances and conditions to be taken into consideration before pronouncing any given varieties hardy or the reverse, that we ought not to take any single season, even though exceptional, as a test upon that important point, although there are some kinds that experience has proved capable of withstanding the rigour of any winter we are likely to have in this island. One of the circumstances, too often lost sight of, which determines the power of any plant to resist unusual severity in the weather is the state of growth in which it is when attacked by frost. Thus it will be found that many worked roses have been seriously injured or destroyed which would have passed through the winter unharmed had the wood been well ripened during the autumn, instead of which, even after Christmas, they were in a pushing state, the branches full of sap—hence their destruction.

The climate on the north-east side of London does not err on the side of mildness, and it is in an exposed district my observations have been made. Proceeding to join friendly issue with your Yorkshire correspondent, it will be necessary first to notice his opinion that "none of the perpetuals are safe under a zeroic frost." This my observation convinces me must not be laid down as an absolute law. I have now several bushes and standards which withstood the terrific winter of 1860, some of the varieties being among those which he classes among the tender kinds—Madame Knorr, Madame Rivers, Chabriland, Anna Alexieff, Comte de Nanteuil, Louise Peyronny. All of these, with many others named as half-hardy only, have received no injury to speak of here; yet my little plot on the side of London is in a very bleak position, and the north and north-east winds, in particular, career over it as a Derby crack sweeps over Epsom Downs—nor are there any high walls or fences to break their force. As to some of the branches of certain sorts being touched, this will always be the case: probably the kinds selected as the hardiest this season would exhibit the same appearance themselves another year. It is quite a new defect in Jacqueminot to exhibit tenderness. Admiral Nelson, Prince Camille de Rohan, Le Rbone, Senateur Vaisse, Francois Lacharme, again, are certainly as hardy as most roses known. Some other reason, therefore, than the natural constitution of varieties must be sought for to reconcile these discrepancies, and this will probably be found in the situation of Mr. Taylor's rosery, viz., in a valley, roses being much more likely to fall victims to atmospheric severities upon low grounds than high, even if not so much exposed.

As an illustration of the eccentricity with which roses will sometimes behave, I have a small plant of Monte Christo, on a 6-inch brier of diminutive thickness. This was one of the French stocks sent over during its season to Mr. J. Fraser; and after being cut up for propagating purposes, it came to me for experiment. This was planted by the ignoramus who moved my roses as deeply as a manetti, and consequently it ought to have died. Nevertheless it gave me several blooms last year, upon stems about the substance of a crow-quill, and it is now pushing vigorously, as if there had been no such thing as frost. How is this to be accounted for, setting aside as it does generally accepted principles?

A list is here appended of such as have proved themselves quite hardy here, for the sake of comparison, as among them will be found some which appear to have behaved very differently with your correspondent. Anna Alexieff, Baronne Prevost, Charles Lefebvre ("as hard as iron"), Caroline de Sansalles, Centifolia Rosea, Comtesse de Kergolay, Chabriland, Comte de Nanteuil, Duchesse de Morny, Duchesse d'Orleans, Duke of Wellington, Duc de Rohan (my plants were shaky), Duc de Cazes, F. Lacharme, General Jacqueminot, General Washington, Gloire de Santhey (it is quite unnecessary to grow this variety), Jules Margottin, Jacques Lafitte, Jean Bart, Jean Goujon, John Hopper (how English-like in its robustness!), La Brillante, La Tour de Crouy and Louise Peyronny (not quite in such good condition as the rest), Lord Raglan, Lafontaine, Le Rbone, Madame Bruni, Madame Boutin, Marschal Forey (not worth a place in any garden except for a stock to bud on), Clemence Joigneaux, Cambaceres, Domage, Madame Victor Verdier, (a companion to Lefebvre and John Hopper), Madame Knorr, Mrs. Rivers, Madame Freeman (mine doubtful), M. Montigny, Paul de la Meillereze, Pauline Lanzezeur, Pierre Notting, Pius IX., Princess of Wales, Terre Noir, Triomphe des Beaux Arts, Senateur Vaisse, Vicomte Vigier, Triomphe de Caen, Victor Verdier, William Griffiths. Bourbons, Catherine Guillot, Emotion (particularly hardy), H. Dombrain, Victor Emmanuel. All these are freely sprouting, as if there had never been any frost at all.

My experience of the Teas is so contrary to what I hear, that it cannot be taken as a criterion of anything more than to show how little protection will suffice to preserve them if upon their own roots; or upon the manetti. And here to digress a moment: a manetti properly planted is equivalent to a rose on its own roots, and quickly becomes transformed to such, so that at the season it may be taken up and sometimes part of the plant with a huge bunch of fibres removed (I have several plants procured in that manner), or the manetti stock itself may be cut away. Indeed I always provide for this possibility by placing a handful of soft fine soil round the work of manettis at the time of planting. The prevalence of suckers arises from the lower eyes not being properly removed at the last planting previous to budding. It must be confessed the frost caught me entirely unprepared—indeed as my collection is chiefly for experiment, newer kinds are usually left to themselves; there were a few favourite teas, however, which I did not wish to lose. Unfortunately, they were left unprotected till it was too late, and I gave them up for lost. However I went to look at them before the snow had disappeared, and found them all green enough about the collar. I got some old flower-pots, and broke them up—for no other protecting medium was at hand—placed a few of them over each of the plants, and I now find them starting into growth below the branches killed back, like the rest of their neighbours. They were—hear it with astonishment!—Madame Falcot, Souvenir d'un Ami, Melanie Willermoz, Devoniensis, Climbing Devoniensis, Napoleon, and Triomphe de Guillot Fils.

Of course the most interesting of tender roses at this time is the beautiful Marechal Niel. The reports that have yet reached me of its sufferings from the frost are melancholy in the extreme,—killed—dead—dying,—such appears the general verdict; plants and dormant buds are included in the same category. I have but two plants yet of this variety, a standard and a dwarf, on the manetti. Both are alive, without the least protection—cut

back, it is true, but still unslaughtered. Here, then, is a case opposed to general facts. I have no doubt others will be recorded; and it behoves us to ponder well over such contrarieties, and to ponder ere we lay down conclusions which further experience may explode as fallacies. The Marechal requires further trial. Narcisso is entirely killed; Gloire de Dijon has suffered more than is usually the case, which may be attributed to its constitutional habit of late growth, a feature of the variety; in mild climates, such as the south of France, it would probably continue to grow and bloom all the year round. I had a dozen or so of last year's novelties, all on the manetti. They were planted in December last, and of course were all budded the preceding summer; not one shows the slightest injury from the frost.

To utilize the considerations above laid down, I must perforce plagiarize from my esteemed friend our able Editor, to the effect that by early lifting, or semi-lifting, in mild autumns, we should check the growth and throw the plants into a state of rest. W. D. PRIOR, Clapton.

ORCHID GROWING—PHALANOPSIS SCHILLERIANA.

Through the kindness of Thomas Bewley, Esq., we were recently afforded an opportunity of seeing in flower a magnificent specimen of the glorious Phalanopsis Schilleriana. It is, we apprehend, not more than six years since this fine species—to our mind the most valuable of any of the lovely genus to which it belongs—first flowered in Europe in the famous collection of Consul Schiller at Hamburg, in honour of whom the specific name was given by his countryman, the distinguished orchidologist, Professor Reichenbach. Somewhere about the spring of 1862 it flowered for the first time in England in Mr. Warner's collection. A dozen or so was, we believe, about the greatest number of flowers borne at the time by either.

Rarely indeed is Mr. Bewley behind—nay, very often he is in advance of our neighbours in securing for his rare collection any novelty of merit. Almost simultaneously with the record of its first flowering with Mr. Warner in England, we had the pleasure of seeing a small specimen in flower at Rockville. The spike was only a few inches long, and the flowers not perhaps half-a-dozen. We were much impressed at the time with the beauty of the flowers, but the specimen afforded a weak idea indeed of the effect this magnificent orchid can produce when seen as we have seen it since, and more especially on the present occasion.

Notwithstanding the puny scapes and few flowers produced on the specimens in cultivation at that time, growers knew they had great things to expect when their plants should gain size and vigour, and their management be better understood; for they had heard of what collectors said of its beauty and glorious development in its native haunts, and were aware of at least one plant imported to England on which was a flower stem that had borne a hundred blossoms. Nor were these expectations falsified, and thanks to the skill of gardeners here and the other side of the Channel, so thoroughly has its cultivation been mastered that in first-class collections we now meet with specimens more than rivaling in luxuriance and beauty this or any met with in its home in the Philippine Islands.

The beautiful specimen now in flower at Rockville affords a remarkable instance of this. It would be more correct to say, perhaps, one of the beautiful specimens, for there are no less than nine in flower there just now; but one calls for especial notice. The beautiful blotched and marbled leaves are from fourteen to fifteen inches long, and between five and six broad. It has two flower-scapes, one of about four feet six inches in length, the other eighteen inches. The first of these midway divides into two branches, and these again divide into several ramuli, and carries no less than fifty of its charming flowers all fully expanded. Indeed, we believe it is a peculiarity of this species that all the flowers are open at the same time. The second and smaller scape was undivided, and bore fifteen flowers, nearly clothing its entire length with beauty—the total number of flowers thus numbering sixty-five! Altogether, it forms a charming object—just the one we would like to bring a friend whom we would wish to catch a little of the Orchidomania to see.

A second specimen, suspended near it, was little less imposing. It had only the one flower-stem, about three feet in length. It was not forked, as in the larger specimen, but at regular intervals it had four lateral branchlets, spread horizontally, and displaying its flowers, which were of a deeper colour than the former, to the greatest advantage. These splendid specimens reflected high credit on Mr. Sayers' successful management.

They are grown in very shallow galvanized wire baskets, suspended from the roof. The material Mr. Sayers grows them in is very fibrous peat and charcoal, surfaced with sphagnum. He has discontinued the use of sphagnum as the staple of his potting material for this and other orchids, for several valid reasons, which some day, perhaps, he will kindly put our readers in possession of.—Irish Farmers' Gazette.

CULTURE OF ANTIRRHINUMS.

The Antirrhinum, which has of late years been greatly improved by persevering florists, is now almost universally admired. A novel form of the *Antirrhinum majus*, called the "Tom Thumb Antirrhinum," recently introduced, will, I think, be a very great acquisition to our flower borders, as it grows only about six inches high. I have only seen one crimson-flowered variety worthy of the name, besides a pure white one, which I have reared myself, and which will be a good companion to the other. I hope, however, we shall soon get more shades of colour with a dwarf habit. Of late years it has been found difficult to keep the finer strains of antirrhinums from dying off very suddenly at times. Many growers, as well as myself, I doubt not, have experienced the same grievance. The plants, when beginning to fail, show symptoms of dissolution by their leaves drooping, and in a few days more they die, and I have sometimes experienced similar results with pansies.

I would not like to say decidedly what are the reasons of this sudden dying off, but I have frequently remarked and noticed that this plant, and many others which I could enumerate, when growing in a very poor soil, have their duration of life thus much more extended, although the same varieties fail under the unceasing care of the cultivator. There have been various reasons assigned for this, but I am convinced that very high feeding and cultivation has something to do with it. I once particularly watched the progress of an antirrhinum which had been self-sown in the lime seam of a south brick wall; it was a very nice crimson-scarlet, which flowered and stood the rigours of winter and the heat of summer for several years. I consider a great number of our flowers and other things are grown

by many with an ambition to have them look gigantic in habit and flower, without considering that such treatment is detrimental to their natural constitution, which should enable them to withstand vicissitudes or sudden transitions either of strong sunlight, heat, or cold; and the rich feeding practised by many is at the same time a great drawback to the maturation of the plant's functions, the rich feeding causing a greater flow of crude juices than the sun's rays can, through the foliage, elaborate perfectly.

Again, some, I am aware, will say that such and many other flowers have been overbred and cultivated. No doubt such treatment must naturally injure the constitutional properties, particularly as to duration of life.

The great mania for the one-shift system of growing pot plants will yet be in the remembrance of many; but it soon succumbed, for it was found that under such rich soil and rapid growth the plants were very short-lived. This I consider arose in a great degree from the too rapid growth and want of due time to mature the woody portion of the plants: a good proof to show that we may to a certain extent assist nature's laws, but if we overstep them, some such results will soon be visible.

The antirrhinum is worthy of more general cultivation than it has yet received. First, it is easily attained by seed; secondly, it will flourish in the poorest soil, and flower under many disadvantages; thirdly, it will produce flowers without intermission till the hard frost comes on. This past season the seedling antirrhinums in my borders were the admiration of many. No doubt the wet season greatly deteriorated the appearance of most other flowering plants, but the antirrhinums seemed to defy all inclemency of rain and want of sunshine better than any flowers I know. If the principal flower stems are cut off as soon as done flowering, the plants will continue to flower on, and when scarce a flower can be had to cut in the garden there will be plenty of blooms on the antirrhinums. Some will say it is not a pretty flower, but I consider a mixed collection of seedling antirrhinums will look very conspicuous, and remain longer gay than almost any other flowering plant. I must mention, however, that when the seed is not home-saved it should be bought warranted from a good collection, and that can easily be attained by giving a liberal price.

The antirrhinum is a very hardy plant when sown out of doors in any moderately light soil, say about the 20th or latter end of July, and if not too thick, the plants might remain where sown till spring; but if fine plants are desired, it is advantageous to prick them out into a rather poor than rich soil, and should any throw up flower-stems that season these should be pinched off.

The seedling antirrhinums flower more profusely than plants reared from cuttings, and their seeds may also be sown in the spring to flower late in the autumn. Their bloom will not, however, be so profuse as those sown the previous year; and the plants being young, and their woody portion not fully matured, they cannot be expected to withstand the rigours of winter so well. If it is desired to have them remain for some time in the same ground, dig in a good portion of old lime refuse and burned or charred earth.—WILLIAM MELVILLE, in "The Farmer."

THE BEAUTY OF THE GRASSES.

OUTLINE OF AN ADDRESS BY A VILLAGE PASTOR.

The grasses comprise all the plants which yield corn; most of those which constitute pasture, some of the best which yield sugar, and not a few of those which abound in useful secretions, grateful juices, and fragrant odours. Their thousands of species are distinguished from one another, not only by obvious hotanical characters, but also by their nutritive properties, their wonderful adaptations, their periods of flowering, their habits of hardiness and duration, their methods, and seasons of growth, and their love or dislike of particular soils and situations. Their flowers, though generally unheeded, or treated as something more than ordinarily mean by superficial observers, are remarkable for the perfection of their parts, the elegance of their structures, and the blending of only one set of differential marks with a great variety of generic and specific characters. When examined either by the texture of their organs, the number of their stamens, the relation of their sexes, or especially by their forms, appearances, number, and position, with the arrangement of their glumes, paleæ, and scales, they afford means of a far readier and surer discrimination than if they formed a part of the most gorgeous and complicated glories of the flower-garden.

The indigenous grasses which grow wild in Britain, are said to be about one hundred and twenty-five species, exclusive of varieties. These demand our most searching attention, on account of both their utility and beauty. They enter largely into the materials of that magnificent carpeting which forms the chief part of our grass lands, composing nearly all the natural herbage of our hills and valleys, our woodlands and open plains, and constitutes the principal portion of the sustenance of nearly all the flocks and herds of Britain. How interesting, too, it is to acquaint ourselves with that tribe of plants which give so much beauty to our island; which form so important a part in the gay and cheerful colouring in that permanently beautiful, though ever changing scenery, which makes the British islands the admiration of foreigners as they approach our shores. The olive groves of the sunny south, notwithstanding all the pleasing associations they conjure up, have yet a gray, sickly, melancholy hue; even in Valambrosa you can scarcely find a piece of green sward upon which to recline. The magnificent masses of foliage in a tropical clime, either entirely usurp the soil, or are broken into patches, leaving here and there stretches of arid sand, upon which the eye cannot rest with pleasure; while with us the surface, which is so generally open, presents a varied, yet uniform, object to the eye; which is kept in such a state of vivid green by frequent showers, as to make the British islands the first gems of the sea; their verdure contrasting so strikingly with the surrounding ocean, as to make them at times appear like emeralds set in silver. The sublime sentiments of the divinely inspired psalmist, will be appropriate to the pious soul looking upon these glorious works of our gracious Creator. "Thou visitest the earth, and waterest it; thou greatly enrichest it with the river of God, which is full of water; thou preparest them corn, when thou hast so provided for it; thou waterest the ridges thereof abundantly; thou settlest the furrows thereof, thou makest it soft with showers; thou bleesest the springing thereof; thou crownest the year with thy goodness, and thy paths drop fatness: they drop upon the pastures of the wilderness, and the little hills rejoice on every side. The pastures are clothed with flocks; the valleys are covered over with corn; they shout for joy; they also sing."

The grasses are not only beautiful and useful, and the study of them a delightful source of pleasure and amusement, but the Lord has made them both a means of instruction and of grace. They form, indeed, a very large part of the symbolic furniture of the Lord's larger temple; so that into

whatever part of it the thoughtless may ramble, either to waste precious time, or for more dishonourable and sinful purposes, there they are met by a teacher sent from God, and commissioned to admonish, reprove, and counsel them. To whatever part of it the pious may retire, either to meditate or to worship, there they are supplied with means whereby they can commune with God and the Saviour, and realize confidence, peace, and joy; so that the solitary tuft which rises in the wilderness, the oasis in the wide-spread desert, the extensive pasture lands of Britain, and the wider prairies of America, constitute a line of divine truth, sent through all the earth, and their words to the end of the world, saying, "All flesh is grass, and all the goodness thereof is as the flower of the field. The grass withereth, the flower fadeth, because the Spirit of the Lord bloweth upon it; surely the people is grass; the grass withereth, the flower fadeth; but the word of our God shall stand for ever." Should the rich man be tempted to trust in uncertain riches, and not in the living God; and having added field to field, till there was no place, that his mansion might stand alone in the midst of the earth; and believed that his house shall continue for ever, and his dwelling-place to all generations; the very grass upon which he treads will rise again to reprove him, and say, as when "the sun is risen with a burning heat, it withereth the grass, and the flower thereof fadeth, and the grace of the fashion of it perisheth, so also shall the rich man fade away in his days."

The poor disciple of the Lord is also taught, by this humble plant, a lesson of resignation to his plain, or, it may be, mean attire; for learning from the lips of wisdom that all outward adornings fall infinitely short of the beauty of grass, and that even "Solomon, in all his glory, was not arrayed like one of these," he becomes satisfied with his mean garb, and will seek rather than inward adorning, which is, in the estimation of God, of great value; and when he learns, from the same infallible teacher, that "if God so clothe the grass of the field, which to-day is, and to-morrow is cast into the oven," he will much more clothe those who may have only a little faith, he cheerfully submits to the will of God;

Is pleased with what his love provides,
And wean'd from all the world besides.

PEACH TREES INJURED BY WASHING.

A case has recently been brought under our notice which we regard as being of considerable interest to horticulturists. We therefore bring it thus prominently under the notice of our readers, with a view of eliciting the opinions of our scientific and practical friends on the subject. It is, as they are aware, almost a stereotyped practice in gardening, after pruning, to "dress" vines, peaches, &c., grown under glass with a solution or wash of some kind, with a view of destroying scale and other insects, or their ova. As is the case in medicine, the rationale of the practice is not always understood, still less the specific action of any particular ingredient, or the results of the combination of one or more of the many that go to add to the imposing appearance of the "prescription," but add nothing to its efficacy. All the good expected to be derived may, very probably, result from the specific action of one component; the addition of another may neutralize its effect, or their combination result in the production of a third agent that may be positively injurious. To proceed with our "case." In the garden of a most estimable resident nobleman in a western county there is a large peach-house which long continued, we believe, to afford excellent crops. The trees were pruned in November last, and "dressed" with a wash the formula for which was as follows:—

Sulphur	2 lb.
Lime	1½ lb.
Soft Soap	2 lb.
Common twist tobacco	½ lb.

the whole hoiled together for one hour in four gallons of water, and then strained. When cold, it was applied to the trees in the usual way.

Before proceeding further, it may be well here to remark that we are informed the trees lost their leaves early in September, and that when the wash was applied in November the wood "seemed hard and in good order." More than this, the gardener has been there for some time, and the wash, he says, in its components and their quantities is identical with that he used last and previous years, if not with advantage, at least with no ill effects. Not so on this occasion: the result of the application has been the destruction of the bearing wood, and, as a consequence, the loss of a crop for this year at least. In the absence of personal inspection, or of having seen any of the injured wood, we have no reason to doubt that the evil has been rightly attributed to the wash. The question then arises, Why did not the same result follow the previous and other years, the wash then used being in its composition and preparation in nowise different? The solution of this point that will most generally offer is that, notwithstanding what is stated to the contrary, the young wood was not thoroughly hard and ripe. Were the lights removed after the crop was off? Last season, we apprehend, was not specially favourable to the unaided ripening of the wood; or, again, that some deleterious ingredient may have inadvertently got mixed with the sulphur or other components. This last, of course, can only be ascertained by analysis; and we understand a portion of the wash has been placed in the hands of Dr. Cameron for the purpose. Now, we should be glad if any of our readers would do us and those immediately interested in this case the favour of their opinions and experience on the following points: First, as to the utility or otherwise of these complicated washes. In which of the ingredients is the efficacy supposed to be, or must it be the result of the combination of all? Are they supposed to act medicinally, or merely mechanically—that is, do they destroy insect life by their deleterious effects, or by merely forming a coating that destroys it, by shutting it out from the access of air? If any one or two of the ingredients have a specific action in the way first indicated, the others are superfluous. If the wash is intended to act in the second way, a wash very much more simple, and without deleterious ingredients, would effect the purpose, perhaps, better.

In the case of these peach trees it was suggested that after the injury they had received it would be better to discard them, and let young trees take their place. What do our practical friends say? Would they do this, or give them a further trial?—*Irish Farmer's Gazette.*

BEST 100, BEST 50, BEST 24, BEST 12, BEST 6. See GARDEN ORACLE for 1867 for Selections of Plants, Flowers, and Fruits, comprising the best in all the classes, an unerring guide for purchasers, cultivators, exhibitors, and all who are interested in practical horticulture.—[Advt.]

Literature.

The Miniature Fruit Garden. By THOMAS RIVERS. Longmans. 14th Edition.—This charmingly gossipy and seriously practical book needs no more than to be announced as having entered upon another stage of literary existence. Of course there are some additions: a restless, ever-inquiring, over-experimentalizing cultivator like Mr. Rivers could no doubt write a new chapter every week if he were to humour the *cacoethes scribendi*. Let it suffice for this notice to say that Mr. Rivers propounds a remedy or preventive of the bad habit of apricot trees in diabranching themselves, and the remedy consists in the adoption of single cordons. Now that the question of big *versus* little trees is being agitated, this book acquires new interest, and will doubtless be read again by many who have already perused it "hundreds of times."

Animal Sagacity. Edited by Mrs. S. C. HALL. S. W. Partridge.—This is a remarkably elegant book, ostensibly intended for young readers, but it will be strange if old readers do not dip into it and become fascinated with its contents, to the risk of depriving the youngsters of the boon intended for them. It contains about thirty stories of animals, all tending, by the display of their sagacity, affection, faithfulness, and even their humour, to promote in the minds of the young a taste for natural history studies and pursuits, and a kindly regard for animals. Mrs. S. C. Hall has displayed that good taste for which she is so well known and so deeply respected in the selection of the narrative and anecdotes; and some of the most eminent draughtsmen of the day have lent the aid of their pencils to illustrate them. Many of the pictures are worthy to rank high as works of art; as for example Mr. Harrison Weir's picture of Charlie the White Sergeant (a police-office dog); Danco, the linn; and the pair of horses at page 56. Dogs of course figure largely, and we will say bravely and brilliantly, in this book; and the hoy nr girl possessing it, and not prizing it, must be of a nature which it is impossible to please. We have been favoured with the loan of one of the cuts, as it happens to illustrate a subject proper to our pages; and as a fair sample of the contents, we give an extract on robins which will fit the picture:—

"ROBIN REDBREAST.

"Robin is always a favourite wherever he goes, and as in England, so in every other country he visits, he is called after some familiar name. In Denmark, he is known as Tommy Liden; in Norway, as Peter Ronsmad; and in Germany as Thomas Gierdet. Who can hear the words 'Robin Redbreast' spoken without recalling the old story of the pretty babes, deserted by their cruel uncle, who went wandering, hand in hand, up and down the wood, waiting for the man who never came back from the town, as he promised to do, and bring them bread?

Thus waudered these two pretty babes,
Till death did end their grief;
In one another's arms they died,
As babes wanting relief.

And thus they perished without one kind friend to drop a tear over them, and thus they lay exposed to the night dews and the winds,

Till Robin Redbreast piteously
Did cover them with leaves.

"Whether Robin ever did or did not shroud the bodies of the two babes in the wood with leaves, I will not pretend to assert, but I will say that Robin is a first-rate fellow, for he is not only kind to his wife and family, but he also displays strong attachments to mankind. Some say that because he flies into our houses, and perches up and down our rooms, that he is a bold, impudent bird. He certainly is very bold when either anake or hawk attempts to plunder his nest, but I think the reason he hops in at our doors and windows is that he trusts implicitly in our doing no harm to him.

"During this last summer a beautiful sight was witnessed by many persons in Peckham. In the fernery of Mrs. Cash, a pair of robins built their snug little nest. Whether the robins knew that Mrs. Cash and her daughters, being members of the Society of Friends, would be sure to treat them with kindness, I cannot tell. One thing is certain, the birds became so tame, that they would, even whilst seated on the nest, eat food handed to them by their admiring friends. By the kindness of Miss Newman, and the pencil of Mr. Weir, we are able to give our friends an engraving of the mother as seen when feeding her young ones.

"Perhaps more wonderful still is a story of a robin that quartered itself in the sitting-room of a shoemaker at Bishop's Cleeve. It took up its abode on the mantelpiece, and built its nest behind a tea-pot, on which, having laid its eggs, it used occasionally to sit, and was not the least put about by the presence of the family or strangers. It used to feed off the same dish with the shoemaker. Robins have taken up their abode even in stranger places than behind old tea-pots, and in watering-cans. They have built nests in saw-pits, on the beams of blacksmith's bellows, and in the rigging of ships, sailing with them when they went to sea.

"But the most astonishing thing I have to record of Master Bob is his affection for, and familiarity with, man. I have read of many persons who by whistling a call-note would gather robins around them, enticing them to perch on their shoulders, and feed from their hands. Mr. Burritt tells us that Mr. Fox, of Tregedna, near Falmouth, by persevering kindness, has so won the affections of the small birds, that they fly and hop about him when he calls; and Mr. Samuel Gurney, on visiting Mr. Fox, 'was perfectly astonished, on walking out into the garden, to see, on his sounding a whistle, the birds come fluttering round him. One robin was actually so tame, that it picked a piece of bread out of Mr. Fox's mouth.' I hope every one will read, who has not already done so, the verses which James Montgomery, 'the Christian poet,' wrote on a Robin Redbreast that came to his prison window every day when he was confined for truth's sake in York Castle, cheering the dreary hours by its presence and its song.

"I have said that Master Bob will defend his young brood against any enemy. One summer day, a hewer of granite, belonging to Dalbeattie, was plying his vocation at Craignaie quarry, when he was attracted to a certain spot by the cries of a bird in distress. Hurrying to the place, he saw that an adder, twenty inches long, was protruding its head over the edge of a robin's nest, built among the brushwood, and containing the poor bird's unfledged offspring. Bob was alternately coming down upon the spoiler, darting his beak into the adder's forehead, and then rising a yard or so into the air. The quarryman soon dispatched the enemy. Then Bob entered the nest, and having ascertained that his children were all safe, flew onto a neighbouring branch, and piped a song of triumph and gratitude.

"While this is being read, perhaps the snow lies deep upon the ground, and the flakes are drifting against the window panes; and suddenly a tap

comes to the window, and the book is laid down, and the children leave the bright, warm fireside, and looking forth, see poor Master Bob hopping shiveringly about. I am sure they will not begrudge him his crumbs, and from the depth of his grateful little heart he will sing his joyful song."

RATS AND MICE.

Those little animals are often most destructive pests upon our farms, and very little is either said or written about them. If more interest was excited, either by the pen, or otherwise, more care would be taken to keep these vermin under or rid the farm entirely of them. The rat-tribe is much more easily got rid of than the mouse colonies. Their habits are very peculiar. They occasionally come and go, no one knows how. I have experienced this upon my own farm. By care and perseverance they have been destroyed or banished altogether, and their runs and hurrows have been broken up and rendered desolate and unattractive. After the lapse of a few years, some two or three fresh comers have been noticed, and as these were only occasionally seen, they were not molested for a short time. Within a few months the premises have been overrun with them, and it has taken years to be wholly rid again. When once they succeed in gaining a footing under stacks, barn-floors, or permanent buildings, they are dislodged with great trouble and difficulty. The rat-catcher is the best remedy; poison is both dangerous and uncertain. To be constantly harassing and destroying them is the only sure way of a full riddance. Those not destroyed become disturbed and alarmed, and before long will take their departure to some more comfortable quarters. They should be constantly hunted by ferrets, their runs in the ground should be saturated with tar or lime-water, or be made otherwise uncomfortable; their runs about the buildings should be smeared with tar or other noxious ingredients. They are cleanly creatures and cannot abide such a persevering system of annoyance, and therefore quit their usurped homes. Everything should be done that good judgment dictates to make their return as miserable and uncomfortable as possible. My own barn has a deep coating of rubble, mixed with glass, around the foundation, which has for more than twenty years prevented any hurrowing there, and as soon as any of these audacious gentry make their appearance we take good care they shall not have much rest; believing this, that if left awhile in quiet they soon attract plenty of their fellows. With great care and persevering annoyance no farm need be pestered with rats. *Mice.*—These are such pretty little animals it seems a pity to destroy them so recklessly, but really they are so numerous and destructive that all pity for them has long died away, and few animals have fewer friends. Dogs, cats, poultry, birds, weasels, rats, &c., are all enemies to the poor little mouse, and far more destructive to them than the farmer's wife with her numerous traps. The increase of these little things is astonishing. If only a pair or two succeed in getting into a wheat stack built upon safety hovels, they will often do great injury by their extensive breeds and feeding; but in stacks built upon the ground, with free access, their numbers and destruction they make is often deplorable. I have seen stacks so thoroughly eaten through that the workmen at threshing day have sunk deep in amongst what should have been sheaves, but were all eaten to a kind of powder and chaff. They are far more injurious to corn stacks than rats, and no ferret hunting or ordinary means can be used to destroy them—hence the chief resort has been to poison. This mode of destroying mice has become a business; numbers of men travel the country with mice poison to dress stacks with it, or place it dexterously and subtly in poor mouse's way, so temptingly that his destruction is sure; strychnine, phosphorus, and arsenic being the chief ingredients. If the attack-dresser is clever at his business, it is marvellous what havoc his poison makes with the little creatures. Frequently upon threshing none are to be found alive, but vast numbers dead. Great care of the poultry is required for a short time after the stacks are dressed. Many mice either fall from the stacks dead or creep out to die. Poultry are very fond of them, and often eat them to their own destruction.—O. F., in "Agricultural Gazette."

Correspondence.

THE RECENT FROST—ROSES IN ESSEX.—In your issue for February 9th, you give a list of the minima temperature at various places during the recent frost, and as you invited in a previous number communications from your subscribers of their experiences of it, I am induced to offer you the results of my own, particularly as it shows that there was a great difference in the intensity of the cold at comparatively short distances. My residence is about sixteen miles east of London, on rather high land for this county (Essex), and whilst the thermometers at Chiswick have recorded 39° of frost, and at Slough 36°, we have here on the coldest night (that of the 4th of January) only reached 26°. This was taken from a Negretti and Zambra's glass, being five feet from the ground, on a wall at almost a due north aspect. I should think that the distance as the crow flies from here to Slough is little more than thirty miles, and to Chiswick say a little under twenty; and we have had 10° and 13° respectively less frost. I have a large bed of tea roses on their own roots in the open ground; I have been carefully over them, and I am gratified to find that I have not lost one plant. The sorts are principally Gloire de Dijon, Devoniensis, Madame Willermoz, Abrieot, Goubault, Madame Damaizin, Adam, Niphotos, and Madame Maurin. Many have had one-third of the wood from the top destroyed, but all are now shooting vigorously from the lower eyes; in fact, they are pushing much faster than I like to see them just yet, as it is a long time till spring. I must, however, say that these tea roses are certainly in a very sheltered garden, protected by high walls and a laurel hedge on the north, east, and west sides, and that the bed was covered four inches deep with cocoa fibre and stable dung early in the winter. On the wall facing the west of this garden I had a plant of *Solfaterre*, which flowered unusually late, and had multitudes of leaves on when the frost came; this plant I fear is dead, and I believe I may say is the only one I have lost through the frost. Of the perpetuals—which Mr. Taylor, in your issue for February 9, classes as "tender"—I have thirty-two varieties out of the seventy-eight he enumerates. These thirty-two, together with many of the kinds he mentions in the other two classes (in all a little under 200 plants) are growing in another garden a little way from the house, and in this they are in a position of fair average exposure, in no way unusually sheltered except from the east, and I believe I may safely say that there is not one of them, not only not killed, but not even seriously injured by the frost. In the winter of 1860 I lost a great many perpetuals by the frost, particularly the light-coloured varieties. I had then a great many plants, both

standards and dwarf standards, of Duchess of Orleans, and I lost every one; and I think that if there is one of the sorts I have which shows more signs of injury than another during the recent frost it is this one; perhaps the next to it is *Mdlle. Bonnaire*. I must confess to some loss of bedding plants, but when I tell you that they were in a cold pit you will probably say that I could have expected nothing else. I had a cold pit filled with geraniums, fuchsias, calceolarias, verbenas, and petunias, and when the frost came all I could do was to mat them down securely five inches thick, and protect the outside walls of the pit with long manure laid thick all round it. I can assure you I did not expect when the frost kept on day after day that I should save one of them, and I durst not open the mats to look at them whilst the frost lasted. Unfortunately, they were not as dry as they ought to have been when the frost came, or I believe I should have had but very little loss; but the lights had been all tilted off one fine morning just before the frost, to give plenty of air, and my man had gone away to collect some leaf-soil, and a sudden shower came on and drenched them thoroughly. As it is, however, I have saved about one-third of the geraniums, half of the fuchsias, all the verbenas and calceolarias, but the petunias are all gone. In the greenhouse I have not suffered at all, thanks to using mats to protect all the glass portions of it. The fire was left on the night previously referred to till about midnight, and would probably burn from two to three hours—not more. At the time of leaving, the thermometer inside stood at 47°, and in the morning at eight o'clock when I went in, I found that the lowest point it had reached was 34°, or two degrees above freezing-point. I would recommend your readers who have small greenhouses to be always provided with mats sufficient to cover the glass-work; they keep out a great deal of frost, and save much firing, which is very much better for the plants in mid-winter; and then the trouble of putting them on and taking off is really not great. A few brass hooks, small but strong, serve to hang them on the upright portions. The hooks are not unsightly, and the top can easily be covered with care, by using a small ladder. In conclusion, if I were asked to what I attributed my immunity from injury in case of my roses, I should say to *thorough drainage* (as even 26° of frost is trying to the teas and noisettes). I think this is a most important point. The protection I have before referred to for beds of tender roses on their own roots will also be found of immense service; the cocoa-fibre should be put round the stems to keep them from damp, and the stable dung (moderately decayed), spread equally over the bed.

AURICUS.

THE JUDGES AT THE INTERNATIONAL EXHIBITION OF 1866.—I see by your report of the discussion which took place the other day at the Royal Horticultural Society's annual meeting, that the committee of the International have a large surplus in hand which they do not know what to do with. Will you permit me to ask the managers of the late show, through your columns, the reason why the judges are not to be paid? I allude more particularly to those who came a long distance. I know many who came from Scotland and Ireland who could ill afford to pay all their expenses. It appears to me that it would only be just and right to make these gentlemen some allowance out of the surplus funds. In the letters sent to the judges it was stated that owing to the affair being somewhat of a speculative character, the committee could not arrange to pay for judges. But seeing that it has proved a monetary success, I think this a subject that ought to engage the attention of the committee. I don't suppose they will take any notice of this suggestion, but I know the feeling among the judges is very marked on this point, many of whom look upon the matter I have alluded to as a shabby piece of business.

A JUDGE AND SUBSCRIBER.

ATMOSPHERIC MOISTURE IN VINERIES.—Will you give me your opinion about moisture to vines at night. Should the floors of vinerias be kept moist at night—that is, when the vines are in leaf? Some of our best writers say "yes," while I know for a certainty that it is condemned by some of our best growers—Mr. Hill, of Keele Hall, for instance, who always gives air for half an hour after the afternoon syringing, to dry up every particle of water off the floors. But then it must be borne in mind that his borders are inside, and of course when the vines are in progress they are moist from watering, &c. My opinion is that it is in accordance with nature to keep them moist at night, by filling the troughs and throwing water on the paths, and allow them to get dry some part of the day. Please say if I am right or not.

W. D., *Edgbaston, Birmingham.*

[We are thoroughly of opinion that many practitioners overdose their vines with water both above and below ground, and that many ailments of vines are produced by excess of atmospheric moisture at night. No one has yet determined the precise degree of saturation of the atmosphere that is best for vines, but every experienced cultivator knows that if the atmosphere of a vinery is kept in so damp a state as would just suit for a cucumber frame, the vines can do no good in it. A dry atmosphere is not good for the vine, but on the other hand an excessive use of the syringe and the creation of a steaming atmosphere are far more injurious than extreme dryness. What do our grape-growing readers say to this question?—ED.]

Replies to Queries.

Centaurea candidissima.—S. W. B.—This generally puts up a number of suckers and small shoots from the bottom of the plant, which readily strike in sand under a bell glass; if your plant is not furnished with these, encourage it to make side-shoots by nipping the top out, and set in as warm a place as you can, and you will soon have a crop of cuttings that will make nice plants by bedding-out time. Plants from seed come true with very slight variation, but the normal type will be more uniformly preserved by means of cuttings.

Quinces.—H. Saunders.—You might try thorn and medlar stocks raised from seed; but we must confess that we have no experience in the working of the quince except as a stock, having always grown it on its own roots. This correspondent esteems the quince highly, but it does not thrive on its own roots in the part of Westmoreland from which he writes. He finds it do best on *Cydonia Japonica*. Can any of our readers suggest a suitable stock besides the *Cydonia* and the pear? We should be strongly inclined to give preference to the hawthorn for an experiment.

Cinerarias from Seed.—M. E. R.—Fill a seed-pan with a mixture consisting of equal parts fine loam from rotted turves, leaf-mould, and hotbed manure rotted to powder. The mixture need not be sifted, but must be well broken up, so that there are no lumps in it, and some of the finest portion must be spread on the top. Press it lightly to make an even surface, sprinkle the seed very thin, and cover it with a mere dusting of any fine earth. Lay a square of glass over the pan, and place it in a warm still corner of the greenhouse. As soon as the plants begin to peep through, take the glass off, and when they are large enough to handle pot them off separately. Any

light clean soil will serve for sowing *cineraria* seed, and it is best not to place it in a strong heat.

Peas.—R. B.—There is no better way than to open trenches two feet deep; put a good layer of manure at the bottom, and then fill up and sow. If peas were always treated this way, we should never hear of mildew as soon as hot dry weather sets in.

Bees.—R. W. P.—We have heard that Messrs. W. Cuthush and Son, of Highgate Nurseries, have made arrangements to supply swarms at 30s. each; this charge to include hive, hloek, and super. This is a very wise proceeding on the part of Messrs. Cuthush, and we wish them success in the undertaking, for the want intended to be supplied has been long felt. In fact there are thousands of persons who would keep bees if they did but know how to obtain swarms to begin with.

Purchase of Seeds, &c.—"Constant Subscriber" must be a very inconstant reader, not to know by this time that we never recommend traders for such things as *Primula*, *Calceolaria*, and *Cineraria* seed. Apply to any of the seedsmen who advertise in this work.

Names of Plants.—Amateur.—The white flower is *Spiraea prunifolia*; the silvery-leaved plant is not a *Centaurea*, but *Cineraria maritima*; the fern is the common Polypody, *Polypodium vulgare*. We cannot advise you on the subject of emigrating, not knowing enough of your objects, circumstances, &c.; but we would suggest that it would be well for you to make enquiries respecting Queensland.—T. B.—No. 1 is *Spiraea prunifolia*; No. 2, *Deutzia gracilis*; No. 3, not in flower, but looks like *Sedum denticulatum*.

Everlastings and Grasses.—G. Smith.—The following, six of each, will be found of great service for winter bouquets, and are, moreover, most beautiful plants for the garden. Everlastings: *Acroclonium roseum*, *Helichrysum bracteatum*, *Helichrysum compositum*, *Ammobium alatum*, *Rhodanthe maculata*, *Waitia acuminata*. Grasses: *Stipa pennata*, *Bryza maxima*, *Agrostis pulchella*, *Agrostis nebulosa*, *Milium multiflorum*, *Eragrostis elegans*. You may perhaps succeed in striking cuttings of *Lobelia*s now on a top shelf with a bell-glass over them, but it will be slow work at the best without heat in some way, and you must not expect an early bloom. It would be almost better to sow a pinch of seed, and cover the pan with a square of glass, and put the pan on the top shelf. If a pan of seeds and a pan of cuttings were both started on the same day at this time of year, without the aid of artificial heat, we should expect the seedling plants to quite outstrip the cuttings before June; certainly self-sown seedlings, which abound in every garden, flower freely by the beginning of July.

Furnishing a Flower Stand.—Brum.—You cannot do better for furnishing the lower part of the stand, where there is a defect of light, than provide a few of the most robust hardy or nearly hardy ferns. You do not say what conveniences you have for growing plants, and therefore we can only suggest common *Hartstongue*, common *Lastrea*, and *Polystichum aculeatum*. Many greenhouse ferns would also suit well if you can help them through the winter, such as *Asplenium huliferum*, and *Pteris flabellata*.

HOW TO FORECAST THE WEATHER.—The following were among the maxims of the Meteorological Department in determining their forecasts. They are selected and rearranged from the digest made by the committee and appended to their report. It is to be hoped that meteorologists will both amend and add to this imperfect list, on which the committee remark: "Some of these maxims rank among the long-established truths of meteorological science, while others are clearly open to considerable doubt." 1. Atmospheric or air currents. In the latitude of the British Isles, and of north-western Europe generally, there are two, and only two essentially different atmospheric currents—one S.W., running from the equator towards the pole, and the other N.E.; running from the pole to the equator. The characteristics of the S.W. current lie not only in its general direction, but in its quality; for it is light, warm, and moist. In other words, its presence is shown by a low barometer, by a high thermometer, and by a small difference between the wet and dry bulb thermometers. The characteristics of the N.E. current, in a similar way, lie not only in its general direction, but also in its quality, for it is heavy, cold, and dry. In other words, its presence is shown by a high barometer, by a low thermometer, and by a large difference between the wet and dry bulb thermometers. The weather in this country depends almost wholly on the conflict, combination, alternate preponderance, or alternate succession, of portions of these opposite currents. Not only is the actual presence of either current shown by its corresponding instrumental tests, but an approaching change from one current to the other is foretold by the instruments beginning to change their indications. (Hence, as changes of weather must necessarily commence at some places earlier than at others, there is great advantage in receiving by telegraph information of the state of the weather, and of the instruments at many stations.) When S.W. and N.E. currents alternately prevail, the wind blowing over any station has a strong tendency to "veer," and not to "back." That is to say, the general order of the changes is N.E.S.W.N., and not N.W.S.E.N. 2. Weather changes. Gradual changes of the weather are shown by a gradual rise or fall of the barometer; for instance, at the rate of one hundredth of an inch in an hour. Great differences of temperature at the same, or adjacent places, are followed by changes of weather. Rapid changes of all kinds commonly presage violent atmospheric commotion. The result of all rapid changes in the weather, or in any of the instrumental indications, is brief in duration; whilst that of a gradual change is more durable. 3. Direction and force of wind. The wind usually blows from a region where the barometer is high to one where the barometer is low. The force of the wind is usually proportionate to the differences of barometric pressure at adjacent places. In other words, the greater the barometric tension the stronger the wind. Strong winds are far more steady in duration than light or moderate winds. 4. Gales or storms. Great storms are frequently preceded by excessive meteorological disturbance, as by heavy falls of rain or snow, by much lightning, by unusual cold, or excessive heat. Sea disturbance often precedes gales. Great storms are usually shown by a fall of the barometer exceeding one inch in twenty-four hours, or by a fall of nearly one-tenth of an inch in an hour. The barometer frequently continues high during a N.E. storm, but there is a fall of the thermometer. Most of our violent storms travel bodily in a N.E. direction. 5. Calms. Calms may be due to either of three different states of weather—1, the appulse of winds coming together from opposite quarters; 2, the divergence of winds going towards opposite quarters; 3, the centre of cyclonic storms. The barometer rises in 1, and sinks in 2. It is extremely low in 3. When the S.W. and N.E. currents intermingle, water is precipitated in the form of cloud, rain, or snow.

The Gardener's Magazine.

SATURDAY, MARCH 9, 1867.

HORTICULTURE WILL HAVE A FULLER ILLUSTRATION AT THE FRENCH EXHIBITION than it has ever received in connection with any great international gathering. The building itself, enormous and highly convenient as it is, if not striking or beautiful externally, would have afforded interest enough to attract "all the world" to *la ville de Paris*; but the French, with a taste very much superior to our own, have surrounded the building with a beautiful garden and park, dotted with minor buildings representing the dwelling-houses or some characteristic buildings of every country, and tastefully planted in almost every part. The whole of the vast space surrounding the building will be a garden to some extent, while a large portion of the grounds will be so in quite a special degree. In the centre of the building there will be a geometrical garden; all the rest will be laid out in the English or natural style, at which the French have of late years become no mean proficient. The ground will be very extensively planted in all directions with choice shrubs, brought at great expense from many parts of the country; and when the summer arrives an immense number of those fine sub-tropical plants in the culture of which the Parisian gardeners are so famous will be planted, so that every visitor to the Exhibition will have the advantage of seeing this phase of gardening fully represented. Everywhere the grass has room to spread itself out; it will be kept as green as a British meadow on May-day, and in the keeping of grass, even in the heart of Paris, nothing seen elsewhere can approach the result attained by the French gardeners. Thus the visitor to the Exhibition can step from the crowds and bustle, and, we may add, weariness, of the great mart to the cooling and refreshing influences of a delightful garden.

This garden, while beautiful as a whole, and which, even in a half prepared state, has left a good impression upon all visitors, will have an especial interest for horticulturists. It will be to a large extent an outdoor exhibition of gardening, a phase of exhibition work which, while it cannot present to us beauty and perfect flush of health, as we see in our one-day displays, will yet be highly interesting to all real horticulturists. In it, among many other objects of interest, will be arrayed specimens of the various modes of fruit-tree culture pursued in France; and many of our readers know how highly the French excel not only in the beautiful training of a tree, but also as fruit producers. Some of the handsomest specimens of both young and old trees have been transferred bodily to the grounds of the Exhibition, and there trained against the surrounding wall of the park; while the small standard and other forms, which some people in England take credit for "originating," but which have been seen for generations in humble French gardens, are represented in full. Thus, with a full display of "sub-tropical gardening" and fruit-tree culture, there can hardly be any lack of interest, especially when it is remembered that M. Barillet, the chief of the gardens of *la ville de Paris*, is the manager also of all the gardening round the Exhibition. But there will be many other objects of interest in the open air in this way—shrubs, trees, and in fact most branches of outdoor gardening will be represented; so that if no one grand and beautiful effect, like that seen at South Kensington last May, be produced, the exhibition will quite make up for the want by the great variety of interest displayed. But what it will prove as regards immediate floral display can only be learnt during April and May. There is a large number of beautiful curvilinear conservatories being finished in the grounds, which will not only serve as receptacles for the tender-plant collections, from tall palms to orchids, but also to illustrate the most advanced and approved modes of heating, ventilating, and constructing hothouses. In fact, in this way alone the exhibition will prove unique, and in nearly all the houses there are peculiarities of structure and fitting which are new, if not instructive, to the British horticulturist. There are to be ponds for aquatic plants, and winding rivulets and wide-spreading pieces of water near the cascades, or rather near the elevation for the enormous marine and fresh-water aquaria. These are so arranged that they can be viewed on all sides by the visitor, *i. e.*, he can go below into a large and tortuous stalactite cavern, and there looking up see the "water snakes," "and as they rear, the elfish light fall No. 97, NEW SERIES.—VOL. X.

off in hoary flakes." Perhaps, for there is no fish in either yet; but when there is, the curious in such can satisfy themselves thoroughly by walking round an elevated walk, and looking in on the fish; by descending where wide side openings reveal all their movements in that way; and by descending deeper into the stalactite cavern the inhabitants of the deep are seen gliding overhead; while the smaller inhabitants of the deep, and the very useful inhabitants of the river, will also be fully and ingeniously represented, as will the loved *huitre*. All these objects of interest are placed in the centre of the special horticultural department, and when completed they will certainly lend it much interest.

But we must not anticipate. Doubtless numbers of our readers will see the Exhibition, and in any case it will suffice to describe it when completed and opened; but it is not too soon to ask ourselves, Have we anything to learn from this display? Even our intelligent British gardener too frequently thinks

"There aint no light in natur' when he winks;"

and we may venture to predict that much of this insular vanity—and we might say insular ignorance—will vanish after a visit to the French Exhibition, and that even a glance at the way the public gardens, avenues, parks, &c., are kept and planted in summer would remove a great deal of it. It is quite a common thing to hear English gardeners disparaging their French contemporaries; but we would ask such, Are you not deeply indebted to them? Did not sub-tropical gardening, which is likely to have such a good influence on British horticulture, by forcing the importance of verdure and grace on flower-gardeners, if in no other way, originate with French gardeners? Undoubtedly it did, and it is carried on to such an immense extent there, that such plants as the finest kinds of *Cannas*, *Aralia papyrifera*, with hundreds and hundreds of species of fine-leaved plants, are planted out by the thousand, and propagated and preserved at less cost than the bedding plants in a British garden, as may be seen in the magnificent propagating establishment or nursery, where all those sub-tropical plants are raised and preserved over winter, in the Avenue d'Eylau at Passy. This establishment we should particularly advise any readers who go over to have a peep at, as from it nearly three million plants are annually supplied to the various gardens, squares, avenues, &c. about Paris, at a cost of less than a farthing a-piece; and among the "bedding plants" are included in the calculation many species of the rarest exotics and finest palms. And observe; all the gardens that belong to the state—such as those of the Luxembourg, the Jardin des Plantes, the Tuileries, and others—are not supplied from this establishment, but propagate and furnish their own stock. And the spring gardening bedding system, so extensively developed at Cliveden and other places of late years, doubtless many of our readers think of British origination; but not so; like most of our plays, it is merely adapted from the French, its chief practitioner in this country having first seen it in Parisian gardens. And so of the dwarf fruit-tree system, upon which Englishmen have written as if they had invented it, and which most gardeners think a new thing, whereas it has, as we have before remarked, been practised for generations in humble French gardens. It is true they do not grow such perfect specimens of azaleas and geraniums as are seen at our shows, although there is very good plant-growing in France; but then, on the other hand, they are far before us in tasteful disposition and arrangement of summer plants. They make a great stride towards true interest in gardens by having different arrangements and combinations, and even, if possible, different plants, in every square, &c. The way they introduce healthy perfect trees, and an abundance of them, into the heart of Paris, and plant them along every new street and boulevard, is most creditable; every young tree having a wide circular grating at its base to prevent the soil from being hardened, and to allow of water being given when required; so that in a few years' time Paris will be more beautified by vegetation than any city in Europe.

The Billancourt section of the Exhibition, or in other words the island of Billancourt on the Seine, where the various operations of agriculture, and the various modes of cropping will be exhibited, will of course be of interest to horticulturists, and should be seen by all such who have the opportunity. This island can be reached in twenty-five minutes from the Exhibition, by road or rail, or by the river steamers. It comprises about fifty acres of medium soil, which area will be divided into several districts, and in these will be arranged specimens of many modes of husbandry and cropping.

One division will be devoted to the best descriptions of agricultural machinery, and arranged under sheds, with models especially of improved agricultural buildings of all kinds; and not only agricultural buildings, but others, such as poultry-houses, and other matters that are usually associated with the farmyard and the country-house. The various modes of manufacturing substances derived from roots, the produce of the farm (such as sugar and starch), will also be illustrated, while whisky, &c., will not be omitted, in case a highly polished and civilized community should forget the art of making it; dairy produce, bee-feeding and rearing, and improved beehives; seed-crushing, wine-making, &c.—these will be all represented. Here also will be shown many of the smaller operations in connection with husbandry, such as wheelwrighting, coopering, the blacksmith's shop, the charcoal burner; brick, drain, and tile making, &c.; the preparation of bones, crushing of coprolites, manufacture of manures, preparation of artificial manures, and the disinfection of animal matters intended for manure. Another district will be devoted to machinery at work in the culture of the soil—ploughs, harrows, &c., *ad lib.*; while the farming operations of each month are intended to be represented as closely as possible on a small scale. Another district will exhibit the different kinds of pasture, with samples of the best varieties of native and exotic grasses; water meadows, irrigation, liquid manuring, draining; while full provision is made for the trial of machinery, from hay-making to clod-crushing. Lastly, a division will be apportioned to the culture of root crops, from beets to potatoes—to the exhibition of market-garden produce, fruit, flower, and kitchen gardens, nursery grounds and shrubberies; strawberry beds, roseries, cress beds, &c. A most interesting island indeed, if all that is proposed be carried out. With such attractions, let us hope that prices will not be so high in Paris as to exclude all but the wealthy; for, however desirable it may be to see those things, we would rather advise our readers to stay at home than to go, if prices reach the exorbitant rates it is supposed they will in Paris during the great season of 1867. And to those who cannot go if such be the case, and also to those to whom it is not very necessary to see this great meeting for professional or other purposes, we say wait for another year, and then you can see Paris, and anything that is done in it, without being crowded and jammed in every public building you desire to see, and get everything you want at a reasonable rate.

MR. HULLETT HAS CREATED A SENSATION by his offer of seeds of the Sugar-cane Grass, which he described as "perfectly hardy, and bearing from six to eight times the quantity [of grain] per acre that wheat does; but the bread made from it is more nourishing," and "the leaves and shoots are invaluable as food for cattle." Some of the recipients of the seeds are anxious to see in their "mind's eye" the plant about which such startling tales are told. Now we confess we do not know it, for there is no such species in the books or herbaria as *Sorghum tartaricum*, which is the name under which the seeds are offered. But, if guessing may be allowed to those who profess to know something about plants, we should guess the plant to be *Sorghum saccharatum*, which was introduced to cultivation as a fodder plant about ten years since, and which proved a failure, and is now scarcely known except as an ornamental grass, which is occasionally grown in gardens, and is considerably less ornamental than the common maize. That it is not new is proved by the fact that it was described and figured in the *Floral World* in 1858; that it is not likely to be of much use may be conjectured from the fact that the species of *Sorghum* have never been known to ripen seed in England.

Mr. Hullett may of course be in possession of a cereal that no one else has seen or heard of. Should this prove to be the case, we shall, at the first opportunity that occurs for becoming acquainted with the facts, invite our readers to pay to that gentleman all the honour that is his due, especially if before uttering any laudation we can but taste a loaf of bread made from English grown grain of *Sorghum tartaricum*. There are several other interesting subjects that Mr. Hullett professes to be in possession of that we are anxious to know more about. He has, by private letters, offered to some of our friends plants that must be truly wonderful, if they at all bear out the descriptions he furnishes of them. One, for example, a passion-flower, produces fruits superior to pine-apples. Another produces fruits of so gigantic a size that within them are found many seeds "as big as a child's head;" and, to avoid making a catalogue of the Hullettian museum, there is another passion flower the fruits of which are black, delicious, and when boiled taste like green peas! We have not met with any one who has seen these wonders; we have not been able to discover in any works of authority figures or descriptions of them, and we therefore draw upon our imaginations respecting their wonderful qualities, and wait for the day when they shall be fully revealed. Some of our friends have done more; they have drawn upon their bankers, and purchased these plants at one and two guineas each; so, if we have a little patience, we may see the fruits of them, or we may not, for everything in the future is uncertain.

We can call to mind that some time since Mr. Hullett was contributing papers on tropical fruits to a contemporary. He then generously offered publicly to give to microscopists samples of the pollen of *Monstera deliciosa*; and those who accepted the pollen were favoured with private offers of these passion-flowers and big-as-a-child's-head-seed-producing-fruits. In making the offer of the Chinese grass, Mr. Hullett underrated the demands that would result, and there has been a great outcry from correspondents who had to wait for seeds. But Mr. Hullett appears to have satisfied all claimants at last; and, amongst the many persons who have defended him, one testifies to having received the pollen of *Monstera deliciosa*,—a proof that Mr. Hullett really did possess the plant, and was generous in respect of the pollen. The name of this gentleman is Walker.

OZONE IS A MYSTERY; the best that at present is known of it is that it is a form of oxygen; a sort of oxydized oxygen, and possessed of potent powers in the reduction of putrefactive substances, and in promoting the vigour of animal life. The principal defect of the atmosphere of a great town as compared with the country is deficiency of ozone. Where this mysterious gas abounds, and quickly stains the test-papers used to detect its presence, human life is not only possible but agreeable; for ozone makes the cheek ruddy, the appetite brisk, and nerve and muscle alike healthy in tone and tension. Professor Daubeny contributes a trifle of some importance to our at present scanty knowledge of ozone. He has conducted a series of experiments, the result of which is the discovery that as plants decompose the carbonic acid of the atmosphere, and appropriate the carbon in building up their tissues, they set free ozone. This operation takes place in connection with the action of actinic light on chlorophyll, and is therefore the normal result of the normal effect of sunlight upon plants. Here, then, is a new argument in favour of beautifying all our towns and cities with trees and other forms of vegetation suited to the few open spaces that exist in urban districts; and it is rendered additionally probable that the reduction of the average term of human life in towns, as compared with the average term of the country, is to be attributed to the absence of vegetation, which not only liberates oxygen, the life-giver, but ozone, the poison destroyer.

WONDERS WILL NEVER CEASE.—A contemporary informs us that M. Bossin is quite convinced that there is a great advantage in planting early potatoes as contrasted with late ones. Many besides M. Bossin are equally convinced, and have been convinced a considerable time. For example, in the "Garden Oracle" since 1859 the public have been annually assured that potatoes ripening off before August are rarely or never touched by disease; that the disease does not occur until heavy rains, accompanied with a low temperature, occur; and that the difference between early and late potatoes in a year of disease will sometimes be a whole crop of fine tubers as compared with a field of rottenness. We congratulate M. Bossin on his conversion. Better late than never.

BROCCOLI CULTURE.

The esteem in which the broccoli is held does not seem to ensure it so extensive a cultivation as might be expected. In market gardens and gentlemen's places it is well done, and grown in quantity, but a great many amateurs who have small gardens, and a great many gardeners in single-handed places, fight shy of broccoli, as if it wanted some sort of magic, which it don't, for it is easy enough to grow plenty to make a better dish for the table than any other of the ordinary greens that are in use in autumn and winter. As far back as I can remember—and my knowledge goes a long way now—we used to grow broccoli as well as in the present day, and I am half inclined to believe we had as good sorts, though I hear from London now and then of great things in that way. I suppose fashion governs the seed trade as much as it governs our shoes and stockings and hair-cutting; and we don't always know when we are under the spell of fashion, but think we are governed by necessity. I remember when I first thought about getting on in the gardening way—if I only go back as far as 1811—that we used to fasten our shoes and breeches with great buckles that were no use at all, yet they appeared to be quite necessary. It was the height of the fashion then to appear in a tight fit, and terrible high top-boots; and if a real dandy had let all the false teeth fall out of his mouth, he could not have stooped to pick them up again, without —; but no matter. I remember, too, the extreme gentility of pantaloons and spatter-dashes, which were a sort of short ankle leggings. There were no trousers, or Wellington or Blucher boots then, and perhaps you will say there was no comfort, and really I think you will speak the truth in that. The most amusing of my past remembrances of this sort is that which occurs when I see nicely-dressed boys and girls of the present day, who, whatever harm fashion may be doing to them, are at least so clothed that they have the use of their limbs; and I see a far better race growing up than fashion allowed in my early days. Then "the breeching" (as it was called) of a growing lad was an awful business. He was thrust into top-boots and tights with kneec buckles and buttons, and a cloak over all that made him look like Don Juan; and I am sure he was in great part encouraged to play the part of that objectionable character by the example set him, and even by the clothes he wore. I remember these things with perhaps the greater force because the growing of broccoli for Covent Garden Market was one of the earliest bits of practice I had; and the London fashions, both in dress and in vegetables, burst upon my simple mind simultaneously. I learnt at the same time how kind and free and accommodating is nature, for we used to work up for market even to a day; and also how harsh, and tyrannous, and crushing is fashion. Yes, I soon learnt that to grow a plant we must humour its constitution; but to clothe man, that was not necessary; indeed it seemed quite a necessary thing to destroy the constitution, and make him a cripple if possible. When I came to London, the doings at the market gardens were the chief objects of my curiosity. I had been saving a little money (and it was but little indeed) to enable me to have something in my pocket on first entering the wonderful town. About 2 a.m. on a severe frosty morning in February, I picked up my traps and started. By Jove, how it did blow and snow before midday! But on I went, full of heart and hope, ready to weather any storm, and with my mind bent

on market gardening. Crossing Wimbledon Common was like being the sole actor in an incantation scene. It was wild, and bleak, and dangerous; and there stood an old gibbet and chains and irons clanking in the howling wind. Glad was I when I reached Chelsea Common (it would puzzle you to find it now), which was a trifle less dreary; and at last finished my day by getting a job at a recently made market garden. Here then I was in luck at last, and I began to study the system which was then thought to be perfection, not knowing at all how much I had to learn, and how I should have to go on learning to the very end of my days. I began at ten shillings a week, and left off at thirty shillings, which was a large sum then for garden wages, and I went through the whole of the work from that of labourer till I became entire manager. At that time there were market gardens, nurseries, and florists' gardens right and left all the way from Pimlico to Putney Bridge; I got acquainted with most of them, and with Covent Garden too, where I saw better things than I had been used to even in good private places in the country, as is the case at the present day. My master died after I had served him five years, and I found a berth in a larger garden, and I began to look out very sharp for new ideas, and for all the nice points in market practice. Early in life I learnt that the wise man is his own schoolmaster, and this motto I leave to the thousands of young gardeners who read the magazine: if they want to learn and rise, they must be always at school, whether in the potting shed, or on the potato ground, or banking up the furnace fires, and be their own schoolmasters all the while. After twelve years of hard work, and for a good part of the time having the entire management of extensive market gardens where forcing and every other department of market practice was carried on in a most spirited manner, I began to think I had had enough of it, and longed to make a change. In due time I succeeded in this, and I have not been at much loss to know how to grow good fruits, vegetables, and salads all my life since; and this remark brings me back to the broccoli, from which I have strayed a bit, and hope my rambling reminiscences may not be dull, as at my time of life, and after so much activity in horticulture, I count upon a sort of privilege to gossip a bit, especially if I can say a word that may be useful to the young men.

The sorts of broccoli in use in my early days were an *Early White*, a *Late White*; an *Early Purple*, a *Late Purple*; a large growing *Brimstone* variety, and a good *Purple Sprouting*, as nearly as possible the same sort as is grown now; indeed I can see no difference between a good sample of *Purple Sprouting* of the present day and that which was grown in 1811, so the new varieties of this class of the past fifty years are not of much consequence, except to the vendors of them who get a larger price by selling an old variety under a new name. I used to see the sorts named above in all the market gardens about London. They were grown on deeply trenched and well-manured land. There was a large market gardener of those days who kept a fruit shop in Covent Garden, and another in Piccadilly—a man who was master of everything he touched, whether fruits, vegetables, or salads. His name was Grange, and in every seed catalogue of the present day you find *Grange's Broccoli*, a capital early white sort, which he used to grow well, and which he bred from the common market white, and improved by rendering it handsomer and earlier. I say you see this in the catalogues now, but I believe it run out years ago, and was actually lost, but strains more or less like it bear the name, and some of them perhaps are as good as the original. It is an argument in favour of the new sorts that the old ones tend to degenerate, so that the races require now and then a new spurt to give distinctness of character and keep up high quality. The best successor to Grange's *Early White*, of late years, is Snow's *Early White*, which for many years was a most useful autumn and winter broccoli. This, like Grange's, has degenerated, and after taking every pains to get it true, I have had it come all sorts of shapes, sizes, and colours—frothy, dirty, and cankered, so that I have given it up altogether. The *Malta White* is still a good one for early spring; the true sort presses its leaves close in upon the flower, protecting it completely. This, however, sometimes disappoints, owing to spurious seed being sent out under its name. *Osborn's Dwarf* is a neat little delicate thing with me, but throwing its heart so much open that if not looked after pretty sharp, every slight morning frost discolours and disfigures it. Of all the really useful white varieties I am acquainted with, the *Cornish* is, when true, the masterpiece both in quality of flower and in accommodating habit of growth, for by making three little sowings from the first week in April till the first week in June, there may be secured from Christmas to the May following a succession of close handsome heads, white as a curd, and equal every way to cauliflowers. This variety, too, has plenty of heart leaves to protect it from bad weather, and is so very hardy that ordinary frosts neither injure nor discolour it. It is a common fault of broccolis that are required to stand the winter, that frost and wet completely spoil them, and therefore such sorts should not be grown. They might

do very well in the south of Europe, but are no use in this fitful clime. In fact, with true seed of the *Cornish Broccoli*, and one good variety of *Cauliflower*, a master of his business is set up for supplies of handsome heads the whole year round, and the man who is not master of his business will not be assisted by selecting a great many sorts, for the more sorts the more perplexity. It strikes me that some of the people who grow the *Cornish* kind in Cornwall, and who keep it true, would do well to send it out direct with some sort of guarantee; for if people send to their seedsmen for it, they are never sure of obtaining it in true character. The *Early Purple Cape* is a most useful kind, and one which I strongly recommend to the cultivator who can enjoy its mild, delicate, buttery flavour without being shocked at its colour. Since I have been in great places, I have been obliged to give it up through the prejudices of the cooks, who will only send to table the whitest of broccolis, and who think more of appearance than the flavour and wholesomeness of their dishes. So with the old hardy *Purple Sprouting*; it is very productive and hardy, and first-rate for large consumers, but I do not grow it; the cooks beat me, and I give in: the head gardener should never be seen fighting with the cook. If we could only cook the cooks, or just mould them to a reasonable shape in their tastes and fancies, we should be happy; but it is amongst the most notable of the many imperfections of the present state of society, that the cooks do not study how to do justice to the skill of the gardener, but the gardener is compelled to humour the whim of the cooks. Ah! I know of many a prime dish that a lord would leap at, but which dare not be mentioned, because the cooks would proceed to extremities, and some of us would be hanged on the nearest Judas tree, or stamped down in our muck-pits by the delicate pressure of feminine fifteen stone. If you should ever be in want of a subject—which I suppose impossible—I hope you will defend the gardeners against the cooks, or could you not by a stroke of the pen abolish the cooks altogether?—that would be the threshold of the millennium.

As to growing broccoli, it is easy enough. But I will tell you a point that the experience of years has taught me, and that is to *have it in good ground from the very first*. Some gardeners think any starved bit of ground good enough for a seed-bed, and the consequence is that the plants are in a poor state all through their infancy, and they never thoroughly recover, no matter how rich the soil into which they are transplanted. I have noticed that plants put out from a poor and neglected seed-bed into deeply trenched and abundantly manured soil, gave very good heads, but those from a mellow, nourishing, and cleanly kept seed-bed were far in advance of them, showing that broccolis, like children, should be well treated from the first, and that no good training in after-years will make amends for neglect in youth. Farmers are beginning to discover this, for the men who make money on fat cattle are those who feed liberally from the first, not those who buy lean cattle that have never known a land of plenty. These last never improve as they ought by good living; they swallow oilcake and corn and good hay, but make flesh so slowly that half the food is wasted on them. Oh, here is a lesson for all who are interested in the development of organic forms, whether animals or plants, and the end of it is that if we aim at perfection, we must teach, train, and feed well from the day of birth. Treat broccolis in this way, and you shall see that my advice is not at guess-work; I guess at nothing, and shall consider all this prosy talk as useful if in any one garden the cultivator succeeds in doubling the gross weight of his broccoli crop through the little hints I can offer him. I say, then, prepare a nice seed-bed, dig in plenty of thoroughly rotten dung, break the clods, and make the surface rather fine. Do not be in a hurry to sow the seed, because if it has to struggle for its life against east winds and morning frosts there will be loss instead of gain by early sowing; and, lastly, keep the plot well weeded, and at every opportunity prick out on to another well-prepared piece of ground the forwardest plants from every batch you sow.

As to soil, the broccoli is not at all particular, but it must have plenty of food. If you can't manure well, don't grow broccoli at all: it's a mockery of kitchen gardening. The private grower wants a succession, not a glut, therefore he should be always planting out a few from the beginning of June till the end of August, in ground deeply dug and heavily manured. It is a crop that comes in well as peas, spinach, beans, early potatoes, &c., &c., are taken off the ground, but I don't like to plant broccoli or cauliflower immediately after any kind of cabbage; it is bad practice. Some writers talk about giving broccoli liquid manure. Now I am not fastidious, but I protest against anything nasty being brought into such close relationship with the dinner-table. Confound it! let the broccoli have good ground, well manured, and there is no need of liquid manure. Those people who are for liquid manuring know nothing about the business at all. Why, to liquid manure broccolis in a proper manner would make every head cost half-a-crown near a town, perhaps five shillings in the country. Bah!

give liquid manure to pot plants, and to asparagus and seakale after the season's cutting is over, if you can afford it; but do not attempt to grow a crop of any kind up to the hour of cutting for table by such means: it is a sham crop, and the talking about it merely belongs to the class of fid-fads.

Sow the first broccolis in pans, in a frame or warm house in February, if early supplies are required. If not, begin to sow in the middle of March, and wait till the end of May to sow the main crop. A warm border out of doors is the proper place for the seed-bed after the 1st of March, and those sown earlier in frames must be pricked out on such a border when sufficiently advanced, preparatory to their final planting out. Sow a pinch of Walcheren at the end of May, and another pinch at the end of June, and you will see how these two sowings will serve you usefully. Never allow the seedlings to remain crowding one another, but prick them out to strengthen before final planting; this is far better than transferring them from the seed-bed to the places where they are to fruit. The two moves are better than one. When planting, handle them with care. Do not bruise the leaves or roots, and if any clubs are on the roots nick them off with the thumb-nail, and dust the roots with lime. As for the rest, any one who can grow a cabbage will see what to do, and it is no use my spinning out this paper; so I close by wishing success to all who read this for information, especially young gardeners.

JAMES BARNES.

Bicton.

NEW MODE OF GRAFTING THE VINE.

The uncertainty and inconvenience of the customary mode of cleft-grafting the grape vine are known to all who have practised it, and the only course of practice that has been discovered tending to increased certainty is that which consists in cutting the stock close over to the ground, and covering the work with earth.

M. Auguste Boisselot, arboriculteur of Nantes, has sought a

Grefte Boisselot.

remedy for these inconveniences, and after many years of experiment has attained complete success.

Here is the method. He cleaves the stock between two bifurcations. It is no matter at what height of the stock this is done. Into the cleft he introduces the graft, cut as for ordinary cleft-grafting. It is then bound up with a strong ligature and grafting wax. He next binds the two branches of the bifurcation at two or three eyes above the cleft; and in the spring, as the sap rises, he pinches back the young shoots, causing thereby a flow of sap into the graft. He does not cut off the two stumps of the stock until the autumn following the insertion, by which time the graft is well developed.

The experiences of M. Boisselot have sufficiently demonstrated that this mode of grafting is nearly infallible. It offers the utmost advantages to the cultivator, especially as a graft can be inserted wherever there is a bifurcation, hence affording the power to place a number of grafts on the same stock. The sudden suppression by means of the knife of the whole of the vine above ground is always prejudicial to the root-action, and the "Grefte Boisselot" is free from this objection. Another important advantage attending it is that if the graft does not prosper, nothing is lost, for the branches of the bifurcation will produce their fruit the same, and

the stock will not suffer more than from the check to which it is subjected by the ordinary process of cutting down.

The horticultural journals of France have given publicity to this invention, and rendered justice to its inventor. The Imperial and Central Society of Horticulture of France has been occupied at several of its meetings in the consideration of the subject, and M. Duchartre, the secretary general, testified, at one of its recent meetings, that he had practised this new mode of grafting with success.

The "Grefte Boisselot" may be practised at every season of the year, but its inventor recommends—and with reason—that the autumn should be preferred, the best time of all being when the leaves of the vine begin to turn yellow.

We consider this invention as an immense service rendered to the culture of the vine. A diagram explanatory of the process is subjoined. It represents a graft made on the 6th of October 1864, and which commenced to grow in June, 1865.

Rue St. Maurice, Monplaisir, Lyons.

JEAN SISLEY.

A BED OF STOCKS.

The growing of Stocks is usually made a very mysterious matter by small pretenders in horticultural literature, as if it required familiarity with some cabala to become expert in the treatment of them. I can call to mind papers that I have read in my early days that I then thought masterpieces of logic and description, but which I now look upon as being vanities. Thus, I remember five-and-twenty years ago, an infallible rule for distinguishing between double and single stocks in the seed-leaf was made public. Of course it profited nobody; perhaps it befooled many; and certainly ensured for its author some degree of deserved contempt. No human being possesses discernment sufficient for distinguishing, while in the seed-leaf, the plants which are to produce single from those that are to produce double flowers, though the faculty would be worth hundreds of pounds annually to market growers, many of whom make a leading feature of stocks, for the simple reason that they sell well. Everywhere amongst writers there is a tendency to make much more of a subject of this sort than there is any need for, and the endeavour to make much leads them to propose complicated modes of procedure; and the unhappy followers of leaders of this sort constitute a large aggregate of people who can't do it. Stocks, asters, balsams, and indeed showy annual and biennial flowers generally, are rising in popular esteem; they are emerging from behind the cloud, or the cloud, rather, is clearing away,—the cloud that has for some years past obscured them; the cloud compounded of illusions respecting geraniums, verbenas, and calceolarias as the be-all and end-all of human hopes and labours in the flower garden. Consequently it is time once more to put people in the right track for growing these things; and as they are old friends of mine, and I can handle them as well as I have ever seen them handled, I shall first touch upon them to such an extent as the state of the case appears to render necessary, premising that, if these subjects are to be treated practically and truthfully, there is really very little to be said about them.

Now, for a bed of stocks, we want in the first place a piece of ground good enough for cauliflowers. It ought to be deeply dug and well manured, and if prepared before winter and left rough, will do far better than if made ready only just before the time of planting. This is not everywhere possible, especially in small gardens; so, if there is no ridged up piece ready now, go to work at once, lay out the bed for stocks, dig deep and manure liberally, and leave the surface rough. There is no mystery about this part of the business, and for practical gardeners it may be summed up thus—*plant in good ground.*

Stocks may be sown at any time during March and April, and again they may be sown in August to stand the winter. But there is some virtue in particular days, and my day to sow seed for a bed of spring-sown stocks is March 20th, and if the 20th happened to be a Sunday, I should sow on the 19th, and not one day earlier. As to quantities and sorts, every one must judge for himself: I shall say presently a word on the sorts I prefer. The sowing should be in pots or pans, in light rich soil. I use quite one half of melon-bed manure rotted to powder. Put the seed-pans in a cold frame and shnt up. Never start the seed in heat, and always give air, but with caution, from the moment the plants appear in the seed-pans. Give more and more air as the plants acquire strength; water moderately, and always in the early part of the day; and take care they do not get a touch of frost or have to endure a deluge of rain. In all this there is nothing more required than ordinary, and it may be summed up thus—*sow in cold frame on or about the 20th of March.*

The planting out is of course a very simple affair, and if you make it otherwise, you fail more or less. If you find in any book directions for pricking out to strengthen, and a series of transplantings to make the plants stubby, burn the book and follow me. First make the bed ready by spreading over it about three inches of

rotten manure (you remember that the bed has been already prepared by manuring and deep digging), and dig it all over half a spade deep or so; the object now being to make a nice mellow nourishing top crust, the importance of which you will see in a moment. The second week in April is soon enough to do this, and when done you may begin planting as weather and time will allow; and *ceteris paribus*, the earlier you plant the better. Draw drills on the surface of the bed just as in sowing any kind of small seeds, let the drills be rather deeper than usual, and plant in these drills rather thick, say two inches apart. Success turns upon the time at which this planting is done; and the golden rule should be to plant as soon as the plants are large enough to handle, and never to transplant afterwards. Let them crowd and starve in the seed-pans, or give them a series of transplantings, and the flowers will be trash, that is, as compared with such bouncing spikes as you will obtain by following these instructions. As to the operation, it may be useful to beginners to say that a bit of stick should be used to lift the plants out of the pans, and to pierce holes in the drills for them, and press the soil down when inserted. A quick workman would lift them out in little patches, and lay them towards the left hand. He would take a few in his left hand, and presenting one between finger and thumb, would at the same moment make a hole with the right hand, thrust the plant into it with the left hand, and close up with the right. The knack may soon be learnt, and this perhaps is enough said about it. The end of it all for the practical man is, *plant them out as small as possible, rather thick, and in drills a little below the general level.*

Management must depend on weather. In case of dreadful weather, such as is possible in this horrid clime, even so late as the middle of May, protect them from frost by some clean extemporaneous method. Twice I have lost plantations of stocks by sharp frosts occurring a few days after they were planted out. There is not much risk, but loss is possible. I know of nothing better than peasticks or prunings of evergreens laid over the bed, or stuck about it in a sloping manner. To sprinkle litter is very effectual, but messy. In case of hot dry weather, give water frequently. In case of nice warm showery weather, let them alone. Keep the ground clear of weeds, and occasionally have a turn at thinning, taking out weak-looking plants. Continue to thin as fast as they begin to crowd each other, and make it a rule to pull out all that show flower first, for the worst of them are the most precocious. In due time there will be a show of flower all over the bed, and the last thinning must be done. Now thin them to such distances as will assure a rich effect without undue crowding, and sort over the thinnings and pot a lot of the best, or plant them in the borders, or give them away. Having finished the thinning at the moment when there is a general glimmer of colour all over the bed, give a good soaking of liquid manure, and leave the rest to nature. This part of the story may be summed up thus—*keep the plantation clean, and promote a free growth, and thin out from time to time, destroying all those that first show flower.*

Now as to the sorts. I could scarcely wish for finer stocks than I had last year from a sample labelled "Scarlet ten-week," sent me by Messrs. E. G. Henderson. They were treated exactly according to the foregoing routine with one slight exception, and they flowered magnificently. They were planted a foot apart in the first instance, and all were allowed to flower; and there was about one in ten single, and the rest were double. I imagine this was English-saved seed; at all events, I should always prefer English seed of the *Scarlet ten-week*, and also of the *Scarlet, White, and Purple Intermediate*, and the noble old *Brompton*, which might be taken in hand for the sake of its bold appearance all the winter, now that winter furnishing of flower-beds is a subject that attracts a little attention. The *German dwarf Bouquet* and the *German large-flowering pyramidal* are fine, but no one needs so many colours as are offered, and I should be content with what are described as *flesh-colour, scarlet, blood-red, rose, and canary*. As for the blues, they too often produce a complaint bearing that name in the mind of the cultivator, for in any dozen of them we may find two nice purples and ten muddy mixtures of bad red, indigo, and brown. Some of the yellows are fine: the one I prefer is the *canary colour*; but the *wallflower-leaved sulphur* is beautiful both in its shiny leaves and its thumping, spiky, fragrant flowers. There are very few places in the world, or at least in England, where a fine display of first-rate stocks may be seen. But I know of one where, for several years past, the annual exhibition of stocks has been something surprising. Any of our friends who would like to see the result of masterly treatment of the stock, are advised to pay a visit at the proper time to the nursery of Mr. John Fraser, Lea-Bridge Road. It is a strange thing that the real country nurseries are frequented by amateurs during autumn and winter, when there is nothing to be seen, and buying is all that can be done; but in the height of summer, when the collections are in full splendour, visitors are few and far between. It is so here; and Mr. John Fraser grows these stocks therefore for his sole enjoyment only. The flower-shows are no doubt the principal cause of the

neglect by amateurs of nursery displays; but this particular display is so peculiar and so praiseworthy, that I hope many of our friends will make a note of it, and at the proper time break in upon Mr. Fraser's quiet and share a little of his joy. S. H.

HARDY WINTER GREENS.

As the Fearnought Cabbage and hybrid varieties of Brussels Sprouts sent out by us are likely to be more appreciated in future than they have yet been, owing to their extreme hardness, having stood the late severe frosts without the slightest injury, while many of the other Brassicas have been utterly destroyed, we would venture to throw out a hint which may prove advantageous to such of your readers as may wish to grow them. In many cases new vegetables are grown at great disadvantage, particularly the first year of their introduction, owing to the cultivator not being acquainted with the treatment they require, and are often discarded as being useless and unworthy of a place in the garden without further trial.

The Fearnought Cabbage if not sown early will produce heads as open as Coleworts, but if sown in the first or second week of March, and planted out in due time, it will have nice firm heads before the winter sets in, and will keep longer without bursting than any other of the Brassica tribe, remaining perfectly sound till the early summer cabbage comes in. Although when growing its appearance is coarse, the flavour is much superior to that of the early dwarf cabbages.

The Dalmeny Sprouts should also be sown as early as possible, or as soon as the ground will admit; if delayed too long, they will not form the cabbage heads on the top. The same treatment is also requisite for the successful cultivation of the Albert Sprouts and New Dwarf Sprouting Ulm Savoy.—STUART AND MEIN, Kelso, N.B.

[It is impossible to overrate the value of the *Dalmeny Sprouts, Albert Sprouts, and Fearnought Cabbage*. During the severe weather in January last they were less injured by the frost than any other winter greens, on a piece of ground where there were at least five-and-twenty sorts standing side by side. But here is an example of the influence of climate. Messrs. S. and M., of Kelso, advise early sowing. At Stoke Newington, near London, last year none of these were sown till quite the second week in April, and they hearted so early in the autumn that a considerable number lost their heads when we should have preferred to keep them. It is impossible to lay down rules generally applicable for seed-sowing; nevertheless Messrs. S. and M. are right in the main, for the best winter greens of all kinds are those from early sowings—that is to say, early for the district. We think that south of Nottingham the first week in April is early enough to sow them, but further north the date must be earlier in proportion to increase of latitude.—Ed.]

WELLINGTONIAS AT HOME.—The following, from a Californian paper, is worth quoting as a sample of the curiosities of the subject:—Dr. C. T. Jackson not long since visited the Mammoth Tree Grove, and estimated the height of the principal trees. Dr. Jackson also seems to have usurped the liberty of bestowing names upon these monarchs of the forest, after having ascertained their altitude. The following is an extract from his note-book, which was recently read before the California Academy of Natural Sciences:—

Names of the Trees.	Height in feet.	Circumference 6 feet above the roots.
T. Starr King	366	50
General Scott	327	45
General Jackson	320	42
Two Sentinels	315	..
Salem Witch	310	..
Trinity	308	48
Mother of the Forest	305	63
Wm. C. Bryant	305	40
Henry W. Beecher	291	45
Granite State	286	50
General Washington	284	52
Abraham Lincoln	281	44
Bay State	280	48
Old Kentucky	277	45
Empire State	275	50
Andrew Johnson	273	32
Daniel Webster	270	49
Mother and Son	269	64
Edward Everett	265	40
Pride of the Forest	260	50
Vermont	259	41
John Torrey	259	35
Arbor-vite Queen	258	31
Beauty of the Forest	258	..
Henry Clay	241	44
Asa Gray, nearly as high as the John Torrey.		

Cool, very cool! Years after the discovery of a great natural curiosity, a pensioned peripatetic visits this wonder of nature and bestows names right and left to suit his own notions of propriety. Himself a fanatic, he endeavours to transmit to posterity, by a durable memorial, the names of some of his fellow-fanatics. And this he attempts at the expense, not only of the truth, but the decency of history. The loftiest of these children of the woods he names T. Starr King. Whatever may have been the virtues of this distinguished deceased, the great majority of the American people have not yet been "educated up" to the belief that he was a greater man than George Washington; yet Dr. Jackson tilts him up to the head of the heap, and tries to fasten his name upon a tree 366 feet high, while he lets Mr. Washington down to only 284 feet in altitude. Now we think Washington was a better and a greater man than T. Starr King. There are many other men in America, and elsewhere, who think likewise. The former was a patriot in our opinion—the latter was a sectionalist, a fanatic, and nothing else. Our wonder is, that *Mister Jackson* did not degrade General Scott and General Jackson to a lower level in his expressed opinion, than that of Wm. C. Bryant and Henry Ward Beecher.

Calendar.

WORK FOR WEEK COMMENCING MARCH 9.

Kitchen Garden and Frame Ground.

SPINACH that has stood through the winter will now begin to grow, and will be useful. It will be well to take the first supplies by thinning the plants, so as to allow those that remain plenty of room to make large leaves. On good land they ought to be left at least a foot apart, and at this distance they will meet with the first impulse of growing weather. Sow a few rows of round-seeded spinach at once.

RHUBARB will be greatly benefited by heavy waterings with liquid manure during dry weather. Like all other docks, it likes moisture and good living. If new plantations are wanted for next season, now is the time to make them. Choose deep rich soil, trench and manure, and plant stout pieces of good varieties, with one plump eye to each; rub off any small side-eyes, and in dividing do as little damage to the roots as possible. If not gathered from at all this season, these plants will be very strong next spring; but if gathered from too soon they will never be strong.

ASPARAGUS beds to be lightly pointed over, and dressed with salt at the rate of a pound and a half to every square yard. Sow seed for new beds. On cold clays the soil may be greatly improved for asparagus by burning and returning the burnt clay in the proportion of one-fourth of the whole bulk. But if sand can be had in plenty at a cheap rate, it is best to use it liberally, and instead of digging the sand in on the piece marked out, set a labourer to draw off from various parts of the ground the surface soil to about an inch or so deep; this will be finely pulverised, and will break up with the sand and dung much better than the stubborn staple.

CELERY sown early will now require to be pricked out into boxes on a slight hotbed. The plan we have followed many years with the first crop is to pot them separately in sixty-sized pots, which they completely fill with roots by the time the weather will allow of their being planted out, and then they suffer no check. Sow now for the main crop.

PEAS AND BEANS to be earthed up as usual. If slugs abound, strew wood-ashes or soot along the rows. Sow again, if required, for succession. Knight's Dwarf Marrow and Taylor's Longpod beans are good sorts for a late supply.

POTATOES may be planted for main crops. The sets should be hard, dark-green; the sprouts short and purple; the soil in a dry state, and quite pulverulent; the sets trenched in—the dibber is a destroyer. Cover only three or four inches, so that the hoeing between and earthing-up will add to their depth, and cover them in the end with about seven inches of soil. In spite of the disease, potatoes are grown more extensively than ever, both as a farm and garden crop.

CABBAGE crops of all kinds to be cleared off the ground as soon as possible, to make room for spring produce. Brussels sprouts, savoys, Scotch kale, &c., will now begin to cumber the ground. If there is any fear of the supply running short till round spinach and other early vegetables come in, plant the best of the old stumps in a quarter by themselves, and they will furnish a few good gatherings. Otherwise consign them to the muck-pit, to rot into manure. See recent notes on this subject. Sow at once Rosette Colewort, Early York, and Sbilling's Queen, also Grange's White and Purple Broccoli, and London Market Broccoli.

WINTER GREENS.—A small sowing may be made this week of Brussels sprouts, Scotch kale, Chou de Milan, and savoy, for early winter supply.

HOTBEDS.—Among the necessary operations, the first is to get the material, and plenty of it; less than a two-horse load is of little use, and the more the better. Another important condition is to get it in time—not less than a fortnight before it is intended to make the bed or beds. If a large quantity is obtained, have it a month before making into beds; the reason of this is that fresh stable dung heats violently for a time, but soon cools if not turned over. It is of the first importance that the dung should be turned over with a fork once every four or five days for a fortnight at least. Where it presents any appearance of dryness, let it be wetted gently, not drenched with pails of water thrown on it, which would wash out much of its most useful property. The result of this preparation is, the material acquires a shortness and consistency adaptable to the maintenance of a steady, lasting heat, which would not be obtained without it. In forming hotbeds, it should be borne in mind that, for the culture of cucumbers, melons, and for any such purposes, nothing can surpass solid beds made in the true orthodox fashion; that is, measure the length and breadth of the frame, mark out the ground for the bed, allowing a foot each way beyond the measurement of the frame, to ensure the frame resting upon it, then drive a stake firmly into the ground at each corner; these will serve as a guide. Then proceed to build the bed, shaking the dung well out as it is laid, beating it down with the fork; and remember that this process should not be hurried over; if it takes longer to do a thing well than it does to do it anyhow, that time will be found to be well spent in the long-run; do the work carefully, if you would avoid the risk of failure at first starting. Having built up the bed (which, if done before April, should be about four feet high), it is not advisable to put on the frame the same day, as any sudden weight causes a sudden rise in the temperature; but in case of heavy rains, which would cool the bed considerably, it should be covered by some means, either with straw-litter, mats, or a tarpaulin. The second or third day the frame may be put on, the fourth day a bushel or so of soil may be put in a hill under the centre of each light, and the fifth or sixth day the seeds may be sown or the plants put in. If all has been managed as described, everything will go on satisfactorily.

Flower Garden.

VERBENA VENOSA is a very easy subject to manage, for it is only needful to keep the roots safe from frost from the time of taking up till now to secure any amount of stock of it. Put the roots into shallow boxes, and place them in a propagating heat at once.

TULIPS must now be looked over with a sharp eye, as their faults and failings will be to a great extent apparent. Canker must be removed by means of a sharp knife; water lodging in the hearts of the plants can be drawn out with a syringe on which is fixed a "nose" instead of a "rose," or by means of a pointed stick with a sponge on it. Weeds are beginning to show on the beds, and must be eradicated; and the whole surface must be loosened an inch and a half deep when the ground is dry and the sun shining.

HERBACEOUS LOBELIAS of the fulgens section are not thought much of

in the present day, and hence we only occasionally see them in borders, and then usually in tufts a foot high with short spikes of middling flowers. Even then they are beautiful, but mere weeds compared with the specimens the herbaceous growers of the old school used to produce, the stools measuring eighteen inches to two feet through, and the spikes, rising six feet high, like wands, adorned their whole length with loops of crimson silk or satin. We cannot in a calendar say much about specialities of cultivation, but allusions to any are perhaps quite fair. Those who have herbaceous Lobelias in store pots may now divide them, and pot them separately; they ought to fill their new pots with roots before being planted out.

ROCKERY.—This a good time to purchase ferns, alpines, &c., for rockeries, and generally speaking to make, mend, and improve rockeries. Plants inserted now will have time to get established in their positions before the heat of summer, which is generally very trying to plants in these structures, owing to the insufficiency of earth. There can be no difficulty about the kinds of plants suitable, as lists have been so frequently given in these pages; for the present it will be advisable to name the following as eminently serviceable: *Alyssum saxatile*, *Arabis albidia*, *Aubrieta purpurea*, *Corydalis lutea*, *Isolemonium cœruleum*, *Draba aizoides*, *Phlox setacea*, *subulata*, and *procumbens*; *Saponaria ocymoides* (snails are intensely fond of this pretty thing), *Campanula garganica* and *rotundifolia*, *Saxifragas* of sorts, the most important being *cymbalaria*, *crassifolia*, *hypnoides*, and *geraniifolia*; also, *Sedums* of sorts, the best being *acris*, *populifolium*, *glaucum*, *fabarum*, *aizoon*, and *deltoides*; also hardy *Staticeæ*, a few species of *Thymus*, the pretty *Dielytra eximia*, all the species and varieties of *Funkia*, and *Sempervivum*. The majority of these require a good body of soil to root into, or they will perish during the heat of the summer; and in every rockery there ought to be a body of soil, for there are not many plants that, like the houseleek, can live without it.

PANSIES in beds and borders to be spread out, and their long stems covered to within two inches of the point of each. These will all root and bloom finely. Sow seed in shallow pans filled with light rich compost.

AURICULAS to have plenty of water and air, but during driving rains it is best to keep them sheltered. Remove all secondary trusses, and thin the tips of the trusses left for blooming.

BOX EDGINGS made now will do far better than in autumn. If the weather is dry after planting, keep newly planted box well watered, as if a few plants die, the unightly gaps are not easily mended in the height of summer.

CARNATIONS AND PICOTEES.—The best time to repot them is in March. The compost should comprise two-thirds loam from rotted turfs, and one-third decomposed cow manure, with a little sand, if the loam does not partake of it. This should be prepared in November, and be frequently turned over during the winter, and be kept from heavy rains. The size of pot best to bloom them in is 12-inch. There should be plenty of drainage, viz., about two inches of broken crocks, over which spread a thin layer of coarse-riddled dry soil, and then fill the pots about two-thirds with the compost. The next thing is to turn out the plants carefully from the pots they were wintered in. Keep the hall entire, and remove at least an inch of the top soil from each. Aphides may be frequently found in concealment there, and the removal of the top soil clears them away. If the small fibres of the roots round the ball are matted very much, and injured by the frost, pare some of them lightly off with a sharp knife, being careful not to cut or disturb the strong roots or loosen the ball of the earth. Next place them erect in the centre, if for one plant; but if they are potted two or three in a pot, place them symmetrically as far from each other as from the side of the pot, leaving the plants about the same depth in the soil as they were during the winter. If they are largish in the leg or stem, an inch deeper will not be amiss; give them a shake by a lift and a gentle hit upon the ground or potting-bench, to settle the soil regularly in the pots, and to prevent its sinking much afterwards. Water them lightly, but enough to reach the bottom of the pots, and continue to do so regularly as they need it, early in the morning, till the end of May, and after that date water them in the evening and morning, if required. Having finished the potting, remove them to a sheltered situation, if you have it, where the wind cannot visit them too roughly, as violent winds do more injury to them than anything else they have to contend with. Those plants that require it may be secured to a small hazel twig, but as they increase in height, they should have sticks about four feet long, pointed at the end, to which the flowering shoots should be tied.

Fruit Garden and Orchard House.

GRAFTING is generally performed too soon. There is plenty of time yet for all who have delayed the operation, but the acions should have been taken some time since and heeled in. If scions are wanted, secure them at once, and give the preference to young hard shoots that have not yet started. The operation of grafting may be variously performed with the best prospect of success from the present time till the end of May. We suppose the reader to be acquainted with the principles of grafting, though perhaps not familiar with the practice. One important principle in grafting must always be borne in mind, and that is, that the graft and the stock must be nearly allied. If a graft of an apple be put on the roots of a beech, it will not grow: the beech and the apple are not related. A graft of a medlar put on the roots of a hawthorn will grow: the medlar and the thorn are related as members of the same family. It will suffice to say that there must be a botanical affinity between graft and stock: a pear may be grafted on a pear, a quince, or a thorn; an apple on an apple, a peach on a plum, &c., &c. As a rule, we choose for the stock a variety which makes roots freely, and for the graft a variety which produces a valuable fruit. It is essential that, as we cannot very well hasten the growth of the stock, we must retard the growth of the scion, because the stock should be in advance of the scion when the latter is put on. If the acion is in advance of the stock—that is, in a more forward state of growth—it is pretty sure to periah, because it will require sap to nourish its expanding leaves, and cannot have sap till a junction is effected; whereas if it is in arrear of the growth of the stock, it is likely to succeed if properly grafted, because the sap of the stock will bring about a junction before the graft requires nourishment, and by that time the stock will be able to supply it. The junction between graft and stock takes place on the outside, and therefore it is necessary that when the graft is put on it should fit the stock bark to bark—on both sides if possible, but on one side certainly. The more neatly the scion is fitted on the better, and the greater the extent of externally united surfaces the better, consistently with fitting on the scion so that it will remain firm in

its place with very little support. Therefore it is that whip, tongue, and saddle grafting are so largely practised; these are, in fact, the best methods for ordinary purposes, because the scion is so cut as to sit firmly in its place with the least risk of being shifted, and also because there is a great extent of corresponding portions of the inner bark of both scion and stock brought into contact. *Whip Grafting.*—Supposing apple grafts to be put on clean young stocks, cut the stocks as in fig. 1, and the scions as in fig. 2. That is to say, take one of the stocks and cut off its head to within six inches of the ground, leaving the top at a clean slant at an angle of about 50°, thus: Now remove from one side a slice, by a firm cut upwards, at least an inch and a half long, by which cut very little of the wood must be cut away, and the surface of the wound must be smooth and clean. The stock is now ready, and resembles fig. 1, where the dotted lines show a portion of the head which has been

Fig. 1.

removed. Now take the scion in the left hand, cut it square across at the lower end, and cut the end to a deep notch, short on one side and as long on the other as the side slice taken from the stock, and it will resemble fig. 2, where, as before, the dotted lines show the part that has been cut away. We have here nine buds beside the top bud. Five of these will be plenty, so cut off the top close over the bud at A, and it is ready. Fit it on in a clean and neat manner, as in fig. 3. Next take some broad strands of bast, and working from the centre of a length of bast, and using both hands to pass the two ends right and left, tie it firmly, but not tight enough to squeeze the bark, and either paint the tie with mastic or cover it with grafting clay, so as to form a small ball to hide the bast altogether, for the

Fig. 2.

Fig. 3.

exclusion of the atmosphere. Another method is to remove two inches or so of earth from the stem, and cut the stem over as close down to the roots as will leave sufficient of it above ground for convenience of making the proper incisions. Proceed as before, fit on the graft, tie with bast, and return the earth, and then heap up more earth in a cone over the tie, so as to leave the top of the graft peeping out of the hillock. This obviates the use of grafting clay; but as it is not so convenient to work close to the ground, the proper style of cutting should be acquired by cutting higher up. *Tongue Grafting.*—This mode is adapted for thicker stocks than any small graft will fit. Instead of the short side or shoulder on which the graft rests in fig. 3, there is a notch made with the chisel, and smoothed with the knife, in the top of the stock. To fit this we cut a graft as in fig. 4, where there is not only a similar deep notch, as in the former case, but a side slice has been taken off at A; this when turned round allows of a contact of the edges of the corresponding barks, as at A in fig. 5, where the graft is put on, and is ready to be tied. Sometimes, however, there is no need to take the slice from the scion as at A in fig. 4, but it may be cut as in the first example, and as shown in fig. 6, which has a very long tongue, and if well put on will take quickly and prove a strong junction. *Shoulder Grafting* is a variation of the tongue as in fig. 7.

GRAFTING MASTICS.—In order to protect the parts of a graft from the action of the atmosphere, and other things likely to injure them, various mastics are used; one kind, known as *Saint Fiacre's Ointment*, is chiefly composed of clay. Take strong adhesive loam or clay, and knead it to

Fig. 4.

Fig. 5.

the consistency of soft-soap. Take also some horse droppings, and rub them well through a riddle of half-inch mesh. Mix the two ingredients with fresh cow-dung, all in equal parts, and knead till of a uniform consistency. When grafting, the operator should have at hand a vessel full of finely-riddled ashes, and after the clay is bound round the scion, the hands should be dipped in the ashes; this will enable the operator to give the whole a neat finish. This clay mastic has the inconvenience of being liable to be washed away by heavy showers, and of cracking when very dry, by which means it ceases to be a sufficient protection to the tender graft. When used upon apple trees it is likely to harbour insects, which of course prove hurtful to the graft, and endanger its success. Grafting wax possesses none of these inconveniences. There are several sorts, some of which are used cold and some hot. Most of the cold mastics are in the form of a soft paste, and have the unpleasant inconvenience of sticking to the fingers of the operator. Those which are used hot are therefore generally preferred, notwithstanding the extra trouble of heating them. They should be used just warm enough to be liquid, but care should be taken that the mixture is not hot enough to injure the tissues of the tree. A small brush or a spatula may be used to spread it with. The mastic of

Fig. 6.

Fig. 7.

which the following is the composition is always used hot. For 100 parts by weight—

Black pitch	28	parts
Burgundy pitch	28	"
Beeswax	16	"
Grease	14	"
Yellow ochre	14	"

100

Another: Take 4 ounces of pitch, 4 ounces of resin, 2 ounces of hog's-lard, and 2 ounces of beeswax; put them altogether into a pipkin, and dissolve them over a slow fire, and it will form an excellent grafting wax. By spreading some of this mixture on paper it makes the grafting paper. The French make very good grafting wax by mixing together equal quantities of beeswax and resin, and adding as much tallow as will cause it to dissolve at a low temperature.

Greenhouse and Conservatory.

TENDER ANNUALS ought to be growing freely now in a genial atmosphere, and very near the glass. If they are running up with long legs,

prick them out and plant them in the fresh soil deep enough to cure their legginess. Too much heat and insufficient light will cause them to be drawn, and if they are much drawn, they will never flower well.

FUCHSIAS are growing finely now, and plenty of cuttings may be got without distressing the old plants; in fact, the stoppings of shoots will do, for it matters not how short and soft the cuttings are; they always root instantly if put into sand in a nice heat. It is no use to grow Fuchsias slowly; let them have the warmest berth possible, with plenty of syringe and only a little air.

CAMELLIAS out of bloom to have a higher temperature and a moist atmosphere, to promote the new growth. Any that seriously want a shift may have it now; but the general shifting is best delayed till the wood is ripe or ripening.

CINERARIAS are now coming to their full splendour, and must have constant attention. Neglect of watering will cause the lower leaves to shrivel, and too much water will cause the colours of the blooms to run. Use manure-water twice a week. Tie out specimens in good time. Those only just showing their trusses may have a shift, so as to form fine plants late in the season.

PELARGONIUMS for exhibition require constant attention to keep the foliage in perfect health, and to tie out and train as needful. Give plenty of air to strong plants, and manure-water, rather weak, every five or six days. Shift young plants. Never stop and shift at the same time.

CHRYSANTHEMUMS to be propagated now in quantity. Those who neglected to strike cuttings in November for specimen plants have now not a moment to lose. But some gain may be made by pushing them on in a warm house, and stopping as soon as it is safe to do so, to get a good set of side-breaks.

BEDDING PLANTS.—Cuttings put in now will bear more heat than those put in a month ago, as vegetation is more active with the advance of the season. There is plenty of time now to raise stock of Verbenas, Petunias, Fuchsias, and Lobelias, and they will bear a moist temperature of 75° to advantage. Pot off into thumb-pots newly-struck cuttings as soon as they begin to make new growth at the points. Young plants that want a shift to larger pots, and which are to be stopped to make them bushy, should be stopped first, and the repotting delayed till the side-shoots begin to break.

SUCCULENTS are usually kept dry all winter, and have supplies of water in very small quantities as they commence their seasonal growth. Though easily kept in windows and ordinary greenhouses, they rarely flower unless they have some special care at this time of year. If any of them want larger pots, they should now be shifted, and the soil used should be a mixture of lime rubbish, broken bricks, turfy loam, and a little cow-dung, with plenty of drainage crocks in the bottoms of the pots. As a rule, large pots are not favourable to their prosperity, so they should never be shifted unless the old soil is worn out and the plants have grown to a size out of proportion to the pots they are in. All the Cacti and Mesembryanthemums, &c., now stored on greenhouse shelves, should be dressed on the surface with rotten dung, and be placed over a moderate bottom-heat, with small supplies of water to set them growing. Plenty of light, plenty of water, when in free growth, and a generous temperature, are requisite to produce a good bloom.

Forcing Pit.

FRUIT HOUSE.—Plums and peaches must be carefully managed while the fruits are stoning. Any excess of fire-heat or water, or cold draughts, will cause the fruit to fall at that critical period. As they commence swelling after the stoning period, the heat may be slightly raised, and the trees to have frequent showers from the syringe. Peaches in the early house to have a temperature by day of 75° to 80°; by night, 55°. On dull days the day temperature not to rise above 65°.

FRENCH BEANS in the forcing-house must be kept very near the light, and have a brisk temperature. Give air early on fine mornings while the plants are moderately dry, to promote the setting of the fruit. Crops that have been cut from to have the help of soot-water, or a solution of sulphate of ammonia, half a ounce to the gallon, to promote a luxuriant growth.

CUCUMBERS.—It will be more difficult now to keep the heat of bearing beds up to the mark than it has been all the winter, for the east winds will cool them more rapidly than the mild rains we have had so much of. Linings will now be of great value, and as the weather is bright, a brisker heat may be kept up with great benefit to the plants, especially if the pit is kept constantly moist. In giving air, guard against the entrance of parching cold wind; a mat hung over will allow of an exchange of atmosphere through it without permitting the entrance of a killing draught.

FIGS in the house are now swelling their fruit nicely, and require plenty of water. If allowed to root through their pots into rotten leaves and other such plunge material, liquid manure will perhaps not be needed. If in pots, and not plunged, they must have liquid manure. It is certainly better to confine the roots of figs than to give them free scope in a border; but the pot system is often overdone to the extent of starving the trees, so that they never give the returns or present the appearance they ought to. Perhaps the most satisfactory way is to plant out in brick pits, so as to have the roots under command, and at the same time give them food enough.

VINES to be thinned of their superfluous bunches as soon as the berries are fairly set, and the thinning to be done with a bold hand; for any larger crop than the vines can bring to perfection without severely taxing their strength will entail weakness of constitution. Thin the shoots, always ensuring the natural shade of leaves for the bunches. Inside borders to be kept warm, and be liberally watered. As vines set their fruit syringe them briskly to wash away the remains of the flowers, after which do not use the syringe, but supply atmospheric moisture by means of pans of water on the flues, and watering the floor of the house. In all vineries there should be water-troughs over the pipes for this purpose.

MELONS to be grown in frames to be ridged out at once, so as to have the full benefit of sun-heat when the temperature of the beds is declining, and to ensure a perfect ripening of the fruit. Ridge them out on a good depth of strong loam, without manure.

PINES to have the help of manure-water while swelling their fruit, to be discontinued when the fruit begins to change colour. Succession plants to have a shift, and no manure-water till they have made plenty of good roots. Atmospheric moisture will greatly help them if the temperature is kept at 70°.

SPRING FLOWERS: EFFECTS OF THE FROST IN EDINBURGH.

At a recent meeting of the Botanical Society of Edinburgh, Mr. M'Nab presented a report on the state of open-air vegetation in the Royal Botanic Garden. He said: My last report to the Botanical Society was on the 16th of January, 1867. The ground at the time, and for nearly two weeks afterwards, was covered with snow, and a succession of frosts of different degrees of intensity prevailed, but on no occasion did the thermometer fall so low as on the night of the 4th of January, when it indicated 11°, being 21° below the freezing point. The lowest thermometer markings since the 16th of January are as follow: On the 17th, 20th, 21st, 22d, and 23d of January falling respectively to 24°, 23°, 20°, 15°, and 25°; the lowest since the beginning of February being on the 11th, when the morning temperature marked 32°. The highest morning temperatures since the January meeting were on the 24th, 25th, 28th, and 29th, indicating respectively 37°, 36°, 43°, and 41°; while the highest since February commenced were on the 1st, 2d, 3d, 4th, 9th, and 13th, marking 39°, 37°, 36°, 47°, 37°, and 47°. As much discussion has recently taken place about the time the thermometer was at its lowest during the month of January, the following readings of the thermometer in the Edinburgh Botanic Garden may be worthy of notice, and tend in some districts to settle this point. During the early part of the night of the 4th of January the thermometer was observed to be gradually falling, and had every appearance of reaching a very low point. It fell to 11° at 9.30, and remained the same till 11.30; at 12 o'clock it rose to 14°, at 3 a.m. to 20°, and at 7 a.m. to 27°. Readings on register thermometers are generally taken at daylight during the winter months, as the lowest points are generally about that time. If it had not been for a constant watch over the thermometer during the above night, we would not have known the time it was at the lowest point, and marked it as if on the morning of the 5th. During the time the second snowstorm came on, the ground was hard with frost, which greatly retarded the progress of our spring herbaceous vegetation. The first snowdrop seen in bloom was on the 31st day of January, and that only on a south exposed grass bank, where the frost got speedily out; but in all other situations throughout the garden it was the 5th day of February before they began to show flowers profusely. The first flower of *Eranthis hyemalis* and *Hepatica triloba* appeared on the 2d of February; *Sisyrinchium grandiflorum* on the 4th of February; *Leucojum vernum* and *Galanthus plicatus* on the 5th of February; *Helleborus purpurascens* and *Arabis alba* on the 6th of February; and *Crocus susianus* on the 11th of February. It appears that the temperature of the 4th of January was much lower in many parts of England than what we experienced, even below what was observed on the morning of the 24th of December, 1860, when —6° was the lowest point indicated. In some parts of England the thermometer during the January frost fell from 4° to 10° below zero, and the damage to vegetation as notified in the leading horticultural journals, has been very considerable. The extent of mischief done by frost does not show to its fullest extent for days, and often weeks, after, the injury depending much on the state of the weather. If followed by a few warm sunny days, the mischief done will show itself at once; but if dull, cloudy, and cold weather should follow, weeks often pass before the full extent of the losses can be ascertained.

As far as we can yet judge of the amount of damage done at Edinburgh, it may be considered as trifling. Amongst herbaceous or suffruticose plants, stocks and wallflowers which stood above the level of the snow have suffered severely. The various species of *Tritomas* have been much cut up. *Veronica Andersonii*, *lobelioides*, and *salicifolia* are also much injured, as well as pentstemons and perennial lupines.

Amongst shrubby plants, none of the conifers show any symptoms of injury. The leaves of the common laurustinus in some localities are more or less blackened, as well as the leaves of some of the delicate hybrid rhododendrons. The young and tender leaves of variegated hollies are likewise much browned. The plants which as yet show the greatest amount of injury are the cork-trees and evergreen oaks; the leaves appear very white and much twisted, particularly the leaves of those trees partially injured but not cut down after the frost of 1860. The cut down specimens soon became covered on the surface of the ground with a dense growth of healthy vigorous shoots; none of these in the meantime show signs of injury. The *Garrya elliptica*, which was in full flower on the 4th of January, looks very bad in some places, all the flowers destroyed, and the leaves on many of the plants look very sickly. Some of the soft growths on roses are a little injured, but the ordinary spring pruning will soon put them right again.

ON THE ROBIN REDBREAST.

The red-brestid robbing is a burd muchly doted onto by seminary girls and poets.

Gentlemen farmers also encurridge the robbing becoss he swallereth insecx when he canit get sno or anything els tu eat.

Bnt practikle farmers and fruit-growers begin to don't see it.

I was onest a gentleman farmist.

I am not so gentil as I wuz.

I go for rele farming, making my pile of manoor and raisin things to eat.

I used to listen for the robbing's matting lay and his evening carol, but I've found out that he singed only to seduce femal robbings, and that where he ct five insecx he ct quarts of cherries, strawberries, currants, raspberries, and ceter, and then pitch inter the mellerest bartlett pairs.

I found that my fruit crop agreed to wewl with Mr. Robbing's crop.

His wobbling to his femal friends at evening didn't pay for his gobbling choice fruit all day.

And so, my friends, when the sweto redbrest gets fat on the eggpensive products of northern gardens, and flocks southward to fill unsentimentil pot pies, I bid him adoo without regret.—*Hornsey Hornet*.

An officer who was on intimate terms with the Prince of Orange, one day asked him the purpose of an extraordinary march they were making. "Will you keep the secret?" asked the Prince. The officer hastened to assure his master that he was incapable of abusing his confidence. "I believe you," replied the Prince; "but if you possess the gift of keeping a secret, the same blessing has also been conferred on me."

At a parish school examination, when the question was asked, "Why did the children of Israel make a golden calf?" a sharp little fellow replied, "Because they hadn't gold enough to mnke a bull."

HINTS FOR AMATEURS.

Large Onions—When the beds are formed, tramp them heavily, and roll them firmly. On this compact surface sow the seed, and cover it the usual depth with a rich compost. The bulbs, instead of sinking, will spread superficially to a good size.

Liquid Manure, for growing vegetable crops, may be given twice each week, and for developing flowers, as soon as the calyx or flower-cup begins to burst, it should be applied but once a week. A cloudy atmosphere is the best condition for giving water, and early in the evening the best period in summer months. The liquid which soaks from common farm and poultry yards, with some soot added, is the cheapest; but where such is not procurable add 1 lb. guano to 30 gallons of water, and about a spadeful of soot, the latter tied up in a coarse cloth or bag to prevent it from swimming on the surface of the water. This mixture will make a liquid manure fit for all the ornamental grass-feeding plants, as polargoniums, salvias, fuchsias, calceolarias, achimenes, clerodendrons, &c., &c. To prevent drawing off, or using the water in a turbid state, drain it off as clear as possible. The soot is an essential ingredient as a manure, and as an antidote to insects.

Manures, or fertilizing ingredients, should be kept in a usable condition, as near as component parts admit.

Soft Water.—Where rain or soft water is not procurable for watering plants, it should be known that caustic lime is a useful element in reducing its hardness. The proportions are, one of lime-water to five of common water, which reduces the hardness of water to the same degree as that of water after having been boiled; or 1 lb. of chalk calcined will produce 9 ozs. of caustic lime, which will make 40 gallons of the lime water, and be sufficient to mix with 560 gallons of ordinary London pipe-water.

When Watering, particularly newly planted crops, in dry weather give a good soaking of water at the roots, and in all mild weather sprinkle over the whole plant at the same time, to prevent excessive evaporation.

Surface Mulching, with manure or enriched soil, is of great advantage, and essential for ensuring good crops on poor soils.

Moss on Fruit Trees.—Sprinkle each tree freely with water in the months of February and March, and in this state scatter a thick coating of quicklime as equally as possible over the branches. By this application the moss is effectually eradicated. Lime of the most caustic quality will be the most powerful.

Cleanliness from all weeds and rubbish should be considered as essential amongst growing vegetable crops in the kitchen garden, as amongst the more fragile productions of the flower garden. In both cases, every green leaf of a weed or intruding plant is abstracting the "life blood" of the soil, both from the present and following crop.

Rest.—Directly the crops are off, trench and ridge the ground well up. Turn over all spare ground to the action of the air, &c.

Surface Hoeing amongst all crops should, for its benefits, be uniformly attended to, in admitting the free action of the atmospherical agencies of light, heat, &c., upon vegetation, and without which, in a proportionate degree, plants will not grow, flowers will not expand, nor fruits ripen.

To Kill Weeds on Gravel Walks.—Dissolve one pound of powdered arsenic in three gallons of cold water, boil and keep stirring it, then add seven additional gallons of cold water, and two pounds of crushed soda; stir the whole well in the boiler, and apply it to the walks in dry weather from March until May, by a watering pot with a proportioned rose. The above quantity will suffice for 25 square yards or more. This mixture has been very successfully applied in one of the most extensive gardens in Yorkshire, where it required one man a fortnight to go over the whole. For wide carriage drives the liquid was conveyed by one of Fleming's garden engines, with a tap behind, care being taken to keep the hot water from the box edging or grass margins, by laying an inclined board, with supports behind, as a shield or cover to the grass, &c., and moving progressively for a given distance in front as required.

To Kill Plantains on Grass.—Apply a drop of sulphuric acid from the end of a plant label or slender stick to the heart or crown of each plant in dry weather, and in five minutes the leaves turn yellow, then black, and in two days the weed disappears.

Economical Plant or Skrub Labels.—Take common bricklayers' laths of the double size or thickness, and cut into required lengths of 10 to 12 or 14 inches: smooth the sides with as little waste as possible, and shave off smoothly about 6 or 8 inches of the best front face with a sharp knife, finishing the lower end by cutting the sides to a short, sharp, wedge-like point, and then bevel it off reversely, by cutting it from the front and back face, which is better than leaving it with a sharp, wedge-like point. Procure a few pounds of pitch or tar, and form a brisk fire between loose piled bricks, upon which boil the tar, and dip the lower ends of the labels in the tar, whilst boiling, to the depth required of the labels to enter into the ground (6 or 8 inches). Allow the pitch to dry, and then surface the smooth face of each with a thin coat of well-mixed paint, and lay them by till required. When used, the smooth surface requires a second coat of paint, which should be written upon within a quarter or half an hour after being applied, otherwise it is difficult to make the writing legible. When the second coat of paint is allowed to dry, it is impracticable to impress writing, and in such instances the labels must be refaced. The best round carpenters' or joiners' pencils should be used for prominent plain figures or letters.

Honeydew.—This is produced by the soot fungus (*Torula fumago*), a terrible pest. For its eradication try dusting the parts affected with flour of sulphur, or newly-slaked lime, or washing with fresh made lime-water. It soon ruins plants if not immediately checked.

Importance of Drainage to Flowers and Plants.—Defective drainage deprives the roots of proper nourishment, subjects them to a chilling temperature, and forces them to absorb a vitiated fluid.

Making Charcoal and Wood Ashes.—Lumps of wood (for charcoal), and refuse branches, sticks, &c., (for wood ashes), should be packed close in the form of a mound or cone, and thus set on fire, kept closely covered with good tough grass-cloths about 3 inches thick. The heap should be watched day and night during combustion, adding an additional clod if requisite to prevent the escape of flame. When the charcoal is made, the heap should be opened and cooled with water.

EPITAPH FOR A CHILD.—The gardener was one day walking among his flower beds; suddenly he stopped and cried, "Who has done this?—who has plucked my choicest flower?" He was answered, "The Master gathered it." The gardener held his peace.

CULTIVATION OF PASSIFLORA QUADRANGULARIS.

Passiflora Quadrangularis is the species with which I have had greatest experience, and it is of it I now particularly speak. While I was foreman at Floors Castle, we had one planted in the corner of one of the pine stoves, which alone subsisted upon what it could procure amongst the tanner's bark used for plugging the pine pots, and from the atmosphere and moisture of the house; and I venture to say that under no other treatment whatever could greater success be expected. The bark requiring to be removed at least once a year, necessitated the roots being entirely bared, and a change of materials offered to it; but although I have seen this done when a crop of fruit was hanging—and sometimes the roots lay exposed for a couple of days—yet I never saw it suffer in the least from such ill usage: the flow of sap seemed as regular, the leaves retaining their wonted healthy appearance, and the fruit as plump as though nothing had occurred. Besides this, the pines were regularly overhauled four times a year, which necessitated a little fresh tan being added every time, and of course new holes had to be made for the pots, the making of which often brought us into contact with its roots, which were often twisted and broken; yet all this had no effect either upon the fruitfulness or the vigour of the plant—in fact, I often thought that it proved good for it. As I have already stated, it was planted in the corner of this bed, from whence it was trained upon a stake till it reached wires made for its reception under the west light of the house. The first year I saw it, it was trained to these wires after the ordinary manner—that is to say, it had five or six shoots trained right to the top of the light, and spurred after the same fashion as a grape vine; in this way it yielded a light crop of excellent fruit. When pruning time came, I was instructed by Mr. Rose to treat it upon quite a different principle, and upon this principle of pruning, I am convinced, hangs the great secret of its after productiveness. He instructed me to remove all the permanent canes except one, and this one I was to train horizontally along the bottom wire the desired length—which was five feet, the width of the light. I did so, and when it began to make shoots, all were removed save six, which were placed equidistant, and led to the top of the sash, about twelve feet; here they were pinched, and in a few days every bud of this young shoot sent forth a lateral with a flower-bud in each of the first four or five joints. The first one was always selected for impregnation, and the shoot pinched at the next joint, and we were always particular to select the time when we could procure the greatest abundance of flowers, within a week or so, for this operation, as we observed that, generally speaking, few fruit could be set after about a dozen of the first impregnated ones had reached the size of pigeons' eggs. No other care was bestowed upon it after this, except to go over it once a week or so and pinch all the laterals back to the nearest bud beyond the fruit from whence it had sprung. This first crop was generally all removed by the middle of July, and all that was necessary was to prune back these laterals to one bud, which again immediately sent forth shoots, with flower-buds, which just required the same treatment as their predecessors.

As before stated, the plant only occupied one light, which was 5 feet wide, and upon this it was trained about 12 feet, so that the surface it covered was about 60 square feet, and the produce from the two crops was seldom less than 200 fruit every season. I remember Mr. Eyles, of South Kensington, seeing it in 1863, when ninety-seven fruit were hanging upon it nearly ripe, and he was utterly astonished, and remarked that it was the most extraordinary crop he had ever seen, yet at this time there could not be less than twenty fruit removed from it. After the second crop of fruit had been all removed, and the tree was ready for pruning, we entirely removed the six main shoots which filled the light, cutting them right back to within one eye of the horizontal stem upon the lowest wire, much in the same fashion as when pruning a vine. The tree rested very little, so that in a few weeks the young shoots were again starting from the stem, and a few weeks more saw them reach to the top of the light, once more to odorate and beautify the house, only to give place to another abundant crop of this handsome and excellent fruit, which one day or other will command a more prominent position upon the dessert-table than it does at the present time. Now, whether the same success would have attended it had it been planted in any of the various compositions usually used I cannot say, yet I think it will be interesting to many to know it succeeded so well under this; and this much I will say, that if I were to have a house expressly for them, I should use no other materials than tanner's bark. I may also remark that this plant seldom got any water at the roots—in fact, sometimes not for months. It was, however, regularly syringed every day along with the pines. We also fruited *P. edulis* very well in the plant stove. This was treated after the ordinary fashion, and in a composition of peat, loam, charcoal, and old mushroom dung. It is, however, much easier managed than the former, and not nearly so shy of fruiting under ordinary circumstances.—James M. Millan, *Erskine, in Farmer.*

FOOD VALUE OF THE POTATO.

There is, probably, no other vegetable food, except wheaten bread, of which so much can be fairly said in its favour. Its merits, however, vary much with the kind of seed, the period of maturity, and the soil in which they are grown. That kind should be preferred which becomes mealy on boiling, and which, when well cooked, can be thoroughly crushed with the finger. The potato which is known as "waxy," and those which remain somewhat hard when boiled, do not digest so readily as the mealy kind, but for that very reason they are said to be more satisfying. It is not material in reference to nourishment whether the potato be boiled or roasted, since in both methods it should be well cooked. In point of economy and convenience, however, it has been found better to boil than to roast them; for whilst the loss in boiling upon 1 lb. of potatoes scarcely exceeds half an ounce, that in the most careful roasting is 2 oz. to 3 oz. It is also more economical to cook them in their skins, and to peel them immediately before they are eaten; but this is not convenient in many families, and the colour of the potato is not quite so agreeable as that of those which have been boiled after peeling. When they are peeled before boiling, and particularly when they are small, and the operation is performed carelessly, from one-third to one-fourth of the whole weight of the potato is lost, and if there be no pig to eat the peelings the whole is wasted; whilst the weight of the peel which is removed after boiling would not amount to more than 1 oz. in the pound. When potatoes have been roasted, the loss in weight from the skin and drying is more than one-fourth of the weight before cooking. An average sample of potato, after it has been

peeled, contains 11 per cent. of carbon and 0.35 per cent. of nitrogen; and hence in each pound there are 770 grains of carbon and 24 of nitrogen, and it is greatly inferior to bread. The economy of its use depends upon its cost, so that in times when potatoes are sold at $\frac{3}{4}$ d. and 1d. per pound, they are a very dear food as compared with household flour, while they are a very cheap food when produced by the labourer at the cost of the "seed" and the rent of the land. Thus, at $\frac{3}{4}$ d. per lb., only 1,024 grains of carbon and 32 grains of nitrogen will be obtained for 1d.; when the cost is 1d. per pound, the quantities will be reduced to 770 grains and 24 grains. When the labourer, however, can obtain 50 bushels of potatoes from a quarter of an acre of land, at a cost of about 30s. for seed and rent, he will have more than 7 lb. of potatoes for 1d., and the quantity of carbon and nitrogen thus obtained for that sum would be 5,770 grains and 200 grains. If, however, he were to sell a large part of his crop at the market price, he could procure with the money thus obtained far more nutriment in the form of flour than would have been derived from that portion of his potatoes. The weight of potatoes which alone would supply the daily nutriment required by a man would be about 6 lb. in reference to the carbon and 8 lb. in reference to the nitrogen; but when a labourer in the west of Ireland lives upon this he is allowed 10 $\frac{1}{2}$ d. daily, besides a large supply of buttermilk, and as both of these kinds of food are cheap in that locality, the proceeding is even then an economical one.—*Dr. E. Smith's Practical Dietary.*

Literature.

The Intellectual Observer, Review of Natural History, Microscopic Research, and Recreative Science. Vol. X. Groombridge and Sons.—This superbly illustrated and ably edited work maintains its high place, and never in the least flags in interest. The tenth volume is as rich as any of its predecessors in both literary and pictorial attractions; and as representing the progress of discovery and research during the past half year, it is characterized by singular ability and tasteful discretion. Many indeed have been the attempts to "popularize" science, and they have for the most part failed. In the *Intellectual Observer*, popularising has never been aimed at, but a much higher purpose has been served by combining elegance with full and unreserved statements of scientific truths. The result is that the work finds acceptance wherever a better class of reading than the average of periodical works is in request, and in every polished circle or intellectual household this entertaining and thoughtful monthly is held in high favour. In the volume before us there are admirable papers on Ancient Jewelry by Mr. Duthie; on Fungi by the Rev. M. J. Berkeley; on the Kaffirs and Animal Life in South Africa by Dr. Mann and Mr. Chichester; on Prismatic Spectra by A. S. Herschel; on the Growth of Shells by Dr. Woodward; on Infusorial Life by Mr. H. J. Slack and Dr. Jabez Hogg; on the Bell Birds of America by Dr. P. L. Sclater, secretary to the Zoological Society; on the November Meteors by the Hon. Mrs. Ward, A. S. Herschel, and Mr. H. J. Slack; on Planetary Phenomena by the Rev. T. W. Webb and Mr. R. A. Proctor; on the Pheasants of Burmah by Captain Beavan; on the Genus Ficus, and on Parasitical Plants, by Mr. J. R. Jackson, of Kew; on the Chameleon by Mr. Jonathan Couch; on the Genus *Cypripedium* by Mr. Hibberd. Besides these leading subjects, there are numerous delightful records of discovery and travel, notices of inventions, reports of the proceedings of scientific bodies, reviews of books, and gatherings from all the leading scientific journals published in every part of the world. There are twelve coloured plates, in addition to numerous beautiful engravings on wood; particularly worth notice for their beauty are the figures of *Cypripedium Veitchianum*, the American Bell Bird, and the Chameleon. The following extract may interest our readers:—

THE GENUS FICUS.

By J. R. JACKSON, Curator of the Kew Museum.

"Amongst the finest trees of purely tropical scenery, of course still excepting the palms, the members of the genus *Ficus* hold a prominent place. This genus belongs to the natural order *Moraceæ*, and is that also to which our common fig belongs, besides *Morus* itself, which includes the mulberry, *Broussonetia*, the paper mulberry, *Dorstenia*, and others. Though the order is small, it is a most important one, both in an economic point of view, and also in botanical interest. The genus *Ficus* is especially rich in many varied forms of useful products, for beside the fig itself, we have caoutchouc, lac, &c. Whether any of the species are European is a question upon which our best botanical authorities have differed. Lindley says that none of the *Morads* are European, and that the mulberry and common fig have both been brought from the East; other writers consider the fig to belong originally to Asia Minor, Persia, South-Eastern Europe, and North Africa. We can only say that, if not truly indigenous, the plant has become thoroughly naturalized in all the countries mentioned above. The way in which many of the species adapt themselves to circumstances in their mode of growth is peculiar, and very striking to an observer. In many cases we find them twining, and almost enveloping, colossal palm trunks, though they are capable of forming very thick trunks of their own, which frequently bear an immense spreading crown. The magnificent wild fig trees of the East, indeed, are always regarded as the true friends of the sun-scorched traveller, affording as they do such a cool retreat, and such a complete shelter from the sun. Lindley says the genus *Ficus* is one of those which travellers describe as most conducing to the peculiarities of a tropical scene; and, quoting from the 'Annals of Natural History,' he says, 'Mr. Hinds points out the complex appearance of the main stem of many species; their immense horizontal branches, their proportionate lowness, and the vast number of smaller stems in every stage of development—some just protruding from the horizontal limbs, others hanging midway between the leafy canopy and the earth, displaying on each thick rounded extremity an enormous spongiolæ, while many reach the soil, and, having attained strength and size, act as columns to sustain the whole structure.' The best example of this very peculiar provision for supporting so wide-spread a canopy is to be found in the banyan tree. This tree is certainly one of the most famous and interesting of all the East Indian forms of vegetation, and is the best type of the peculiar adaptability of the genus in forming irregular trunks, and that in a manner quite contrary to the usual mode of proceeding in the vegetable world. We all know that one of the laws of plant life is to send its root downwards and its stem upwards, so that the former may take in from the earth the nutriment there stored, while the latter, developing itself by its natural appendages,

performs the important functions of respiration. This, of course, in its infancy, is the case with the banyan; but after it has grown, and formed its crown of foliage by throwing out its branches, and while yet a young tree, these branches perform a double duty; for besides being the support of the leaves, they throw out again downward branches, which reach and strike root in the ground, and then go on growing as true stems, thus forming a support for the spreading mass above. These trees are common all over the East Indies; and to such a size do they grow, that one tree forms a miniature forest in itself. The largest banyan tree is said to be on the banks of the Nerbuddah river, where, for aught we know, it is still growing. Forbes, in his 'Oriental Memoirs,' says the circumference of the tree at the time of writing the account, was nearly 2,000 feet, and the overhanging branches which had not thrown down their props or supports stretched over a much larger area. The tree had as many as 320 main trunks, and over 3,000 smaller ones, and was capable of giving shelter to 7,000 men. These dimensions appear almost fabulous; there is, however, another fine tree at Mhow, which has sixty-eight stout stems, and can give shade, even under a vertical sun, to an immense number of men; indeed, we are constantly told that a regiment of cavalry can conveniently take refuge beneath one. For large assemblies or meetings they form perfect natural tents. It is very certain that these immense trees must be of great age; and we should naturally expect to find a full description of so remarkable an object in the works of the old classic authors. Strabo's description is both minute and accurate, as is also that of Pliny. The banyan has been the theme of poets in more recent times, as well as of travellers and naturalists. Milton beautifully describes it in the following passage—

Branching so broad and long, that in the ground
The bending twigs take root; and daughters grow
About the mother tree; a pillared shade,
High over-arched, with echoing walks between.
There oft the Indian herdsman, shunning heat,
Shelters in cool; and tends his pasturing herds
At loop-holes cut through thicket shade.

And Southey, in his "Curse of Kehama," says—

'Twas a fair scene wherein they stood,
A green and sunny glade amid the wood,
And in the midst an aged banyan grew.
It was a godly sight to see
That venerable tree;
For o'er the lawn, irregularly spread,
Fifty straight columns propped its lofty head!
And many a long depending shoot,
Seeking to strike its root,
Straight, like a plummet, grew towards the ground:
Some on the lower boughs, which crossed their way,
Fixing their bearded fibres round and round,
With many a ring and wild contortion wound;
Some to the passing wind, at times, with sway
Of gentle motion swung;
Others of younger growth, unmoved were hung
Like stone-drops from the cavern's fretted height.
Beneath was smooth and fair to sight;
No weeds nor briars deformed the natural floor;
And through the leafy cope which howered it o'er,
Came gleams of chequered light.
So like a temple did it seem, that there
A pious heart's first impulse would be prayer.

"Though habit has taught us to look upon the root of a plant as that part alone which is buried in the earth, we see there are such things as roots being given off from totally different parts. This occurs mostly, if not entirely, in tropical climates, and is effected greatly by the influence of moisture and shade, considering, of course, that the plants have a natural predilection for forming these aerial, adventitious, or secondary roots. The banyan is a good example of a plant producing aerial roots.

"The structure of a true root, when fully developed, is very similar in all respects to a true stem. The epidermis, however, is without stomate, and the bark is always very thick, owing to the moisture it absorbs from the earth. Thus we find that stems of many plants are capable of forming roots, as is instanced by the growth of plants from cuttings, or by pegging a bent branch down to the ground. In the case of the banyan, so long as the roots are pendent, they derive their nourishment from the parent trunk, but as soon as they reach the ground, the spongiolæ or absorbent parts of their roots become more developed, and strike into the earth, and then begin the necessary functions for increasing their diameter, and supporting the weight of the new foliage above. It is not at all uncommon to see the trunk of the talipot palm (*Corypha umbraculifera*), or the palmyra (*Borassus flabelliformis*), completely encircled by one of these figs. This is caused by the seeds, which are very small, dropping into the axils of the leaves of the palm, where they vegetate, and send their roots downwards, embracing the trunk in their descent. In very old specimens where these aerial roots have extended to a goodly diameter, the palm is seen emerging from the thickness of the fig, as if it was actually one and the same plant. These combinations are considered sacred by the Hindoos, who call them holy marriages. A white, glutinous juice exudes from the stem, which is considered a remedy in toothache; birdlime is also manufactured from it, and an infusion of the bark is said to be a powerful tonic.

"A small but very good specimen of the banyan tree may be seen in the palm house of the Royal Gardens, Kew, and a trunk of the talipot palm, encircled as described, is in the museum of the same establishment.

"The Popul (*Ficus religiosa*, L.) is also a native of the East Indies, and is remarkable for the long tapering points of its leaves, as well as the closely reticulated and strong vascular fibre. The Chinese make very pretty and effective ornaments of these leaves, by removing the cellular tissue or green pulpy matter, and covering the skeleton with a coat of varnish or gelatine, and then painting figures of birds, flowers, &c., on the surface. The ease with which the cellular tissue is removed by macerating, recommends the leaves of this species for the purpose of dissecting or skeletonising for leaf bouquets. Amongst the Hindoos, the poplar-tree is greatly venerated, their belief being that among the branches the goddess Vishnu first saw the light. The plants are, in consequence, frequently to be met with near houses, pagodas, &c., and the natives are very unwilling to cut them down. Birds devour the fruit with avidity; and in their flight, instances have been known of the seeds having fallen into the cracks of buildings, where they have germinated, and caused much damage. They are used in medicine by the native practitioners, as is also the bark. The leaves of the different species vary much in form, those of the poplar being heart-shaped, with the long slender point before spoken of, and seated upon long

and slender petioles; they have a trembling motion in the air, very similar to that of the common aspen. They are a favourite food for silkworms.

"Peculiar as the two species here enumerated are, the most important of the Indian species, in an economic point of view, is *F. elastica*, Roxb. It is a tree growing some thirty or forty feet high, with large oval or oblong leaves, very thick and glossy, and is now well known as a common conservatory and parlour plant. The fruits are arranged in axillary pairs, sessile, or without stalks, not larger than an olive. From this species most, if not all, the caoutchouc or India rubber brought from the East Indies is obtained. We all know how abundantly a white milk flows from the least fracture occasioned to any part of this plant; the prick of a pin upon its stem or thick green leaf will cause it to ooze out, and by exposure to the air become thick and elastic. When collected in its native country for commercial purposes, deep incisions are cut through the bark nearly down to the wood, in a transverse direction, and about a foot apart. The juice flows from these wounds in large quantities, and on coming in contact with the air, forms itself spontaneously into a solid elastic substance, from which a kind of whey or foetid fluid separates. After such a tapping as this, the tree is said to require but a fortnight's rest before it is ready for a similar operation. The presence of caoutchouc or milky juices in plants is a character of many natural orders. Some yield a pure milky fluid which never hardens. The vessels that contain this fluid are called laticiferous tissue, or cinenchyma. They are very minute, the average diameter of one of them not exceeding $\frac{1}{1000}$ of an inch. One of the chief distinctions of these vessels is that they lie in no regular or definite position to the other tissue, and consist of long branching tubes. In their young state they are very thin and hair-like, but as they get older they become large, their sides thicken, and contract in some places and swell in others. This has given rise to an opinion amongst some botanists that they are merely a series of cells, placed end to end, in which the partitions have become absorbed, as there are no divisions through their entire length. The contents of these tubes, called the latex, is not in all plants milky, but sometimes coloured, and at other times quite transparent and colourless. It is always of a granular nature, but its chemical composition varies in different plants; for while some give a perfectly harmless, and even a nutritious milk, others are acrid and narcotic. The cells which contain caoutchouc, and similar juices, must therefore not be confounded with the cells or vessels through which the ordinary nutritive functions of the plant are carried on, nor must the fluid itself be confounded with the sap.

"The common fig (*Ficus carica*, L.) is perhaps the best known of all the species, owing to its valuable fruit. As we have before said, its native country is doubted. The plant is, however, now cultivated to a very large extent in Turkey, and on the shores of the Mediterranean. It is a tree growing in favourable situations to a height of twenty or thirty feet. The plant is so well known in our gardens and greenhouses, that it would be needless to describe it. We may, perhaps, however, be allowed to say a few words about the fruit, as it is a peculiar though a common one. We hear people speak of the 'seeds' of the fig, meaning those little granular sago-like things so numerous inside a fig. These are not seed, which we should soon discover were we to examine them in a green fig. They are each of them a small individual fruit, which in this form is called an achene. The *Ficus carica* is not cultivated for the sake of its flowers, for though it does flower, and that profusely, we venture to doubt if there are many of us who have actually seen the flower. It is not showy, nor is it exposed, as most flowers are, to the air and light. In most of our common fruit-producing plants, we first behold the bud, then the expanded flower, which in time drops away, leaving the fruit to develop itself to the size limited by nature; but in the fig, what we call the fruit is not the produce of one flower, but of many. The fleshy part which we eat is in botanical language called a receptacle. There are, however, various forms of receptacles, and even in the same family to which the fig belongs; thus, for instance, in *Dorstenia*, we have an open, somewhat irregular square receptacle, slightly turned up at the edges like a tray. In this genus the flowers are exposed, but are still numerous as in the fig. Another common example of an open receptacle is to be found in the sunflower, and we have only to bring up the sides, and nearly unite them at the top, and we shall have the same form of receptacle as the fig, namely, a hollow one, with the inflorescence inside instead of out. This inflorescence is of both sexes, else fertilization could not take place; and it is worth noticing the provision of nature in placing the male flowers near the orifice, at the apex of the fruit, while the females are seated in the concave part below; by this arrangement, the pollen from the male flowers, in dropping, is more sure to fall on the stigmas of the females, as the figs themselves, in their earlier stages of formation, and when the flowers are fully expanded, are nearly always more or less upright upon the stalks which bear them, seldom drooping until after fertilization has taken place, and the receptacle has become swollen. It frequently occurs, however, that the stamens are imperfect and no pollen formed. A practice called caprification has been resorted to in the East to provide for this natural deficiency. A number of wild figs, which are often infested with a species of cynips, are strung on threads and hung above the cultivated ones. When the insects escape from the former, they enter the latter by the orifice at the apex, and so, by carrying the pollen grains upon their wings or otherwise, fertilize the female flowers. This system, however, is not so generally adopted as formerly, as it is now considered to injure the quality of the figs. It appears to have been clearly understood and practised by the ancients, as it is fully described by Theophrastus and Pliny. The introduction of the fig into this country is by some writers attributed to the Romans, and by others not till the early part of the sixteenth century, on the return of Cardinal Pole from Italy. The very trees which he brought, and which were planted in the garden of Lambeth Palace, are said to have flourished for 300 years. There is, or at least was until very recently, several fine examples of very old fig trees in the kingdom, some of them of very great diameter, proving that even in our climate the fig is capable of thriving, though a severe frost is liable to do it great injury. The south coast of England, however, appears to agree with it, and standard trees have been known to produce fruit in tolerable abundance.

"There is yet another species of this interesting genus which we must just notice before taking leave of it, and this is the sycamore or sycamore fig (*F. Sycamorus*, L.) This is supposed by some to be identical with the tree into which Zachus climbed. If this is so, and the tree is to be identified with that mentioned in many passages of Scripture, it must have been of great importance among the Jews, though the fruit is small, and hardly worth eating compared with that of the common fig. The light

wood of this plant is said to be almost imperishable, and served to make the cases of the Egyptian mummies. The genus includes about 200 species, but the few we have described are the most important in an economic point of view, the most peculiar, and the types of the genus generally."

Correspondence.

THE RECENT FROST AT PENCAITLAND, EAST LoTHIAN.—Meteorology for January, 1867, 284 feet above sea level. Thermometer: max. 50°; min. 2°; range, 52°; mean, 29°. Barometer: high, 29.85; low, 28.38; range, 1.47 inches; very unsteady. Rain-fall: 3.65 in 1866; 2.73 in 1865; 1.50 in 1864; 0.60 in 1863; 3.63 in 1862; 2.07 in 1861; 1.20 inches less rain falls in the East Lothian than in any other part of Scotland. Days when the temperature was below 20° during the month: 1st, -2°, 31° of frost; 2nd, 0, zero. 32° of frost; 3rd, 5°; 4th, 4°; 5th, 6°; 14th, 18°; 15th, 11°; 18th, 16°; 21st, 13°; 22nd, 6°. Snow about 15 inches deep on the level surface; stubbles and long straw of grass quite covered; a greater quantity of snow than has fallen at one time for upwards of fifteen years—that is, since my residence in this locality. Shrubs killed at Tynholm (some of them will spring again from the root).—Common laurel, *laurustinus roseum*, *acubas*, common whin. Roses, all varieties; a few escaped. Brassica tribe, all perished. Shrubs, &c., injured.—Portugal laurel, cotoneasters trained on walls, common holly, American arbor vitæ, &c. Lowest temperature in 1861—January 4th, 7°; 5th, 5°; 8th, 3°. Lowest temperature in 1860—December 24th, -7°, 39° of frost; 25th, 2°; 26th, -5°, 37° of frost; 28th, 8°, 29th, 8°. The destruction of shrubs and plants was unprecedented in Scotland, including all that have been killed and injured this winter, and a large number of others, among which were the *Aranearias*. The only locality that I heard of where they escaped was at Preston Grange, St. George Salties, near Prestonpans, 6 miles from here, contiguous to the sea beach, and only a few feet above it.—*Garrya elliptica*, cedar of Lebanon, bays, all varieties. Hollies and laurels of very ancient growth at Winton Castle, and all along the east coast. Broom, privet, &c., *laburnum*, walnut, box, and yew, slightly injured. Even the common ivy and large trees of different kinds were killed. At an elevation above the sea of 350 feet and upwards, evergreens quite uninjured, as they are this year also. Lowest temperature in 1855—February 16th, 5°; 17th, 3°, 29° of frost. Common laurel injured, and the whin killed, which it has been three times during the last fifteen years.

ARTHUR TREVELYAN, J.P.

SEED CATALOGUES AND THEIR USES.—Nothing is of so much importance to a gardener as that of being certain in his purchases to ensure sound seed and correct to name, thus in every way according with the descriptions given of them in the seed catalogues that are issued annually. Anything the reverse of this is a serious disappointment to him, and more especially as regards the cultivation of vegetables, for in some degree his crops may be considered his character. The seed catalogues put forth in the present day have appended to them a vast amount of practical information, and are very minute in describing the properties of the popular varieties of vegetables and flowers in their several classes; and I am convinced that if my brother gardeners would give some attention to the advice therein given for promoting the germination of some of the kinds of seed which by ordinary methods often prove difficult to vegetate, they would be much benefited, and the seedsman would not be, as he often is, blamed for disposing of bad seed. It is surprising to me how few consider their recommendations worthy of adoption. I will endeavour to illustrate my observation by referring to the rearing of *Primulas* from seed—and here I can say, without exaggeration, that on many occasions have gardeners said to me, "I cannot get it to grow," and followed this remark by a hint that the seed must have been bad. Now, it has happened in more than one instance that I myself have obtained seed in the same year from the firms which supplied those who complained that they could not make it grow—firms considered famous for their strain of this particular flower. But by my adhering to the directions published in the catalogues, I have accomplished all I desired, and there was no reason for me to complain. Invariably my reply has been to such complaints, "Did you read the practical remarks that are appended to the seed list?" The answer has been generally, "No." Now who is to be blamed in this matter? Certainly not the seedsman, for both at expense and trouble he has obtained from a thoroughly practical source instructions for our guidance. We will now proceed to say something respecting the vegetable portion; and let me ask my friends if they have read carefully during the past year in this magazine the result of our worthy Editor's trial of the various kinds of peas. If so, in giving their various orders for their usual quantities this season, they may, both now and in the future, save themselves a deal of labour and trouble by selecting the more suitable varieties for their purpose from the Editor's trial list. A word of advice to young gardeners (and old too, if they like), and that is, Do not purchase seeds solely on account of their cheapness, because good seed costs much labour that the stock may be sound and its character preserved. Again, I do not think it advisable (I write from experience) to purchase the collections as advertised—say, "No. 1, supply for small," or "No. 2, for large garden." Not that they do not contain good seeds, but they either contain less or else an excess of what is actually required for the demands of the family, for it must be borne in mind that the consumption of a particular vegetable is greater with some than with others. Then, I say, select your sorts and quantities from the general list; and if your garden is of limited extent, do not confuse yourself with too many varieties of any particular species; but, aside from novelty, have regard to those that are the most profitable cropping combined with flavour, only introducing those sorts with whose merits you are not conversant with caution. But, on the other hand, if you have sufficient extent of ground at your command, then variety will be the more acceptable.

JOHN F. M'ELROY.

THE ODOURS OF FLOWERS AND OF THE TEMPLE.—There is infinite economy but no waste in the administration of nature; and in the vast and complicated relationships which prevail amongst the objects of creation, each one has innumerable duties to perform. Fragrance is poured forth upon the earth only during those months in which its presence is needed, and while it charms the sense, conserves the life on which the sense depends. In these respects it resembles the incense which God commanded the Jewish priest to burn on the altar, which was placed "before the veil of the tabernacle that was by the ark of the testimony, before the mercy-seat that was over the testimony," where He promised to "meet with him." But when was the incense commanded to be burned, and for what purposes

were the sweet odours to be diffused? Not continuously or at capricious intervals, during prayer, praise, or sacrifice. Not when the high priest moved from one spot to another, or made his entrances and exits before the people. Nor was it for useless purposes of unmeaning pomp and pride, like those to which it is put in the modern churches of Rome. Aaron was to "burn sweet incense every morning when he dressed the lamps;" and again Aaron was to burn incense when he lighted the lamps at even. Such were the times: when the lamps were dressed, and an offensive odour proceeded from them; and again, when the lamps were lighted, and partial ignition produced similarly disagreeable effects. In the sultry deserts of Arabia, where these ordinances were first promulgated, oils and fatty matters are with difficulty kept from putrescence. The burning of incense at the times of trimming and lighting the lamps was, therefore, a sanitary regulation of much importance; for thereby the smells of rancid oils were agreeably dissipated in the perfumes of "stacti," "onyca," "galbanum," and "frankincense," "tempered together, pure and holy," just as in the tabernacle of nature similar important offices, and many others of a beneficent character, are discharged by sweetly-scented flowers.

ALICE.

A RULE IN JOB-GARDENING.—Amateur submits a case as follows: "Will you tell me whether it is usual for nurserymen to instruct their men to refuse, when they are told to put in seed not purchased of their master? A man hired of a nurseryman was working for me a few days since, who, when I gave him seeds to sow, told me that his master would not allow him to do so unless they had come from him. Thinking this must be a mistake, I went over and saw the nurseryman, who corroborated his man's statement, having his refusal upon a trade-rule, which, from his showing, appeared to be a well recognised one in his trade. If you would favour me with the advantage of your extensive experience in the matter, you would oblige."

[Nurserymen who send out workmen and make a system of job-gardening, do commonly observe such a rule as is set forth in the foregoing letter. The rule, however, is not followed with any degree of severity; some are more obliging than others, and the question is not raised in every case of the workman being required to handle either plants or seeds purchased elsewhere than of the contracting nurseryman. We may say of it that it is a rule generally but not implicitly followed. This reply is, however, insufficient. Amateur is evidently desirous of an opinion as to the justice of the rule, and on that head we offer a few remarks. We venture, then, to pronounce the rule highly objectionable, because if the owner of a garden takes any real interest, he will be constantly desiring to make purchases on his own account of seeds and plants, and he ought to be free to do as he pleases. Nurserymen who job largely do the work well, and supply seeds and plants of good quality, yet their customers are not in agreeable circumstances; they are as it were under the thumb of the master gardener, and may very properly complain if they take a whim of purchasing for themselves. But, on the other hand, the nurseryman has ready an argument which, according to the existing premises, is unanswerable. He says, "The work is not worth my doing unless I can supply all seeds and plants that are wanted." This is true. Everybody knows that to let out mere labour is an unprofitable business. What is the price usually charged per day for such work? It is 3s. 6d. to 4s. It is impossible for the master to make a profit if he pays his men wages that they can live upon, and gives the customer credit, and keeps his books correctly, and takes his share of losses on his trade throughout. He may indeed protest that he would not send out men at all, except it were as a means of promoting the sale of plants and seeds, from which he can derive some profit; and if he allows one customer to buy a few seeds, he must allow another; and if occasional small purchases be winked at in the spirit of accommodation, he may lose his selling trade altogether, and find himself a loser by letting out labour only. For those who are dissatisfied with such a state of things, the only course is to alter the premises. The contract must be entered into upon different conditions, and there must be a clear understanding as to the purchase of plants and seeds and other garden necessaries. In conclusion, we take this opportunity of remarking that the rate per day commonly charged for skilled workmen sent on to job-work, is too low to afford the master a fair profit on the business, and the men a fair wage for a fair day's work. Jobbing is beset with vexations to all parties, and the rate per day is doubtless the root of the evil. Some masters pay only half-a-crown a day, and employ any men they can get, even if they have never before handled a spade in their lives; and they aver that, owing to the low figure at which they do the work, and the long credit they are obliged to give, this is the only safe method of procedure. As for the customers, they get bad work, and sometimes something worse; but the price paid for labour is at the bottom of it all.]

Replies to Queries.

Planting Vinery.—J. S. L.—For your forcing-house 10 feet long, with about 9 feet length of rafter, one permanent vine would be sufficient; and this should be planted in a border in front of the house, and brought through the centre of the front wall. Train up three canes; one up the centre, and one at two feet from each end. A Black Hamburgh will best stand your smoky atmosphere (Liverpool). Until the permanent vine is established, introduce pot vines if you like into your heated bed; indeed, it might be worth considering whether these would not answer your purpose better than a permanent vine. In that case, you might, in addition to Black Hamburgh, introduce White Frontignan. In either case, you must rest your vines in winter,—the one by removal from the house to cooler quarters, leaving your forcing-house available for other uses; the other by shutting off heat and opening the ventilators. Excavate 2½ feet deep for your border, by 12 feet wide; throw in six inches of brickbats, and place a drain along the front, if any danger of water lodging. Upon these place sods or stable litter, to prevent the soil of the border mixing with the drainage; upon that place three feet in depth of soil, which may be composed as follows: If the present surface soil is good, take one part, and two parts of fresh surface soil from a pasture, the other part to consist of half a part of old lumpy mortar and brick rubbish, and half a part of good old stable or cowhouse dung well rotted; to this add 2cwt. of ½-inch bones. Cover your border in autumn and winter with tiles or shutters, to throw off rain.

Primula Seed.—Eusinge.—Place the selected plants in a light airy house, keep them fairly but not abundantly supplied with water, take the seed from a few of the first and best flowers only, and nip out all the flower-buds that follow. Seed from the best strains is often rendered of inferior quality through allowing the plants to produce too much. There is no occasion for artificial impregnation unless a cross is desired.

Aucuba Seed.—Amicus had best remove the seeds from the berries, and sow them at once two inches deep in mellow loam, in a shady place in the open ground. If this is not convenient, they may be sown in boxes; but the boxes should be placed in a shady spot out of doors, as preferable to housing them. The plants will probably appear about June, and at the end of September it would be advisable to pot them, and put them in frames or pits for the winter.

Roses in Windows.—Inquirer.—Roses are not good window plants. But they may be placed in windows while blooming, and should be removed to the open air when the bloom is past, except in the case of the little fairy roses, which make very pretty window plants for all seasons. A south window is indispensable; and to prevent them becoming sickly and drawn, every opportunity should be taken to put them out in mild showers, and indeed at every convenient time. But care should be taken not to expose them to frost, cutting winds, or a burning sun. We have seen Lawrencian roses kept in health and beauty for years as window plants, by constantly helping them in the way indicated, and avoiding all extremes. Weak guano-water will benefit pot-roses when the pots are full of roots, but is not wanted when they have been newly potted.

Weeping Birch.—J. W. T.—The weeping and other varieties of fir are multiplied by grafting or inarching. Where there is only one tree, and it is desired to multiply it, young trees of common birch should be planted round it as stocks, and the variety may then be inarched very conveniently. If this course of procedure is not convenient, grafting must be resorted to; this being the best season for the operation.

Araucaria.—J. G.—Your handsome tree must have been badly used in the process of transplanting. The plan you propose to follow will not improve it; probably the admixture of a large proportion of rotted dung would be very injurious. Make a mixture of good mellow loam and tough lumps of turfy peat; have it carefully lifted, and plant it without raising it above the level. Let the stuff be carefully thrust in amongst the roots with the hand, not stamped in with the heel of a boot, as is the way with men accustomed only to bedding and ditching, and by all means avoid making perforations in the tree; do not mutilate it at all. What was said last year about stopping araucarias was intended for scientific arboriculturists, who are deeply interested in such matters, not for those who are as beginners or mere lookers-on in such matters. If you lift and replant your tree at once, it will have a good chance of making a fair growth this season. Send the ivy-leaves as you propose; one of each sort

Constant Reader is advised to apply to Messrs. Jas. Carter and Co.

Chrysanthemums.—J. J.—Cuttings are made from January to April, and for some purposes as late as June or July. Those made in February and March usually produce the finest plants, and of necessity they are then struck in heat, which must be moderate, and the cuttings must be in full daylight. In stopping, the point of the shoot is pinched out with the fingers; but if a shoot takes the lead and goes ahead of all the rest, it may be cut back two or three or more joints, and made a cutting of.

Stephanotis floribunda.—T. R.—A plant intended for exhibition in August next, should now be growing freely in a good bottom-heat, as advised in the calendar of operations.

Zonale Geranium Seed.—South Molton.—To flower next year, sow the seed in June or July next. They may be flowered in great part this year, if sown alone and put in a stove and kept there till the beginning of May, getting them potted single as soon as they have two or three leaves beyond the seed-leaves. The soil for the seed-pans should be loam and leaf-mould in a not too fine condition; there should in fact be plenty of lumps in it as large as beans, the finest part of course on the top. A good compost to pot the young plants in is one composed of equal parts loam, peat, and dung rotted to powder with a half part of silver sand. Shift them from size to size as fast as they fill their pots with roots, and keep them always near the glass in the sunniest house you have. Sow the seed of Tiger Lily in a pan filled with a mixture of loam and leaf-mould or peat, and place it in a pit or frame. Keep it moist and shaded till the plants appear.

Verbenas.—Sbropshire asks too large a question to be disposed of in Replies, and therefore her letter has been handed down to a contributor who can deal with it in *extenso* and in the most practical manner.

Strawberry Forcing.—Sibley.—You appear to have spotted your crop by the fear of feeding the plants well. We have frequently advised, both in "Operations" and otherwise, the plunging of the pots in leaves or dung and the abundant use of the water-pot. We have never seen potted strawberries fruit so finely as when they were allowed to root through the pots into some highly nutritious material, such, for example, as a bed of good manure. But plunging in leaves is better than nothing, because of the constantly moist condition of the roots. Plenty of air and full exposure to light are essential to success; no strawberry fit to eat was ever grown in the dark, or even in a much shaded position.

Grafting.—C. C.—You will find all you need in the way of reply to your queries in this week's "Operations." Many readers do not appear to pay sufficient attention to this department, in which to a great extent their wants are anticipated.

EFFECTS OF THE FROST.

A curious illustration of the severity of the late frost has, among others, been brought under our notice by an eminent physician, who is a great admirer of plants. In a greenhouse, together with Sikkims and other plants, was a small specimen of, to our mind, the most beautiful and interesting of its kind yet introduced—*Rhododendron Javanicum*. As our readers are aware, this charming species combines tenderness with beauty, and will not stand a very low temperature. On looking over the plants, this was found to be completely done for. The outer bark was disrupted, and on removing it a singular appearance met the eye. The stem was found encased, as if in a closely fitting tube, by a film of ice, formed doubtless by the extravasated fluids of the plant!!

He further informed us that the frost afforded him an opportunity of testing remarkably the advantages of double-glazing. In the early part of last year, by a simple and ingenious process to which we may allude at some other time, he had a small span-roof house double-glazed. In a neighbouring plant-house, provided with four rows of pipes, all that could be done was just to keep it less than 6° above the temperature of his double-glazed but unheated structure.—*Irish Farmers' Gazette*.

WHAT IS THE difference between celery and salary?—The one you must bank before you can get it; the other you must get before you can bank it.

The Gardener's Magazine.

SATURDAY, MARCH 16, 1867.

DISA GRANDIFLORA IS STILL COMPARATIVELY UNKNOWN, though it was years ago described as "one of the most unusual and most glorious examples of the diversity of the floral world," and has been occasionally exhibited in the full perfection of its peerless beauty. Ask any fifty cultivators who take an interest in choice plants what it is like; and if you obtain any answer at all, it is most likely to be that "Disa grandiflora is like a gladiolus." To be entitled to such a comparison is no disgrace to any plant, but whoever knows the Disa, or has access to a good figure of it, will be inclined to quote Hamlet's figure of "Hyperion to a satyr," though in doing so the gladiolus is visited with dishonour. It is certainly a plant of rare and noble beauty, and to appreciate it does not need any such training of the eye and knowledge of its history as is the case with some plants that give immense delight to connoisseurs, and are held in light esteem by all the rest of mankind. Disa grandiflora not only deserves to be better known and generally admired, but is eminently adapted to become a popular plant, to become in fact a weed in England, and actually make a figure in our sylvan scenery. We have there already some precious gems belonging to the family of orchids; why should we not add to their number this splendid exotic orchid, which is as hardy as an *Ixia* or *Tigridia*, and would probably grow and flower luxuriantly, and increase rapidly in just such half-shaded and half-marshy habitats as *Iris fœtidissima* delights in, or would form a companion to the stately *Butomus umbellatus* on the margin of the clear winding stream and deep still lake? To be made available for the open ground, it no doubt would have to be potted up in autumn, and kept in a frame till spring; but it is probable that it would survive any of our ordinary mild winters, though it doubtless would succumb in such a winter as the last. There is one thing certain, that after years of experiment and failure in the cultivation of this splendid plant, we learn that failure is the result of attempting too much—that in fact the cultivator has unintentionally aimed at killing it, and has succeeded; but to have succeeded in keeping it, scarcely anything more was required than to leave it to take care of itself.

The Disas are terrestrial orchids, natives of the Cape of Good Hope. At various times during the present century, examples of the genus have been introduced to England, so that about fifteen species have places in the books; but none of them are known except to a few botanists, with the exception of grandiflora, and that chiefly because it stubbornly resisted all attempts to cultivate it until quite recently, when it was at last discovered that it required very little cultivation at all. In the "Hortus Kewensis" of 1813, we find two species entered—namely, *D. cornuta* and *D. spathulata*—as introduced in 1805 by George Hibbert, Esq. In Sweet's "Hortus" of 1830, we find thirteen species, headed by *D. grandiflora*, which is described as a "frame bulb, herbaceous, perennial, dying down in the winter, and shooting up afresh the following spring;" a description which is nearly, but not quite correct. It was first figured in the "Sertum Orchidaceum" from a foreign specimen, and is there recorded as having only once flowered in England. This was in 1825, when Mr. William Griffin, a collector and cultivator of bulbous plants, flowered it in his garden at South Lambeth. Again, in 1843, it flowered at Kew, and furnished the subject of a very good figure in the "Botanical Register" (t. 926), which, however, like many other good figures, rather suggested what the plant might be than represented truthfully its glorious colours and majestic form. It is customary to say that pictures of plants are exaggerations; but if we may be allowed to make a remark in passing, we will say that we have never seen the beauty of a really fine flower equalled by the happiest stroke of the most able artist. The fact is, it is impossible. The plate in the "Botanical Register" was accompanied with remarks on the treatment required by this plant, and to those remarks we are inclined to attribute the almost general failure which has attended its cultivation; for it was then proposed to treat the plant as one impatient of moisture, whereas, as an inhabitant of bogs, pools, and streams, an abundance of water is the one thing needful to its existence.

Charles Leach, Esq., of Clapham Park, is entitled to the honour—and in this case it is no questionable honour—of rescuing this No. 98, NEW SERIES.—VOL. X.

plant from the killing system by which it was attempted to cultivate it, and the oblivion to which it appeared to be destined by its apparent intractability. Great was the surprise and delight of orchidologists when in July, 1854, Mr. Leach presented to the notice of the Horticultural Society at Chiswick a fine plant, and accompanied it with some remarks on the course of treatment followed by him to ensure its flowering. Again, on the 5th of June, 1861, it was exhibited in fine condition by Mr. Leach at South Kensington, and attracted more attention than in 1854; indeed, since this last-named appearance of the plant it has been shown frequently, and we can call to mind a very fine example which was presented by Mr. Bull at the concluding show of the season last year at the Regent's Park Botanic Gardens.

The cultivation of this Disa is, as above remarked, a matter of the utmost simplicity. It will not surprise any of our readers to be told that the conditions in which it is found growing wild are to be imitated as nearly as possible, and that the cultivation consists solely in such imitation. Yet the cultivators who killed it were not altogether without information as to its habit and climatic necessities; and we must ascribe their failures to the persistent idea—an idea now a little loosened at the root—that an exotic orchid must of necessity be boiled or roasted. Sir John Herschel has reported, in connection with his astronomical studies at the Cape, that *Disa grandiflora* is an abundant inhabitant of the margins of pools of standing water on Table Mountain, that its roots are almost always immersed in water, and sometimes its leaves are bathed in dense mists that continue during the heat of the summer for one or two weeks uninterruptedly. Here it is exposed to a temperature of 96° in the summer, and of 31° in winter, giving promise as it grows at home of adaptability to the English climate. The course which Mr. Leach has found most successful is that which consists in treating it as a cool greenhouse or frame plant, needing at all times to be kept moist, and during the summer requiring to be treated as an aquatic. After flowering, the plants are set out and fully exposed to sun and air, but are protected with hand-lights, in case of frost or rain, until the end of October, when they are shifted into larger pots, the soil being rough fibrous peat, with a good proportion of silver sand; they are then placed in a cool greenhouse or frame, close to the glass, and are syringed over twice a day. They grow all the winter, the leaves lengthening and offsets coming up, and to dry them off and compel them to rest is to incur the risk of killing them. As to temperature, it is advisable to protect them from frost when grown in pots, but heat in winter is not desirable beyond that. At the end of February a little increase of heat may be allowed, and the syringing may be increased to three times a day. Such treatment with free ventilation will bring up the flower stems in May and June, and the cultivator will in due time be well rewarded. The plant dies down in winter in its native soil, but even then its roots are always moist, and it soon begins to grow again. But hitherto it has been found safest to allow no rest at all, but to keep the plant slowly growing all the winter. It has a different summer at home to ours, and that is quite enough to account for its different behaviour.

The hardness of this Disa is a matter of great importance. Long ago Mr. Smith, a gardener living at Cape Town, reported that he had seen it live unhurt through a frost that destroyed potatoes in the same garden. Our much valued, because practical, correspondent, Mr. William Chitty, who has been a successful cultivator of *Cypripedium spectabile* and *C. calceolus* in the open border, informs us that he has found the Disa to be as hardy as any British or North American orchids, and needing only to be planted at the margin of a pool or under the splash of a fountain, in a spongy peat soil, to become one of the most magnificent embellishments of the garden it is possible to plant in it. May we not hope, then, to see this stately and brilliant plant in every well furnished garden in the land in the course of a few years, especially as, when properly treated, it increases in an extraordinary manner, producing swarms of offsets, which quickly attain to a flowering condition? For the choice garden, *par excellence*, *Disa grandiflora* is indispensable, and should be found in every cool greenhouse and conservatory where variety and beauty and interest are in any degree of request. Many of our readers will understand how it is that it has occurred to us to make remarks on this plant at the present time. It has been reported that Major Trevor Clarke had proved its hardness by leaving out a plant during the past winter which was now found to be unhurt. There is just a mistake in

this report to the extent that it does not relate to any *Disa*, but to *Dyckia rariflora*, a Brazilian Bromeliad, which Major Clarke has, to his surprise, found capable of enduring the rigour of a British winter. But nevertheless the mistake (in which the GARDENER'S MAGAZINE had no share) may fairly put us in mind of the fact that this lovely *Disa* is about as hardy as *Phormium tenax*, and needs nearly the same kind of treatment, and may be regarded as a valuable acquisition both for the cool conservatory and to plant out in moist half-shady borders, or in fact to take a place in the *Gladiolus* bed to outshine them far with its splendid flowers.

THE DIRECTORY OF THE DUBLIN EXHIBITION PALACE have instituted weekly meetings, to be held on Wednesdays, for the exhibition of horticultural produce, more especially novelties, examples of cultural skill, and objects of interest, such as scarcely meet with attention at ordinary flower-shows. There are no special classes, exhibitors may send what they please, and certificates will be awarded according to merit. At the close of the season awards will be made of three prizes of £10 each, three of £5 each, and three of £3 each; but no prizes will be given to any exhibitor who shall not have obtained at least twelve certificates, and exhibited on at least six occasions. We are indebted for this information to our able contemporary the *Irish Farmer's Gazette*, in the last issue of which there is a report of the first meeting, which was held on the 6th.

THE ANNUAL MEETING OF THE UNITED HORTICULTURAL SOCIETY took place on Monday last, the President, William Marshall, Esq., in the chair. Letters from Messrs. Crute, Hibberd, and Smith, three out of four of the vice-presidents, were read, each of the writers tendering a resignation of the office. The resignations were accepted, and votes of thanks were passed in acknowledgment of the services of Mr. Crute and Mr. Hibberd. The report was remarkably brief: it stated that the society was in a prosperous state, but the committee had to regret that some differences of opinion had led to the withdrawal of two gentlemen who had contributed in an eminent degree to the society's welfare. The balance-sheet showed that a sum of £186 had been brought forward from last year, that £300 had been received from the Albert Orphan Asylum on account of the Guildhall exhibition, and that the subscriptions during the past year had amounted to £61. On the other side, the principal payments were £181 to the Benevolent Fund; advertising, £11; rent of rooms, £7 13s.; secretary's salary, £25; balance in hand, £281. Of this balance about £230 will be paid over to the Benevolent Fund. The report and balance-sheet having been adopted, the meeting proceeded to the election of officers. Mr. Harvey Brand, Mr. A. Short, and Mr. John Fraser were elected vice-presidents. The committee, with a few exceptions, were re-elected. Votes of thanks were tendered to the President, the Secretary, and the Committee. In acknowledging the compliment paid to himself, the President touched slightly upon recent events, with a view to justify the part he took in promoting the amalgamation with the Albert Orphan Asylum on the occasion of the last exhibition at Guildhall, and expressing an opinion that the recent differences ought not to have led to the withdrawal of those gentlemen who had retired from the management.

EXHIBITIONS ANNOUNCED.—The following announcements have been made subsequent to the publication of the list at page 86: *Crystal Palace*, Great Flower Show, May 25; Rose Show, June 29. *Royal Horticultural of Ireland*, Autumn Show, August 23. *York Floral Fête*, June 19th and 20th.

SPARROWS FOR AMERICA.—The *Northern Whig* states that a few days ago there left Belfast, by the Liverpool steamer, en route for New York, a rather novel consignment, namely, several hundred sparrows. Sparrows in the United States are held in high repute by the farmers, as they eat up the grubs and small snails which infest the soil.

CALLUNA ATLANTICA, the Newfoundland heath, is regarded by Professor Asa Gray as in no important respect differing from *C. vulgaris* of Britain, "so that, as yet, a second species can hardly be said to be established."

AN INTERNATIONAL BOTANICAL CONGRESS will be held by the Botanical Society of France during the time of the Great Exhibition, to which botanists of all countries will be invited. The Congress will open on the 26th of July, and will last for a month.

A tabular view of the world-distribution of British Ferns, by J. G. Baker, Esq., is the most important contribution to the March Number of the *Journal of Botany*, and we direct attention to it in this place as likely to prove of great interest to such of our readers as are at all concerned about the geographical distribution of plants.

THE "NEW FOOD."—Mr. Bateman having hit Mr. Hullett rather hard in some remarks at one of the recent fortnightly meetings of the Royal Horticultural Society, Mr. Hullett has written to say that he thought it cruel of Mr. Bateman to say what he had done at the last meeting respecting this food, leading people to imagine that the seed he sent out was only that of *Holeus saccharatus*. He sent the black seed to no one except to show the difference between it and the true thing (*Sorghum tartaricum*), which has white seed, and this he sent to over 10,000 applicants; the residue had a variety with brown seed, which is even harder than the white: both were grown by him at Waterloo last year, and both were perfectly hardy, which the other (with black seed) is not. "So much for Mr. Hullett's statement," said Mr. Bateman at the meeting on the 5th ultimo; "now for my defence. In the only two collections that I had the opportunity of examining (those sent to the Royal Horticultural Society, and to myself), in which all the three varieties (white, brown, and black) were included, not a hint was given which was the true *Simon Puro*. I was therefore obliged to find that out for myself, and my only chance was to go to the seed-shops; and at half a dozen around Covent Garden I asked for the Chinese Sugar Grass, and in every case a packet of the black seed was handed to me." Mr. Bateman therefore concluded that the black seed was the right sort, instead of which the white or the brown ought, Mr. H. now says, to have been selected. So much for the colour question; now for the question of names. As Mr. Hullett in his letter to the *Times* joined the "Chinese Sugar Grass" with *Sorghum tartaricum*, it was natural to infer, according to botanical usage, that *Sorghum tartaricum* was but another name for the Chinese Sugar Grass, a well-known plant in this country, which Mr. Hullett's *S. tartaricum* certainly was not. But if *S. tartaricum* was not the Chinese Sugar Grass, why did Mr. H. in his *Times* letter lead us to infer that it was? And if not that, what was it? Whence did he get the name (*S. tartaricum*)? Who gave it the name? He (Mr. Bateman) had spent several hours lately at the

Linnean Society's Library, and with the assistance of Mr. Kippist had tried to discover some trace of *S. tartaricum*, but all to no purpose. Neither among the *Holeuses*, nor the *Sorghums*, nor the *Andropogons*, a genus in which the former are sometimes included, was there any *tartaricum* to be found; so that if any Tartar was to be caught, Mr. Hullett must catch him himself.

With regard to the Sorghum, Mr. Bateman had collected the following information. Mr. Fortuno stated that at one time the French were very hopeful it might turn out a substitute for the sugar-cane, and tried it extensively in the south of France; but it failed. It might be useful as a fodder for cattle, but it requires a climate like that of Tein-tsin or Peking; and where rice would not grow, its place was taken by tall kinds of Sorghum, some as much as 12 or 15 feet high. It was from the long stout stubble of this grass that our cavalry horses in the late Chinese war suffered so severely. Mr. Thompson remembered it many years ago in the Society's garden, and about an acre of it was grown near Chiswick by Mr. Jessop, and who had it cut for cattle in pieces a foot long. Mr. Bateman also quoted Dr. Roxburgh as to the uses the *Holeus* or Sorghum is put to, as well as Dr. Royle, who says that the different kinds of Sorghum (called "durra" by the natives), the Great or Indian Millet, is an important branch of Indian cultivation. The species most commonly grown were *S. vulgare* and *S. bicolor*; but in another list all were classed together, viz., *S. album*, *rubens*, *nigrum*, *nigricans*, and *nigerrimum*. He had also examined the specimens in the possession of the Linnean Society, arranged by Dr. Wallieh, and which formed part of the East-Indian herbarium, and all were treated as mere varieties of the same species. These, with their black, brown, and white seeds, were then exhibited to the meeting. Mr. Bateman concluded by expressing a hope that Mr. Hullett, who seemed now to be in a communicative mood, would tell the Society, and it was the third time of asking, where *Passiflora Hullettii* (fruit of which had been pronounced superior to the pine-apple) had fruited; where and when the Durion had been fruited; and where and when the Mangosteens and Mangos, which according to his own account he cut in dozens and sold at 2s. 6d. a-piece, had been produced. Until these questions had been satisfactorily answered, he would recommend people to be cautious how they meddled with Mr. Hullett's "New Food."

CAMELLIA CULTURE.

NO. II.—THE CAMELLIA HOUSE.

ALTHOUGH the Camellia has so many admirers, it cannot be said that there are amongst them any great number of ardent cultivators—or rather perhaps I ought to say, amongst a great number who professedly admire them, there are few who provide all the conditions necessary for their successful cultivation. Therefore, however great may be their admiration of this beautiful flower, they can never see it in the state of perfection they might do, if only a portion of the expense were laid out in constructing suitable buildings for them, that is so lavishly wasted upon some other classes of plants that have only novelty to recommend them. But happily the Camellia has suffered less by depreciation in the estimation of the flower-loving public than many good old friends, as up to the present day it retains a good hold upon the affections of the public. I have no fear in predicting that we shall yet see it rising again still higher, and recovering the ground it has lost. But to do this effectually we must have steadfast admirers and skilful cultivators,—admirers who will ungrudgingly supply the means, and cultivators who will know how to use them.

But, in cultivating Camellia in the present day, the general cultivator is labouring under a disadvantage which our predecessors had not to contend with; as the present style of building our horticultural structures admits nearly double the amount of light that such buildings did in olden times. And this extra amount of light, I contend, is not favourable for Camellia culture, as every careful cultivator must have observed that they flourish much the best in a subdued light. Therefore I say, if we wish to see this plant got up to that degree of perfection it ought to be in, we must have suitable winter quarters for it, in the way of a specially designed house, where the admission of light is not so great as is secured at the present time for our fruit houses. The truth of this argument is to be tested even in these days; for wherever we see the best collection of Camellias, the houses in which they are grown date their career of usefulness far back into the beginning of the present century. It is not long since we were reminded of this in an account in these pages of an ancient and dark Camellia house, in which the trees were remarkable for size, beauty, and abundant flowering. (See page 582 of last year's issue.)

For the proper treatment of the Camellia during the two or three summer months that they may be placed out in the open air, we want a far more general provision made for their welfare than the prevailing custom sanctions, as they should not be exposed either to the parching midday summer sun, nor to the heavy storms and winds we sometimes experience. The shelter of a north wall or fence is better than none at all; but such a makeshift is not conducive to success in Camellia culture, as the drenching rains and winds are amongst their worst enemies. The best and most suitable protection for them during summer is no doubt a glass-roofed house with open ends and front on a north wall; as in such a position they would enjoy an abundance of air, and be securely protected against heavy rains; and as this roof could be temporarily shaded to reduce the amount of light, either by a canvas blind or a little lime and water, it would be just the position that they would delight in during the hot summer months. The air sur-

rounding them would be cool and moist, and they would occasion far less trouble than when standing exposed to all the powers of the elements. The next best covering for a similar structure would be felt. I have seen this used for the purpose with good effect. The only precaution necessary in using this is not to bring the front too low, or it shuts out too much light. With some such places for their summer quarters, and a suitable well-ventilated house for the other portions of the year, where the light is somewhat subdued, the cultivator has secured one of the first essentials to success.

As these remarks will appear at a very suitable season for Camellia growers, I shall give the details under separate heads, and will first direct the reader's attention to the subject of

PRUNING.

Pruning may seem a harsh word in connection with the cultivation of Camellias, but it is nevertheless essential that its application to these plants should be properly understood, as there are certain times during the life of a plant, especially with some varieties of Camellias, when the operation must be conducted with no sparing hand, as the loose straggling habits of some of them (take *Mathotiana* as an instance) cannot be kept within bounds unless the knife is used occasionally. On the other hand, there are many that will go on for years only requiring an occasional stray shoot taken away here and there. Individually, I object to the use of the knife amongst them any more than can possibly be avoided, as I have seen the almost fatal result of its indiscriminate use by some young cultivators. It is such experience that makes me cautious in recommending it, because too often the work of pruning is carried out without either skill or judgment to aid the operator; and, more often than not, the whole collection is allowed to go on for years without any attempt at pruning, until the plants become both unsightly and unmanageable, and then follows a general slaughter. The neglect of years is condensed into the work of a day, and where a few stray shoots, if they had been removed at the proper time, would now have prevented the removal of a large number, a slashing use of the knife is resorted to, to the manifest injury of the plants.

The proper season for pruning these plants is directly after flowering. As soon as any number of them are out of flower, collect them to one position in the house, and give them less water than those in flower for ten days or a fortnight. They should then be cut in, if they require it; but first give an eye to the form of the plant, and only cut away just sufficient to bring it into the desired shape. Give water sparingly for the next week, and then increase the quantity until they are shifted into larger pots. Put the whole collection through the above course until they are all set fair for shifting. But, as it is sometimes desirable to have a portion of them in advance of the others, the first lot so treated should be repotted as soon as ready, and placed in a mild moist heat to make their growth.

REPOTTING.

On the subject of potting I have some remarks to make; and first, I advise the cultivator to give liberal shifts, but not large ones, as over-potting is open to severe censure, and certainly ought not to be practised by those who have any pretensions to horticultural skill. But apart from that, if large shifts are given, a too vigorous growth is likely to result, and thereby the chances of flowering are reduced to a minimum. It requires some amount of judgment to decide in every case whether a certain plant requires shifting or not, as there are some varieties that are naturally vigorous growers, and which, so long as you afford them space to root in, will flower but sparingly. But omit to shift them for a year or two, and they will flower with a surprising freeness. And again, when the collection attains size and age, it is necessary to exercise the same caution in repotting, as very often some of them will go on for two or three years, or even more, without shifting, and still produce an annual display of flowers. When there is a prospect of their doing this, let the plant be taken out of its pot every year; let all the old drainage be carefully picked out, and some clean dry materials put in its place. I would impress upon my readers the importance of paying particular attention to this point of fresh drainage every year, when the plants are not shifted, as without some such precautions the plants will soon fall into ill-health; for without a ready means of escape, the water given them will soon render the soil soddened and sour, and by degrees the young rootlets become black and rotten, and the loss of them will not be detected by the cultivator until the sickly appearance of the plants leads to an inspection; and then very often it is found that, owing to the non-attention to the subject of drainage at the proper season, it will require a couple of years of careful culture to restore the plant again to its usual health. When it is decided that any of them should stand over for another year without a shift, if there appears to be any doubt about their going satisfactorily through the year, a mulching two inches thick of fresh-gathered sheep's dung will help them amazingly, it being a gentle stimulant and

abundantly nourishing. In every case where this is applied, the water to the plant should be given through a rose for the first month, as the water so given permeates the dressing below, and carries down with it what nutriment it contains. In similar cases sometimes, a topdressing of turfy loam and leaf-mould will afford the plant sufficient nourishment to go through until another season. But in each of these cases the cultivator must be guided entirely by the condition of the plants, and the purposes for which they are required. The above courses of treatment are given in full confidence of their utility, and with the knowledge that they can be adopted with advantage, both to the plants and the cultivator.

There is still another good reason why some judgment is necessary at this stage of their culture; for when plants have attained a suitable size for the house they are intended to decorate, and are not desired larger, they may be checked in their vigorous growth by allowing the pots to get full of roots, and supplying sufficient nourishment by topdressings or mulchings. If a perfect system of drainage is maintained, a healthy root-action may be kept up for several years without adding much to the size of the plant, and at the same time a fair share of flowers secured. With a collection of young plants, of course the treatment must be different to what has been above detailed. If it is desirable to increase their size, many of these, especially the vigorous growing ones, may have a shift into pots a size larger for several successive years. But as all are not alike supplied abundantly with roots, the observant cultivator must discriminate for himself between a weak and a strong-rooted plant, and make no attempt to increase the weak ones by giving a superabundance of pot-room, on the fallacious assumption that it will increase and strengthen them; the fact is, it would have an opposite effect. When such cases occur, with no hopes of their recovering under ordinary treatment, plunge the plant in a gentle bottom heat for some six or eight weeks. This will be found the most speedy method, and in a few months the plant will show its gratitude by its increased vigour and healthy appearance.

As a closing paragraph, I would call the reader's attention to the time, above stated, at which I recommend they should be shifted. My time is immediately after flowering; but there are one or two solitary individuals that tell us it should be deferred until late in the summer, when the flower-buds are formed. I find no fault with the authors of this plan, because no doubt, under their own treatment, it may work well. But it is so opposed to my own practice, and that of hundreds of others, that I should not advise anyone to adopt it, because I think, if we investigate the plan only lightly, we shall find that by giving the plants a fresh stimulus to action at a time when they should be gradually going to rest, and to mature and swell off their flower-buds, we are not likely either to promote the health of the plant or increase its flowering qualities. For other details as to soil, &c., I must beg the reader to wait until another number.

J. C. CLARKE.

CULTURE OF THE TUBEROSE FOR FLOWERING IN THE OPEN AIR.

Having lately read the article on the Tuberose at page 476 of the *GARDENER'S MAGAZINE* for 1866, the writer, S. H., says, "Mr. Salisbury told how to grow them in the open air—that is to say, how to flower them in borders; but I never could do it, and never met with the human creature that could!" I have felt it my duty, and I feel it to be a pleasure, to communicate on this subject, having for many years practised the flowering of this noble plant in the open border, with the most perfect success, at Beverley. I will not attempt to add to the description or the eulogy of this flower contained in the article I refer to. Let it suffice that the flower is at once one of the most elegant and most powerfully fragrant members of an elegant and fragrant family; that the plant is not hardy, and indeed is decidedly tender in constitution, and that therefore to flower it in the open border needs special preparation, and some amount of skill and care. I proceed therefore to furnish directions in accordance with the system of cultivation I have found perfectly successful.

Procure good sound bulbs, and about the first or second week in April pot them in 24-sized pots. The compost that we always used consisted of about equal parts of good yellow loam and leaf-mould with a little sand mixed with it. The pots were then placed in the back of the cucumber bed, some boards being put over the bed to keep the bottoms of the pots from the soil. We found that the heat that suited the cucumber did capitally for them. They were kept in the same place until the foliage of the cucumbers began to interfere with them. By this time (say the second week in May) they were all strong healthy plants. They were then gradually hardened off until the second or third week in June, when they were planted out in the rose-borders, where they were to bloom. The soil of those borders was rather strong loam on a bottom of clay, but they were always well dug, and a good coat of well-rotted manure dug in every winter; in fact, we always found that the soil that suited the roses suited the Tuberoses quite as

well. The only further care they required was to put a neat stick to each plant. We used common laths split in two or three pieces and painted. Care was always taken to keep the flower-stalk tied to the stick as it advanced in height; and they were never suffered to want for water in dry weather. They always commenced to flower in August, and were generally in bloom until cut down by the frost in the end of September or the beginning of October. We often had twenty blooms from a plant, and we have had as many as twenty-three. They were always very much admired by the many visitors to the gardens for their beauty as well as for their beautiful scent, which could be detected all over the gardens; and in the early morning, when we used to be mowing around them, the air was laden with their spicy fragrance. There is one caution necessary to those who would grow them, and that is to be sure and look well to the bulbs on receiving them from the seedsman. The plan that we always adopted was to take each bulb between the finger and thumb, and examine the lower part where the roots start from, as it will be often found that there is a small decayed spot there about the size of a pea. If this is not taken away, the result will be that the spot will spread, and the bulb will be useless. But if a small knife be taken, and the decayed part cut clean out and scraped, so that none of the decayed matter is left, and then let the bulb be well dried in the sun or before the fire before potting, it will be none the worse for it. The only other thing that requires care is to be sure and secure good drainage for the pots, as the bulbs are very impatient of damp, and a whole batch of bulbs may be lost by not attending to the drainage. I have no doubt that by potting some bulbs later, in places where the climate is warmer than in this flat part of Hampshire, and where the winter does not set in so early, that they may be had in bloom until nearly Christmas. Should any of the readers of the GARDENER'S MAGAZINE try this plan of growing one of the most beautifully fragrant of our summer-flowering bulbs, I trust the same success may attend them that attended the same mode of culture at Beverley.

WILLIAM MOSS, Gardener to F. Townsend, Esq.,
Shedfield Lodge, Wickham, Hants.

EXTENSION VERSUS RESTRICTION IN GRAPE-GROWING.

It is very truly remarked by many, that we live in an age of progress, and the designation "sensational," so commonly applied to the various schemes and inventions that are designed to engage the public attention, is not always inappropriate, though it is novel and is sometimes used unfairly. I am tempted to say something on what may be considered a very novel idea, that is, when compared with our usual practice as sanctioned by long established custom.

Since the appearance in the GARDENER'S MAGAZINE of Dec. 8th, 1866, of that memorable leader on the "Glory of the Vine" (p. 542), there has arisen a lively discussion as to the respective merits of the extension and the restriction systems of Grape-growing. Mr. Cannell of the Fuchsia Nursery, Woolwich, made a stir by announcing in his Catalogue, published about six weeks ago, "a hint worth £100.;" this hint being to the effect that vines would be more healthy if allowed more room, and that if severe pruning above ground were practised, there ought also to be severe pruning of the roots. As an observer and practitioner of many years' standing in Vine-culture, I venture to offer a few observations on this subject:—

Some of the features of the practice recommended are not new to many of the gardening profession, as, for example, that of allowing the branches of one vine to cover the space usually occupied by several distinct plants; for by such a system, as is well known, they produce excellent crops of superior fruit. I believe that if the inquiry were extended, we might be enabled to cite numerous examples confirming the fact throughout the country.

Now it is quite understood by the growers of specimen plants for exhibition that, in order to secure a plant favourable in every way for the purpose, it is best, if possible, to choose it from among a number of the same age. It may appear a strange analogy when I say, as with the animal creation, so with plants—some will, though subject to precisely the same treatment, take the precedence of the rest, both in robust and rapid growth. Nurserymen, and other large growers who propagate their own collections of various plants, have in their choice an exceptional advantage compared with the general community of gardeners. Again, it is not uncommon to observe, where several vines are planted in the same prepared border and subjected to the same treatment, some will outstrip the others, not only in the present but in the future. Now comes the question, shall we depart from the practice almost universally adopted—that of planting a single vine to each rafter—or have recourse to the Editor's suggestion made three months ago, and now backed up by Mr. Cannell's advice—that of allowing one vine to suffice for the whole house, so that its branches may have every encouragement for freedom of growth?

For young gardeners, or those whose means are limited, to commit themselves to such a plan would, I anticipate, in many instances prove a fatal mistake. Departure from established rules by way of experiment is not advisable where it is likely to interfere with our expected returns, for with the majority of cultivators more experiment is out of the question. I have always maintained that gardeners, beyond every other class of artisans, were greatly indebted to local influences for extraordinary success in some of the branches of gardening; so that previous to recommending for general adoption any scheme that may have proved beneficial elsewhere, we should well consider the means that have aided or retarded our own success, and whether partly they may not be attributed, independent of skill, to a combination of circumstances. It is a well-known fact that very many of our most eminent Grape-growers in this country are

favoured by natural resources available within the vicinity of their practice. As one of many instances confirming my assertion, I would just refer to a well-known grower who supplies the London market with grapes—Mr. Rochford, of Page Green, Tottenham: this gentleman has a very extensive range of glass entirely confined to their culture. The same are of marked perfection both in growth and fruitfulness. The soil which constitutes the greater portion of the vine-borders is obtained from the spot on which the houses are erected. There is an advantage of the greatest importance to the cultivator. Now on that very plot of land occupied by Mr. Rochford there are two distinct strata of soil, and their effects on vegetation are just the opposite of each other. An example of it was forcibly illustrated by two plantations of black currants in the said grounds; the one growing luxuriantly, while the other presented the reverse of it. We will attempt to discuss some of the reasons advanced by Mr. Cannell, as an argument in furtherance of his teachings.

It may be in the recollection of my readers, that in a paper written by me on the failure of Peach and other fruit trees under glass, in the GARDENER'S MAGAZINE of last year (p. 491), that I refer to the failure of the breaking of the eyes of the early forced vines under the care of Mr. Davis, the gardener at Roehampton Park, and his subsequent treatment of them by the cutting of the rods back to the lowest eyes, and the remarkable growth they afterwards made. If Mr. Cannell would treat himself with a visit to Roehampton Park at the present season, and witness the result as now exhibited, I am persuaded that his opinion afterwards as to the non-use of the knife would undergo a revision.

In my previous paper on vines, as inserted in the magazine, I have always maintained that if there is a healthy root-action, then the well-doing of the vine is within the compass of the skill of the gardener; but the very act of allowing the shoots or branches to have full scope for their extension will not, I am certain, counteract or check the evils complained of, and which are attributed to the use of the knife. It is the neglect of external remedies which is too often productive of the evils common to grape-growing, although I am willing to admit that in too many cases the knife is only one amongst many of the influences for good or evil. Failure is the result of indifferent root-action. The want of colour in the grapes is sometimes caused by allowing them to become thickly infested with red spider, which cripples the energies of the vine, and renders the wood weaker and weaker, and thus it is unable to develop sufficient substance for fulfilling the requirements of fruitfulness in the year ensuing; so that both branches and berries become indifferent in size, and the consequence is that, if the vigour of the vine is not quickly renewed, then a failure in the crop must follow.

Further, I must affirm that mildew is not the result of sharp pruning, nor always the want of healthy action at the roots; but the presence of a stagnated moist atmosphere, in the absence of enough heated air to balance the temperature during the prevalence of dull cold weather. If, as Mr. Cannell supposes we do not—by the planting of one vine to each rafter—ensure that vigorous reciprocal action between the roots and the branches which ought to exist, surely we can accomplish it by occasionally cutting the rods back to the lowest eye, and thus reproduce new canes. I am justified in safely recommending the practice to others by what I have witnessed in the case of the vines alluded to at Roehampton Park.

JOHN F. McELROY.

HEREFORDSHIRE ORCHARDS.

The planting, cultivation, and general management of orchards has long been well understood. As early as 1656, Dr. Beale, in a very valuable treatise, entitled "Herefordshire Orchards a Pattern for all England," entered into full particulars respecting it and other matters of local agricultural interest. From this source we learn that the favourite system of forming young orchards was then, as it is now, to plant them in pasture land intended to be broken up and cultivated as hop-yards. The trees are thus well protected during their early growth, which is much promoted by the manuring and cultivation of the soil; and as soon as they become of a size to injure the hops, the land is usually again laid down to pasture. Thus an orchard is established at a comparatively small outlay. Both apple and pear trees occasionally grow to a great size. I have an apple tree from which, according to the evidence of the late proprietor of the estate, as many as 94 bushels, of 10 gallons per bushel, were once gathered by him; and near the vicarage at Holm Lacy, and within a short distance of the railway station, there is a remarkable pear tree, now extending over nearly half an acre of land, from the fruit of which it is stated, on good authority, that in one year 1600 gallons of perry was made, while tradition speaks of the extraordinary produce of 2,500 gallons at the time of its full vigour. On this, however, it is only right to observe that what is called "a tree" consists of a succession of trees, caused by the lower boughs having fallen to the ground and taken root; thus the parent tree, which died long ago, became surrounded by a group of trees, each one in itself of considerable size, and forming in the aggregate apparently one tree only of great lateral dimensions. I have measured one of these scions, and its girth at 4 feet from the ground was 10 feet 10 inches. The best old kinds of cider fruits are the Red Streak, Moyle, Foxwhelp, Skyrme's, Kernel, Hagloe Crab, Royal Wilding, red and yellow Styre, Cowarne, Red and Kingstone Black; but they are so difficult to propagate, and such uncertain bearers, that latterly several new sorts have been imported from Normandy, and have grown into favour, not only on account of their kindly growth, but their prolific yield. The sorts principally grown are the Strawberry, Huntsham, and Comey Norman, and the yellow, red, white, and black Norman; but the preference should most probably be awarded to the Strawberry, the yellow, and the Huntsham varieties.—*Duckham on the Farming of Herefordshire.*

MR. HULLETT'S WONDERS.—We have not met with any one who has seen Mr. Hullett's Passion Flowers and Mangosteens, or the wonderful "annual fruit" from Siam, which has seeds as big as a child's head; nor have we seen any of these things ourselves, nor have we been able to find any authentic account of them in any work of authority. We suppose the *Sorghum Tartaricum*, seeds of which were offered through the medium of the *Times*, to be identical with the sugar-cane grass, *Holcus saccharatus*, described and figured in the *Floral World* of 1858, p. 128. If it should not prove to be identical with this plant, we nevertheless feel fully persuaded that no one will ever eat a loaf of bread made from the seeds of this grass ripened in England. It may prove to be an ornamental grass, and perhaps of some value as fodder, but as a cereal adapted for this climate, it is worthy, we believe, of cultivation only by a madman.—*Floral World.*

MESSRS. F. AND A. SMITH'S NURSERY,

PARK ROAD WEST, DULWICH.

This extensive nursery is chiefly occupied with tender plants, and consists almost wholly of glass. Alterations are in progress in the construction of a drive to connect it with some land the Messrs. Smith have lately added to extend their frontiers, and on the margins of this drive there will be a display of coniferous trees; but nevertheless it is not a tree or shrub nursery, but a place covered with glass, and the houses all crowded with subjects of considerable value. I had strolled about some time before I saw a human creature, and I had taken note of the crowded state of the houses and the healthy appearance of the plants, and in particular of the miles and miles of hard-wooded plants in low pits and large span-roofed houses, when I halted at last in the midst of a mass of primulas, all so fresh and bright and good, that I was at once satisfied that the trip to Dulwich was well made for a curiosity hunter. At that moment one of the principals came along, shutting up the house, bang, bang, and I caught his eye as he caught mine, and in about twenty-five seconds we were tearing away in a discussion about primulas in general and these in particular. Now I must remark that it was to see what was going on in the primula way that I went to Dulwich. I have been full of curiosity about the primulas there; for it happens that I have noted every stage of improvement of this flower for about twenty years past, and so different are they now to what they were then—the large, rosy, lilac flowers being then the best—that I almost expect to see them transformed into roses, but nevertheless fervently hope they will never be anything else than primulas. It is a grave question with cultivators as to whose seed is the best, and at this time of year there are many debates in plant-houses as to the respective merits of the various strains that are grown for the market. And speaking of market reminds me of a market grower who paid a good price for seed at a house that bears a good name, and when the plants were in flower in January, and primulas were realizing a good price at Covent Garden, he could not pick out a dozen really good ones from amongst about five thousand. Estimate them at sixpence each all round—good primulas realize more than that early in the year—and this man's loss may soon be calculated. The case is not so bad when a gentleman's gardener discovers that he has been growing rubbish, but the case is bad nevertheless; and therefore it is no wonder that houses famous for this or that particular seed can generally sell as much as they can produce of it, and indeed during the present season many sorts of seed, such as hollyhocks, balsams, and even lettuces and endives, are so scarce that not a tenth part of the customary demand can be met, owing to the bad seed-time of 1866. For these and other considerations I felt particularly interested in the Dulwich primulas, and I am bound to say that I saw as fine a lot set aside for seeding as I have ever seen during multitudinous travels and experiences. The right way of ripening seed is to keep the several strains separate, and, if possible, to have them in bloom at different times. If seeds of good whites are required, it is not advisable to have reds in bloom in the same house with them at the same time, because of the many crosses that are sure to occur. But, above all, the matter of greatest importance is never to allow an inferior plant to remain in the place an hour after it has proved itself to be inferior, for the pollen will find its way to good flowers, and tell most injuriously on their progeny. Messrs. Smith, and all other practised seed-growers, know all about this of course, and act accordingly; but many gardeners not accustomed to seed-saving desire sometimes to grow a pinch of seed, and these remarks, suggested by the capital system I found in action at this nursery, may be of service to some of our readers.

But the primulas I went to see are double ones. They put me in mind of some of Messrs. Windebank and Kingsbury's superb examples, and I suppose there are not to be found in cultivation two finer varieties than two that I found here. One is white, the other is carmine-rose colour. The name of the first is *Queen of England*. The flowers of this are extra large, elegantly fringed, very double, the petals laid upon one another in a most exact yet luxurious manner. The colour is at first pure white, but this gradually changes to delicate blush-pink, so that the plant is covered with flowers in several shades of the refined and delicate colours. When I say "covered," I mean covered; for I counted on one plant in a 48-size pot thirty-six flowers full open, and fresh, and there were about twenty-five more to come. Reckoning for many that had been clipped out, for it is late in the season to see primulas, I suppose each of these plants had produced one hundred flowers. The name of the other is *Carminata plena*. It is a most queenly flower, of large size, and has six layers of petals laid one above the other in a regular imbrication, all of them elegantly notched; the colour lively carmine-rose, or rosy carmine pink, peculiarly fresh and pleasing. In addition to these there are many other beautiful varieties, but I made note of only one which happened to be amongst the singles, the flower of which is splashed and barred with rose on a white ground.

The double primulas are easy things to handle when you have them, but about the hardest things in the world to get. Talk about the rapid multiplication of soft-wooded plants, here is a case for the boastful propagator to manufacture a few thousands from one plant, and to do it in time short enough to pay, and well enough to ensure the good opinion of the purchasers. Of course, they are shut up after flowering, and the stools usually break up freely, and to make and strike the cuttings is easy work; yet there is such a difference in the ways of doing things, that now and then we meet with double plants that grow as freely as seedlings; but commonly there is a great difference, and many gardeners give up the doubles because of the trouble they experience in growing them, and their poverty of appearance at last. I counted the flowers on the old plants of the two double varieties, which are not the originals, but the first generation from the originals, in order that I might be able to say if the system followed here in making double plants is good; and I leave it to the practical to say if 100 flowers on a plant in a 48-size is good or otherwise; but I ought to add that the plants had leaves as well as flowers, and leaves such as we do not often see in cases where there is much flower in small pots. There was a great batch of the fern-loaved primula in the same house, making a very beautiful bed, more leaves than flowers; it is, in fact, not so free in flowering as the common form of *P. prænites*, but its fine character, and very graceful and characteristic outlines, entitle it to the highest consideration among spring flowers.

Having seen and said all that could be seen and said in the primula houses, I soon found my way to the hard-wooded department. Camellias appear to be done here as extensively as at Chandler's years ago. I went through furlongs of potted stocks that were in preparation for working, and of nice young plants growing freely in dark houses, and of good store plants almost advanced enough to be setting their blooms for next year.

So again with azaleas; there are thousands of them in all shapes and sizes, and a large stock too of all Messrs. Smith's own seedling azaleas, on which it is our business to report annually as they make their appearance at flower-shows. There are some nice things amongst the newest of these, such, for example, as *Amethyst*, rosy purple, a very showy variety for decoration; *White Perfection*, the best single white out; *Excelsior*, which I remember well as it appeared at the Royal Botanic, rosy purple, finely spotted, a thorough show-flower; *Humboldt*, superbly formed, the colour rosy salmon; and *Oracle*, equal in form to *Stolla* or *Vesuvius*; in fact, it cannot be surpassed in this respect; the colour is rosy pink with superb spots. This, besides being a first-class show variety, has as good a habit as any azalea known. Heaths, Epacrises, Hedaronas, and all the rest of the good hard-wooded plants, abound.

But what I saw in big houses of these was nothing to the stock in low pits. There are twenty of these pits in a row; each pit is 100 feet long and 10 feet wide, the paths between are 6 feet wide; they form a regular range, and are all heated with two rows of 2-inch pipe, the pipes being all connected with a main that runs through the centre of each pit. The main is at first a 6-inch bore, then it contracts to 5-inch, next to 4-inch. Every pit is separately connected, and at a touch of the finger any one of the twenty pits, whether the one nearest the boiler or the one farthest away, can be made either a cold pit, a warm pit, or a forcing pit; perhaps even a cooking dépôt, for there is abundant command of heat. As a rule they are kept rather cool, and the pipes are there for safety rather than for growing. What first struck me was, not the extent and order of the range, for that I am used to, but the perfect health, the brilliant appearance, the abundance, the variety of heaths, and epacrises in those pits. To pick out species and varieties is out of the question now; it is sufficient to know that there is scarcely a heath or epacris worth growing that may not be found here to the tune of a hundred or two, and of some sorts there are thousands. After such a winter, such a fearful time for houses three hundred or more feet from the boiler, as the most distant of these are, the assurance that not a leaf of anything had been hurt in any of these pits (in which, by the way, are many things more tender than heaths and epacrises), I went up to see the boiler; and I found in a well built stoker's two of Weeks's upright tubular boilers, one at work, the other quiet, but ready in case of an accident to do its duty. This is a very satisfactory example of the one-boiler system; the amount of pipe heated is about three miles, and the main and all the branches are nearly on a dead level.

The inspection of these things led to the unfolding of a tale; for at the upper end of this range of pits, and in fact close over the boiler that feeds them, are three neat span roofed houses which share with the pits the same flow and return. Here one of the members of the firm has carried out a new system of glazing without putty, which has not only stood the test of time and proved sound and good during stormy and frosty weather, but is elegant, admits more light than any other method, and is quite as simple in the end as putty, especially for repairs. Suppose the sash-bars to be cut as usual; but the rebate has a groove which serves as a gutter to carry condensed moisture from the roof to the eaves outside, and the squares are placed edge to edge without laps, and are fixed by means of headed screws, which just press upon them at the sides and no more. The lowest square has to some extent to bear the downward pressure of all that are above it, and it is fixed by a bit of lead or zinc bent to the shape of a letter S, which catches it at the lowest edge. For houses in which a flood of light is required this system is admirable. There is no drip, no cracking during frost, and to replace a broken square is a simple matter of releasing the screws that press it in its place and inserting another. There is no felt, no list, no soft stuff or padding anywhere; the glass is held in fact just as a workman would fix it for a temporary purpose with brads, but it is done neatly, completely, and wears as well or better than putty.

This is a bad time of year to judge Tricolor Geraniums, but at any time the difference between Mrs. Pollock and Tom Thumb may be seen; and at this time it is no hard matter to see in such varieties as *Souvenir de Sir Joseph Paxton*, *Sunshine*, *Refulgens*, *Jetty Lacy*, *Louisa Smith*, *Defiance*, *Beauty of Surrey*, and a few others in the extensive and splendid collection here, characters that place them in the front rank, and establish them in the best esteem of the best judges. The Tricolor house at Wellington Road is a spectacle, and is well managed for effect. Here no effect is attempted, it is sheer work; and if an impression is made on the visitor, it must be by the merits of individual things, not by any *tout ensemble*. It is proper to this report, therefore, to say that Messrs. F. and A. Smith have made tremendous strides in the breeding of tricolors, and in due time the public will have a chance of making selections from the varieties that are now being propagated for sale. *Amulet* has a finely coloured leaf, the edge deep yellow, the zone black and red, the flowers scarlet, the habit bold, and the whole carriage noble and effective. *Beauty of Surrey* has a yellow margin, a red and brown zone, brilliant in colouring, and distinct from all else in the same line. *Eclipse* is perfectly dazzling in the brilliancy of the zone colours, the prominent tint being vermilion-red. *Glory of Dulwich* is remarkably fine in colouring, the margin yellow, the zone a mixture of black with several shades of red. *Jetty Lacy* has a yellow margin, and a zone compounded of chestnut, red, and black; it is a good grower, and eminently effective. All those named above are fine; but there is no time or space to dwell upon their beauties, and I select as superb beyond all ordinary things in the way of Tricolors *Souvenir de Sir Joseph Paxton*, which has a sharp, narrow, gold-yellow margin; a zone of crimson breaking into bars of black, the older leaves changing to purplish carmine, so that the brightness of its youth is the presage of the subdued and ripened lustre of its age; how well named, therefore, after the veteran who so early gave tokens of genius, and so late in life displayed the full strength of a great mind, and a pure taste and deep appreciation of beauty! There are many more good ones in the hatch—one in particular, with leaf extravagantly convex, and very charmingly edged with creamy variegation, the disc being dull green. I missed the name of this, but it must be hunted up, for the leafage is of the most distinct and pleasing character.

In the soft-wooded collections, Cinerarias are an important feature. Messrs. Smith have bestowed much pains upon what may be called the tricolor section. In these there is the usual dark disc, the usual coloured margin, shading to another colour at the base of every petal (flore), so as to form a sharp inner ring of colour distinct from the colour of the ordinary broad ring, and within that a ring of white. *Flower of the Day* is one of the best of these. The margin is plum colour, shading to a sharp ring of magenta; next within this is a ring of white, and the centre is

nearly black. *Blue Beard* is exquisite in colouring: the margin is deep blue, the boundary to that is a sharp ring of crimson, then comes the ring of white, and the disc is dark and convex like a button. *Conspicua* is not a tricolor, but its crimson edge is heavy and rich, and the flower is one of the best in form that has been seen. Certainly these cinerarias of Messrs. F. and A. Smith are a tremendous argument against my doctrine, that in a packet of average good seeds you have all the varieties. Cinerarias were going down but a few years since, now they are reviving; in fact, they must revive when flowers of such superb quality, and so altogether new in character, are brought forward.

Pelargoniums, Verbenas, and all the rest of the popular flowers, are admirably represented; indeed, of pelargoniums of all kinds there are thousands—some destined for market, some for show, some for bedding, all for the delight of mankind, and I hope for the profit of their producers. Amongst the early flowering kinds, the following merit the special attention of people who indulge in forcing: *Etna*, scarlet and black, very showy and good, and decidedly early. *Flamingo*, well made, crimson and black, decidedly early. *Herald*, a second early, very striking, the colour vermilion, with black spots and white throat. *Premier*, rose and crimson, fine, and early. *Attila*, rich crimson, ruby and rose, superbly formed, and very showy. *Elegantissima*, most valuable for any purpose, especially for decoration or cut flowers, white throat with mauvy veins, top petals mauve, with large deep purple blotch. *Refulgens*, ruby and crimson black, very neat habit, remarkably attractive. *Snowdrop*, the best forcing white I have yet seen: *Alba multiflora*, with all its good qualities, is nothing to it. I might have made a note-book as long as the pipes in the twenty pits amongst the pelargoniums, but I marked down only such few as struck me by their superior style and thorough distinctness.

I made a special search after Roses, and found two or three houses crowded with *Manettis*. The new sorts appeared alone to have away, and own roots were out of the question; indeed, Messrs. F. and A. Smith assured me that they had no time to fidfad with things that were slow and uncertain, and the quickness and certainty of *Manetti* put own roots out of their heads. I saw nothing at all to make notes on amongst the roses, for of course none were in flower. But I forget; there was a batch of *Isabella Sprunt*, all neat plants, in 54-size, carrying half a dozen long pointed yellow buds each. It is evidently a wiry grower, and the buds wanted another week to bring them open. From what little I saw of it, I should say that it is a mistake, that the variety is as bad as its name, and will not be known after a year or two. Getting among miscellaneous things, I noticed a big batch of *Chrysanthemum Sensation*, which is to be in great demand this spring, in consequence of the GARDENER'S MAGAZINE reports on bedding last year. All the *Alternantheras* are here too, and the *Teleiantheras* too, but it looks as if these should be raised from seed; it is quite hard work to do them from cuttings, though they are being done that way, and there will be plenty to supply the gardeners in the month of May. In the stoves are many interesting subjects, one of the most interesting being a plant of *Ficus Cooperi* in fruit. The fruit is as large as a plum, the colour green, with brown stripes. In the houses devoted to mixtures of greenhouse plants, I noticed a good batch of *Acacia eriocarpa*, the most useful of all the species in cultivation. It is easily propagated from the soft tops of the shoots, and is well adapted to be made a market plant, and as it is tolerably hardy it might do for the plunging system, if kept back by the coolest possible treatment. The appearance of a batch of *Boronia serrulata* pleased me much; rarely is it seen in condition equal to the plants here. It is kept growing all the winter, and this method makes a great difference in its favour. *Kennedy microphylla* is a superb basket plant, the growth thick and elegant, and plentifully dotted over with scarlet flowers. A thousand other subjects worthy of mention must be passed over; but it will be proper to remark in conclusion that the collections of plants grown under glass are extensive in a marked degree: the camellias, for example, comprise 200 varieties, the geraniums about 600, the azaleas and heaths innumerable, and so on throughout all the departments: hence it is a capital rendezvous for collectors to exchange notes and make purchases, and there is room enough amongst the pits for extemporized congresses to settle offhand all the moot-points left moot by the formal congress of 1866.

THE VERBENA.

This stands next to the geranium in the scale of relative popularity amongst bedding plants, and is justly entitled to the favour it enjoys. It is an admirable subject for exhibition, and affords both brilliancy and variety to light up less attractive subjects; and in the garden it affords, in addition to colours and tints eminently attractive, some few that we cannot obtain from any other flower. I shall endeavour in a short practical Paper to set forth the principal points in the cultivation of the Verbena, for all the several purposes for which it is used; and as this is the season for propagating, we will take that subject first.

CUTTINGS.—The best plants for all purposes are those grown from cuttings made in February and March. The plants from which cuttings are to be taken must be placed in a temperature of 60° a few weeks in advance of the time at which it is desired to commence striking cuttings. Where there is a great demand, this of course must be early, as the young plants when potted off will furnish a crop of cuttings, so as to prolong considerably the season of propagating, which may be said to last from the 1st of February to the 1st of May, after which date it is very little use to strike any until the end of July or the beginning of August. For home use, the best time to strike cuttings is the second week in March, and the best cuttings are young shoots two inches long, taken off with a small knife at the distance of one eye from the main stem. In case I am not understood, let me say that a shoot is selected that has grown about two inches, and it is cut off in such a way as to leave at least one leaf with its accompanying eye remaining. From this base of the young shoot a new shoot will presently appear, which also may be cut when large enough. When the utmost possible quantity must be raised from a few plants, young shoots an inch long will answer, and it is better to take them off with a small knife, working it against the thumb, than to remove them by means of the thumb-nail, as is the practice of some. If this plan is not fast enough, the cuttings may be split lengthwise; but that is a very nice operation, and I suppose the man capable of performing it needs no advice of mine.

As fast as the cuttings are made, they must be dibbed into pans or boxes filled with silver sand. Nothing to equal shallow boxes, in fact nothing like wood everywhere about a propagating house, and old wood is

better than new. To insert the cuttings is an easy enough task: if there is enough clear stem to fix them in the sand, you need not take any leaves off, but now and then one of the lowest leaves must be removed; at all events, there must be no leaves half buried in the sand, for they will quickly rot, and cause the cuttings to rot with them. To strike Verbenas in this way is one of the easiest operations in horticultural practice. Yet many amateurs and single-handed gardeners find it a difficult task. I will endeavour to make the path of success free from thorns. In the first place, when you begin to work, be quick about it. If the cuttings lay about and get flabby, they will be a long time recovering, and will be difficult to handle. Two inches depth of sand is quite enough if the pans or boxes stand on a damp bed; and every part of a propagating house should be damp; it is half the battle. The sand should be damp when the cuttings are put in; they may be put as thick as they will stand, and when the box or pan is full, give a gentle sprinkle with water; put the box on the tank, dung-bed, or shelf over flue or pipes, wherever indeed there is a heat of 60° to 70°, and a considerable degree of atmospheric moisture. A dry place is death to such little soft cuttings as these. If you must strike them in a dry heat, put bell-glasses over, or have a little glass-frame of some sort to shut them up in. In case of sunshine, lay sheets of paper over the cuttings, but do not, if you can help it, shut them up in the dark, or in a close steam. The advantages of a propagating-house are manifold; there is a steady heat, a genial humidity; walls, paths, and shelves all give off, owing to their moist condition, genial exhalations that tend in a marked degree to promote the free rooting of cuttings, and yet there is plenty of light and a large body of air, so that the young stuff, though forced, is healthy from the first. Gardeners who have not such an advantage must make the best of bell-glasses and flues, dung-heat and common frames, and steal a few batches of bedding plants by putting pans of cuttings into cucumber and melon pits. I shall say nothing about the possibility of the cuttings damping-off, except that it is impossible if there is heat enough, and they are not absurdly drenched with water. Keep them quite moist, and in ten days every one will be rooted.

It is best to pot them singly into thumbs as soon as they begin to push roots, so that from the first they may have food, which the sand will not afford them. Make your mixture of any nice light rich stuff, with a good proportion of silver sand. If you wish to do the most extremely proper thing, prepare a mixture as follows: clean loam containing much fibre, two parts; gritty fibrous peat, one part; manure rotted to powder, one part; silver sand, one part. Let this be well chopped up and passed through a half-inch riddle. Set aside the coarse and the fine stuff in two heaps under cover, and in potting use the fine only for the thumb-pots, but at the next shift to 60-size, use the lumpy stuff at the bottoms of the pots. There are all sorts of ways of potting, but they are all alike in principle. If I had to pot a few thousand verbenas from cutting-boxes, as I have many a time, I might say hundreds of times, in my early days, I should set a boy to work to sift a heap of coal-ashes, and provide me with a few bushels of cinders, or fragments of clinker of the size of hazel-nuts, and from that to a walnut. I should sit down comfortably at the bench, with a heap of stuff to the right, a heap of cinders and sieve to the left, pots before me in the middle, cuttings close to hand. I should take a pot, throw into it a cinder, then a handful of stuff, and give the pot a tap; then deftly place the cutting with its two or three white roots spread on the mould, and cover it with a little more stuff, and quickly place my two thumbs on the soil to press it gently, and then whip it into the sieve. I should require a boy to feed me with pots, mould, plants, and cinders, and to carry away the sieve as fast as I filled it, giving me another at the same time, that I might not be a moment without it. Of course the little plants would go to a warm place, and I should prefer for them exactly such conditions as I have described for the cuttings, a damp bed to stand them on, and a heat of 60° to 70° to make them grow.

But again, I think of the man who must grow these things by thousands, and who must turn them out as fast as they are potted. Now we want a pit with a bed of equal parts half-rotted dung, and half-rotted hops, made rather extra wet, six inches deep on a wooden floor, under which there should be at least one 4-inch flow and return. Thus we should get a moist heat of 70°, and they would grow at a pace. As to air, they will want none until they are getting strong, and the weather is genial; but stopping must be attended to, and if fine plants are wanted, they must be shifted to 60-size as soon as they have filled the thumbs with roots. The first stop must be done when they have made a fair start in growth after being first potted. Delicately nip out the point of the plant, and it will presently put out side-shoots, which are the first foundations of a good plant. It is too much the rule to keep them in thumbs till bedding-out time, and they soon run into bloom in consequence. Then when planted out they have to recover themselves from the starvation they suffered from being too long in thumbs, and they grow vigorously for a long time before they flower. In nursery practice this can hardly be avoided, for purchasers will not pay for the shift to 60-size. But I advise every amateur who wishes for a fine display, commencing early and lasting long, to grow the plants generously, and never to allow them to become pot-bound. In fact, for a fine effect I would stop a second time, just before shifting to 60's, then again after they have got well hold of the soil in the 60's; again when they have made a free growth, and if time allowed, and it happened to be a backward season, I would shift to 48-size, and have them strong and well hardened off before planting out. But very few will do this, indeed very few can do it; and in 60-size fine thumping plants may be obtained without starving. As the season advances, they will of course do well in cold pits, and will want plenty of air; indeed, "pushing" according to the plans recommended is only needed in the earlier stages of their growth. There is yet another mode of procedure admirably adapted for the private garden, where plants are grown for use and not for sale. It is that which I have frequently recommended for the calcicolaria, as one step towards curing that plant of its fatal faculty of suddenly disappearing from the spots it was intended to embellish. It is that of planting them out from the cutting-pans into beds made up in frames a foot deep, consisting of light rich soil. These beds should only be made up a day or two before being required, as they will then be warm, especially if shut up during sunshine, and the plants will make a nice start. After planting, water them in with tepid water, and give no air for several days, shading from hot sun by means of canvas or mat, and of course taking care they are not roasted. After about four days give a little air, by tilting the light with a bit of stick to make a blink of two inches or so. Sprinkle them daily about noon, and at once shut close. Their growth will astonish you (unless you are used to such ways of doing things), and at bedding time you will have plants of the sort which the Magazine usually denominates "thumpers."

Of course, as they get stronger you will give more air, &c. I have now detailed the thorough practice of propagating as I understand it after years of practice. What I have said applies to almost every sort of plant propagated from cuttings at this time of year, and really it applies to the practice of an amateur, with only one plant-house or only a frame or two, as much as to the wholesale routine I have been accustomed to, for the same precautions are needed in every case, and every one can adopt them in a way to suit his own circumstances.

VERBENAS IN BEDS.—The situation of the Verbena-bed should be open and sunny. The verberna never blooms freely in a shaded position or in a poor, hungry, dry soil. Any good loam that will grow a cabbage will do admirably, and the same bed will do for verbenas again and again for any number of years, if dug over in November and left rough, and dug again in March, and refreshed with some good rotten manure. It is because people will not treat their beds in this way that they become "verbena sick," and they wonder how it is their verbenas will not bloom. If soil is prepared for verberna-beds, let it consist of mellow loam, with a fifth part of its bulk of rotten dung, and the same of leaf-mould or peat. I once had a heap of silt that was dredged up from the bottom of a river. It consisted of sharp grit, small shells, mellow mud, and the remains of aquatic plants in patches of black humus. This was heaped up in a part of the grounds near the river that was much frequented, and though we "pitched into it" might and main, summer came before we could get it all wheeled away to the kitchen garden, and there was still a small mountain left. I thought of covering it with succulents or gourds; but work pressed hard, and when the bedding was finished at the end of May, I took all the surplus verbenas of all sorts and sizes, and stuck them in all over the mound "anyhow," and left them. Fortunately mild weather with showers followed, and presently they began to grow like the bean-stalk in the story; and I confess, with all the joy proper to the man who makes a discovery, that they bloomed as I never saw verbenas bloom before or since. It was wonderful; the little mountain was like an earth-cast consisting of rubies, topazes, emeralds, garnets, with some bits of Mount Vesuvius all afire to fill up amongst them. It was all chance and accident, but I had coolness enough to take a lot of praise for my skill. However, putting aside all vanity, I take comfort that I know now what is the perfection of a soil for verbenas, and I fancy a few other things would have grown in that heap.

The distances at which verbenas are planted must depend on the habit of the variety. To take Purple King as a standard, I have been accustomed to plant it at 15 inches every way; in very rich soil and in a warm moist climate, I should put it at 18 inches, and in a poor soil and cold dry climate (as in some parts of the East of England) at 12 inches. Fixed rules are not wanted; a treatise which suits every case suits none, and the wise man carries with him the key to the paradox. Use your judgment; learn if possible what is the growing strength of the variety you are planting, and if you cannot learn it, try to make it out for yourself, by the relative size of the leaves and thickness of the shoots, for these are pretty safe criteria.

Plant them so that the shoots they have will tell best for effect. For example, in the case of a bed or several rows in a ribbon, let the first row lay towards the edge, and be full 15 inches from it; let the second row lay towards the first, and so on; this will make the most of them for covering the ground. When any shoots are promising to go beyond the line allowed, pinch the point out, and guide and train so as to cover the surface of the bed regularly. But I must tell you here something worth knowing. You may practise pinching with benefit from the time of planting to correct legginess, and promote an even distribution of the growth; but it is not well to practise pegging until there is a general show of bloom all over the bed, for *pegging checks the growth*, and the freer the growth at first the better the bloom at last. Some sorts never want pegging at all, and a perfect bedding verberna should spread itself as from a centre, and make a circular tuft all over leaves and flowers. The most perfect I know of in respect of habit is Maonetti and its varieties; they literally make mats of vegetation, but then they are not showy, and so they come short of perfection. In regulating the growth, the shoots may be allowed to cross one another, if there is anywhere a space to be filled; but where they overcrowd each other, it will be well to cut a few clean out. When a shoot has done flowering and is pushing side-shoots, it may be really in the way, and its removal therefore may be advisable. If so, cut it out; if not, nip away the old truss to prevent the growth of seeds, and let the side-shoots come on in their own way, and they will soon begin to flower. Here again fixed rules are out of the question. Use your judgment, and be thankful that the most accomplished adviser cannot supersede the intelligence and forethought of the individual cultivator, but must after all leave him free to use his brains, if he has any, or go to the bad if he has none.

To finish up this part of the subject, my advice to all bedding people is, that cuttings of all the kinds intended to be kept be taken in the last week of July or the first week of August. These will strike without the aid of artificial heat if put in frames or under hand-glasses, and if carefully kept through the winter will furnish cuttings in March, and will also be useful for planting out. And it may be proper also to add that old plants make good beds if geraniums or calceolarias are planted in front of them; but if we have to look down directly on them they are not always nice, as they generally show six inches or so of naked woody stem, and lack the lively vigour of young plants.

VERBENAS FOR EXHIBITION.—You don't want directions for obtaining the plants, but the hint may be acceptable that cuttings struck early are the best, and that the most plump and healthy-looking plants should be selected. The most shrubby habits are desirable, but generally, and properly, the cultivator thinks most of well-made flowers, fine trusses, and brilliant colours, three qualities of the very first importance for exhibition purposes. The young plants must be stopped as soon as rooted, and the after-treatment should be directed towards the formation of a handsome plant. They are usually flowered in 8-inch pots, the points of the shoots being constantly pinched out until within about six weeks of the date of the show, from which time all the shoots are allowed to run into flower. Early flowering should never be allowed; learn this by heart. The compost for growing them should be such as is already recommended, but without any sifting. The best place for them after the end of April (or earlier in a forward season) is the cold frame, and from the middle of May the lights should be off in good weather, night and day, but in case of cold weather put them on at night, and while heavy rains last put them on during the day also. Tie and peg them out as taste may dictate, making a nice plant, like a head of hair with curls all round uniformly. In case of mildew, dust

them with flowers of sulphur; but very rarely does this plague come if the growing is liberal from the first, as here recommended.

SEEDLINGS.—If you have the seed, sow it now, and start it in a heat of 60° to 70°. Treat the seedlings as advised for cuttings, potting them singly when they have three or four leaves a-piece, and by no means allow them to become drawn and weak with crowding. Plant out or flower in pots as may be most convenient. As a large proportion of them are sure to prove worthless, it is best to plant them all out rather thick, and in the end of July or early in August take cuttings of the best, and flower a pair of each under glass in pots the next season. In some rare cases a few may be named in the seed-bed, and their trusses exhibited. Generally they make finer flowers the second year, that is from spring cuttings taken from the original plants. Hybridizing is not difficult to perform, though rather a niggling job. Very few of the new varieties are the result of actual manipulation, though the raisers generally make a very wise appearance with their assertions about having crossed this, that, and t'other.

PROPERTIES.—Exhibition flowers should be large and flat, and in large trusses of a hemispherical form. The petals should be stout and velvety, the edges smooth and freely overlapping, so as to make a thick substantial flower, with a regular circular outline. The colouring should be dense, rich, or pure of its kind, well laid on with no blurring intermixtures or indecisive elouds. If there is an eye, it should be distinct, circular, and a clear white, lemon, or gold colour; a green eye is objectionable, and a coloured but dirty eye equally so. A sharply defined and perfectly circular eye in a flower otherwise good is a great charm. Many of the newer exhibition kinds are finely got up in the edges and the eye. Stiff foot-stalks and a healthy habit are essential. As for bedding varieties, colour and habit decide their values; it matters not whether the flowers be smooth or rough, if they are of a suitable colour and are plentifully produced, with sufficient substance and stamina to hold their own during bad weather.

NOTES ON A FEW VERBENAS OF SPECIAL MERIT.

Antonia.—Claret crimson shading to black, violet eye; a very fine variety for pots or beds.

Attraction.—Large, and finely formed, deep maroon crimson shading to black; a grand flower, and fine for pots or beds.

Alexandra.—White, mottled, and striped with purple; fine.

Annie is still the best of all the striped varieties, though dozens of them have been sent out to compete with it.

Ariosto improved, though an old variety, is still the best of its colour, fine puce.

Beauty of England.—The finest white for show.

Blue Shade.—A superb blue for beds.

Brunette.—Crimson, with auricula-like lemon eye; not large, but finely finished.

Cleopatra.—Bright rose, large white eye.

Coleshill.—A grand scarlet, with lemon eye.

Charles Perry.—Blush shading to crimson at the base of the petals, white eye; a curious, very distinct, and beautiful flower.

Delicata.—Delicate pink, lemon eye; most beautiful.

Gladitor.—Large pips and large trusses, carmine deepening to crimson, white eye; fine.

Gem.—Scarlet, with white eye; fine for exhibition.

John Keynes.—A most beautiful exhibition variety, scarlet, with white eye.

Junius.—The most distinct verberna known, having a fiery orange colour; in quality second-rate, but a very fair bedder.

King of Verbenas.—Dark lavender, fine auricula eye.

King of Scarlets.—A superb show flower; scarlet, with large round white eye.

L'Avenir de Ballant.—A fine old variety; rosy carmine.

Leah.—Finely formed, smooth and stout; colour clear pink, fine white eye; beds well.

Lalia.—A good grower, trussing well, bold and handsome; dark lilac, with violet-crimson centre.

Lady Jane Ellis.—White, with small green eye surrounded with a rosy ring.

Madame Cointet Aine.—A most beautiful variety for pot culture; colour white, with carmine eye.

Madame Hermann Stenger.—Scarlet striped with white; quite novel and beautiful.

Mauve Queen.—Fine form; mauve marbled with white.

Miranda.—Large and good form, blush with carmine eye; fine for pots and beds.

Mrs. Dean.—White, with scarlet centre; distinct and pretty.

Mrs. Elphinstone.—Well known and long established, and not yet beaten in its colour, which is a warm puce-rose.

Merry Maid.—Large, showy, carmine-rose shading to purple, fine trusses; quite a show-flower.

Napoleon Bossi.—White, striped lilac; a first-rate bedder, and greatly superior to Striata.

Nemesis.—This old favourite is still considered indispensable to a collection; it is a well-formed showy self, the colour scarlet with pink shade.

Polly Perkins.—A first-rate bedder; the colour rich magenta.

Queen of England.—A remarkable style of flower; the form good, the colour pure salmon, with flame-red centre.

Renaudet.—A splendid verberna, scarcely at all known; the form equal to any, the colour rich velvety crimson shading to black.

Rosy Circle.—Puce-rose, lemon eye; first-rate bedder.

Royalty.—Carmine, light centre; beats Lord Raglan both for exhibition and beds.

Shakespeare.—A very large, stout, and smooth scarlet-shaded crimson; a grand show-flower, scarcely at all known.

Startler.—In the way of Lord Raglan, and a better bedder.

Spark.—Crimson with primrose eye; sometimes better than Lady Binning.

Triomphe de Massifs.—One of the grandest show-flowers; the form good, and the trusses immense; colour cobalt blue with indigo shade, white eye. A good truss of this may be likened to a piece of gorgeous jewelry, and in the buttonhole of a Prince Esterhazy would pass for a thousand pounds worth of precious stones.

White Queen.—A fine white, of the best form and excellent habit of growth, not given to mildew, and behaves well during bad weather; first-rate for pots and beds.

William Dean.—First-rate in pip and truss; colour deep rich purple, with white eye.

Warrior.—A fine old favourite, quite first-rate still; colour rosy-pink, with white eye.

The foregoing forty-three were selected last summer from amongst some two hundred varieties, all growing in the same bed, as especially worthy of remark for their fine characters, good habits, and other qualities briefly stated in the descriptions given. I shall now offer a few selections.

A SELECTION OF FIFTY VARIETIES FOR POT CULTURE.

Alexandra	Foxhunter	Mme. Hermann Stenger
Annie	Géant des Batailles	Marie Rendatler
Antonia	Gladiator	Mauve Queen
Ariosto Improved	John Keynes	Minerva
Attraction	King Charming	Mrs. Dean
Beauty of England	King of Lilacs	Mrs. Elphinstone
Black Diamond	King of Scarlets	Nemesis
Black Prince	King of Verbenas	Ocean Pearl
Blanche of Castile	Lady Jane Ellis	Pallavicini di Brescia
Brunette	La Grande Boule de	Peep o' Day
Charles Perry	Neige	Queen of England
Charles Turner	Leah	Shakespeare
Cherry Ripe	Lælia	Triomphe de Massifs
Cleopatra	L'Avenir de Ballant	Warrior
Delicata	Lord Craven	White Queen
Duke of Cambridge	Lord Leigh	William Dean
Edward Barnes	Madame Cointet Aine	Wonderful.

A SELECTION FOR BEDS.

White.—Blanche of Castile, La Grande Boule de Neige, White Queen.

Rose and Pink.—Long Looked For, Laura, Mrs. Elphinstone, Ariosto Improved, Cicely, Leah.

Crimson.—Attraction, Crimson King, Fire Brigade (these two are much alike; the first is best for good soils and situations, the second for bad positions, especially if poor and dry), Brilliant de Vaisse.

Scarlet.—Lord Clifden, Mrs. Woodroffe, Startler.

Yellow.—Junius, fiery orange, Orange Perfection, orange pink, lemon eye.

Lilac.—King of the Lilacs, Napoleon Rossi, Lælia, Lady Leigh.

Blue.—Celestial Blue, Blue Shade, Azurea superba, Madlle. Marie Rendatler.

Purple.—Ocean Pearl, Purple King.

VENOSA SECTION.—These are usually classed as the "Velvet cushion" series, a very happy descriptive designation. They are the result of various crosses effected between *Verbena Venosa* and various garden varieties. The growth is dwarf and compact, forming close tufts of very neat leafage, above which the flowers are borne in neat hemispherical trusses. They are admirably adapted for front lines of ribbons, and in fact for any purpose where a close growth and abundance of colour are required. The best of this series are Scarlet Cushion, brilliant scarlet, Velvet Cushion, magenta colour, Silver Lake, dark rose, Beauty of the Glen, lavender blue, Golden Ray, dark rose.

Verbena Venosa has become deservedly popular of late years as a bedder, especially to mix with variegated leaved plants, the bright rosy colour of its flowers having a very cheerful effect. It is quite hardy, and may be left in the ground all the winter, in the same way as any other hardy herbaceous plant.

VERBENA MELINDRES.—This Beunos Ayres species has become deservedly popular, after being for many years treated with contempt, and almost lost to cultivation. It produces a profusion of glittering scarlet flowers, and has been advantageously used to mix with variegated leaved plants in beds. It is generally considered a difficult plant to keep through the winter, but there is a simple method that never fails of success, and for which preparation must be made at this time of year. Let us suppose the cultivator has a few old plants from which at the present time to obtain cuttings. These cuttings should be taken from shoots that have grown three inches, leaving, as before described, one eye and leaf at the base of each shoot to start again. The cuttings strike readily in a heat of 60°, and when rooted are potted into small pots in light soil. At bedding-out time a certain number of these are set aside for next year's supply: the remainder are planted where they are to flower, and there they are allowed to perish. Those set aside are shifted into 48-sized pots, and kept in cold frames all the summer, or on open beds of coal-ashes. In autumn they are housed, and kept airy and cool through the winter; and from these cuttings are taken for a fresh supply both of bedding and store plants. It is the attempt to keep through the winter plants lifted from the beds that is to be avoided; if kept in pots from the first, *Verbena melindres* is as easy a subject to winter as any in cultivation.

USES OF VERBENAS.—The uses of verbenas in beds need not be dwelt upon, for it is principally for this purpose the plant is cultivated. But they are also of great service to decorate the greenhouse and conservatory in summer and autumn; though the gardener who uses them largely for that purpose will never be thought much of amongst lovers of good plants, for to use bedders indoors largely indicates poverty of knowledge and limitation of resources. However, this is a use to which they may be put. To make the best of verbenas for this purpose, strong plants should be potted into 6-inch pots during April, May, and June: the soil to be good fuchsia compost. As everybody is not familiar with the requirements of the fuchsia, here is a recipe for compost for potted verbenas: mellow turfy loam four parts, well rotted stable dung, rather fat, passed through a sieve, two parts, good leaf-mould two parts, sharp sand one part. In place of leaf-mould thoroughly rotted hops may be used, or the most fibrous part of tough spongy peat chopped rather small. Mix the whole well together, break all lumps, but do not sift it. Keep them shut rather close in a frame for a few days after potting; then gradually expose them to the weather, keep them regularly watered, and train them into neat forms, to make dwarf round-headed plants of them. If many weak side-shoots are produced, pinch them out. When the trusses begin to form, remove the plants to a cool, light, airy greenhouse. Now begin to aid them with weak liquid manure twice a week, keep them clean, and wait for your reward. An immense number of cut flowers may be obtained from a collection grown in this way, and as there will always be a few left after the bedding is finished, it is advisable to turn them to account in this way. In selecting plants for potting, give the preference to those that have been stopped, and have made some nice shoots close down to the collar. Another most legitimate use for the verbenas is in the furnishing of suspended baskets. Of course the lanky growers are the best for this purpose, but almost any except the stiff upright kinds will answer. Fire Brigade, though a very

dwarf grower, answers well in baskets, on account of its tendency to spread, so that it soon forms a fringe of leaves and flowers on the side of a basket. Another and a very effectual method of displaying verbenas, and one well suited to a grower of seedlings who wishes always to plant out a few of the best, and perhaps has no care for ordinary bedding, is to plant them on the face of a sunny bank or rockery, intermixed with graceful plants, the verbenas being in detached patches, with no particular order as to colours, and the patches separated some two or three feet from each other, so as to make blotches of colour rather than masses.

WINTERING VERBENAS.—The plan proposed above for wintering *V. melindres* will answer admirably for the whole collection of bedding kinds. If it is not convenient to keep plants in pots all the summer, take cuttings from the beds the first week in August, and put four cuttings in a 48-sized pot, in a rather poor sandy mixture, the pot well drained. Sbut up these pots in a frame rather close for a fortnight, by which time they will be rooted, and must have air. Harden them gradually, and keep them in the sun out of doors till as far into October as will be safe, taking care not to allow them to be frosted or soddened with cold rains. Then house them in a light airy house, and keep them near the glass, or put them in a pit. They will go through the winter well if kept safe from frost, and in fact will bear 6° to 8° of frost unhurt, if at the time rather dry, and if struck early in August. If cuttings are made later than the first week of August, a gentle bottom-heat must be used to persuade them to root quickly, and in the case of a cold bad time when the cuttings are made early, or if only hard, woody shoots can be obtained, heat must be resorted to. But it is far better to get them well rooted before the 15th of August in cold frames; they are so much hardier for the winter. Give plenty of air all the winter, and never allow them to go dry unless you apprehend frost, in which case withhold water for fear it should become necessary to mat them up.

VERBENA DISEASE.—The black spot and the poor condition of verbenas at this time of year are two results of defective nutrition. The cure for what is known as "Verbena Disease," and which usually appears during February and March, and is accompanied with patches of fungus, which a good lens will resolve the black patches into,—the cure for this is as simple as the cure for hunger, which can be applied wherever there is food. Find in a propagating house or stove, wherever there is plenty of light, and a rather moist heat of 60° to 70°, a broad wooden shelf, nail a three-inch edge to this shelf, and then spread on it three inches of rotten dung. Place the verbenas on this bed, keep the bed moist, and in a week from the commencement of the treatment there will be signs of new growth in the points of all the shoots. The disease will disappear, and you will obtain five times as many cuttings, and all healthy too, as by any other method. Of course, as they will root through, they must not be moved at all from the time they are placed on the bed till they are worn out, and have to be thrown away. If not convenient to treat them in this way, let the heat be 70°, the pots on a damp shelf, and weak manure-water to be given twice a week.

MILDEW AND VERMIN.—Whenever mildew appears, dust with flowers of sulphur. If insects of any kind, fumigate with tobacco. If anything is the matter with them the nature of which you cannot make out, syringe with a solution of soft-soap, at the rate of half a pound to a gallon of hot water, using the mixture when tepid. Be prompt at all times in checking insects or mildew. When taking cuttings, if there are any indications of fly or spider on the plants, as in a hot dry summer there may be, dip all the cuttings into the soft-soap solution before inserting them in the pots. Lastly, never allow a lot of verbenas to lay about in a starving state in thumb-pots, for they become diseased and smothered with vermin, and do mischief that will spread far and wide, and last long; they may, in fact, contaminate all the verbenas in the place, and secure a strong outbreak of verbenas disease the next spring. It would take time and space that we cannot spare to prove this, and all I will say is, when you have finished planting, do something with the surplus stock at once, or destroy it.

I regret that this paper appears later in the season than was designed. Some time ago I requested one of our most able and experienced cultivators to treat upon the *Verbena*, and he commenced his work in earnest, but was immediately taken ill, and was unable to proceed. I have therefore at the last moment taken up the subject, regretting much that my excellent friend was not permitted both to do better for our readers than I have, and also to save me the trouble, for time just now is more than precious.

S. H.

VITALITY OF SEEDS.—In a paper addressed to the Academy of Sciences, M. Pouchet, the celebrated physiologist of Rouen, gives an account of some experiments of his on the vitality of the seeds of the *Medicago Americana*, a sort of clover. A vast quantity of wool is received at Elbœuf from Brazil; but it is in a very dirty state, and contains, amongst other impurities, the seeds of various plants. M. Pouchet was told by several credible witnesses that the seeds mixed up with this wool would strike root and grow up into plants even after undergoing a four hours' ebullition during the various operations of dyeing. This was a startling assertion, it being admitted on all hands by physiologists, from Spallanzani downwards, that the vitality of seeds is utterly destroyed in boiling water. M. Pouchet resolved to verify the truth of this alleged fact, and accordingly boiled some of these seeds for exactly four hours without any interruption. After this operation, the seeds of the *Medicago* were found to be enormously swollen; the water had become mucilaginous, and it was with no great faith in the success of his experiment that our author put these disorganised seeds into flower-pots containing earth utterly free from any seeds of the same kind. Nevertheless, in the course of from ten to twenty days, several plants sprang up; and this experiment was repeated more than twenty times with equal success. After minutely examining all the circumstances, M. Pouchet at length found that among a large number of seeds in a state of utter disorganisation, there were yet a few that had successfully resisted the action of boiling water. They had, indeed, borne the temperature of 100° Centigr. for the space of four hours, but their outer tegument had proved water-tight by some unexplained circumstance. Our author immediately concluded that such must also be the case with other seeds, and he accordingly tried with wheat, barley, millet, &c., but without success; for the present the seeds of the *Medicago* are the only instance of this wonderful vitality.

BREAD WITHOUT YEAST.—To every half-quartern of flour add one teaspoonful of carbonate of soda and half a teaspoonful of salt; mix all together; then to the water, sufficient to make a dough, add half a teaspoonful of tartaric acid; put into the oven at once. This makes beautiful sweet bread.

Calendar.

WORK FOR WEEK COMMENCING MARCH 16.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—Get manure on to the plots that are to be sown or planted this month and next, and dig the ground over deeply, and leave rough. Level down the ridges of ground prepared last month, so as to be ready to sow and plant as soon as weather permits. Plant the main crop of potatoes where the ground is well drained at once, but on damp soils wait till next month. It is not safe to manure for potatoes, but charred rubbish, old mortar, and other dry materials may be used to lighten the soil and nourish the crop. For main crops use a plot that was well manured last year; for early sorts that are to come up before the autumn rains set in, manure may be dug into the trenches. Potatoes are best planted in trenches, and covered loosely with soil; dibbling is apt to cause rotting by the holes getting filled with water. Horseradish may be planted in any spare corner, but the ground should be dug deeply, and the roots will come finer if the subsoil is well manured. The crowns should be planted fifteen inches deep, and six inches apart every way, and the holes filled up with fine coal-ashes, or the sets put in as the trenching proceeds. Any part of the root will do as well as the crowns, if cut into inch pieces. Mark out onion beds, and let the soil be liberally manured. Get ready for all successional summer crops, so as to have the ground firm and well sweetened in time to receive them. Make sowings this week of Broccoli, Carrot, Cress, Peas, Onions, Lettuce, and a small breadth of Cabbage. Keep the hoe in use to destroy weeds. Earth up beans and peas as required. Plant out early-sown cauliflowers as soon as the weather is mild and promising, but not while the wind holds in the east.

TURNIPS sown now will require a soil that has been well manured and pulverized, so as to secure a quick growth of handsome roots for use in a small state. There are many sorts adapted for sowing now, such as *Early Stone*, *Early Dutch*, *Snowball*, and *Early Strap-leaved*.

BEANS must be resown again if there is any likelihood of a demand for them late in the season. For quantity, the best is *Johnson's Wonderful*, but for quality *Green Windsor* cannot be surpassed.

BROCCOLI.—Succession plants must be provided in considerable breadths by sowing at once. It is much better to sow in pans and boxes, and give them the shelter of a frame, than to sow in the open ground; but in sheltered places seed-beds on warm borders will do very well now. We have never had such fine broccolis as from plants brought on with care in the earlier stages of growth; they get less clubbed, less attacked by bot and weevil, and when put out in well-manured ground are handsome plants to begin with, and the result justifies a recasting of the adage so as to make it "handsome does as handsome is."

REMAINDERS OF CROPS are oftentimes allowed to become nuisances. We see heaps of cabbage-stumps rotting on the ground, and emitting poisonous odours, or still occupying ground for which they pay no rent, or at best give a few sprouts which in the end will be of far less value than the rows of spinach and early saladings that might have been obtained from the same spots. The most satisfactory way to deal with old stumps of cabbage, broccolis, &c., is to chop them up, throw them into a trench two feet deep, sprinkle fresh lime upon them, and cover them over. By this treatment they return to the soil very much of what they took out of it, and the lime makes a quiet end of the vermin that have identified themselves with the ancient cabbages.

CARROTS to be sown for the main crop if the ground is dry and fine. If it is wet, or consists of hard clods, wait a bit; another week may improve it much, especially if east winds blow freely. All fine seeds that are destitute of albumen, as carrot, parsnip, lettuce, &c.—in other words, all seeds that have little substance in them, require more care in sowing than seeds that may be described as fat, or that have a decidedly visible bulk, such as peas, beans, cabbage, &c. These flimsy seeds should be sown when the ground is tolerably dry, and the surface well broken, so that the seeds can be covered securely, yet lightly; if buried deep, or let fall anyhow amongst rough clods, only a few will germinate, and the crop will be patchy, or, as the farmers call it, "a bad plant."

PEAS to be sown for main crops; and to balance the remarks made under the head "carrots," we will here say that peas and beans should be sown four inches deep. They will not push through quite so soon as those that are sown just covered with a scratch of earth; but when hot weather comes, they will stand it better than those sown shallow, and give far larger crops.

PEAS in a forward state in districts exposed to the full blast of north and east winds, require a little protection, or half their life will be blown out of them. First earth them up well, this will protect the lower part of the stems; next put sticks to them of sufficient height and strength to carry the crop; and, lastly, stick short lengths of evergreen branches along the rows, or on the windward side only. Peas so treated now will three weeks hence be a full week forwarder, to say nothing of their superior freshness and health, than those that have to fight it out, though the same sorts on the same ground, and sown the same time. In the end it may make ten days' difference in the date of the first gathering; if it makes only two or three days, the gain of days will more than pay for the extra labour.

POTATOES peeping through the ground must be covered with a drawing over them by the hoe of fine soil; or if there is a good store of burnt earth, burnt brushwood, or other alkaline and carbonaceous material of a rough kind, turn it to account to cover the young haulm lightly. This will foster the tender leaf, and screen off light frosts, and the washings down of alkalis by the rain will greatly improve the crop.

RHUBARB that has stood long in the same place may be taken up, divided, and planted in fresh soil. This is essential to the production of large, early, handsome stalks. The soil for the new plantation should be a deep loam, abundantly manured. If it is half marshy, it scarcely matters, for rhubarb seldom suffers in winter through being in a damp soil, and in summer it always grows the better for it. If the cultivator takes any pride in the growing of fine rhubarb, he will not take a single stalk from the new plantation the first year. If otherwise, a few stalks may be thinned out when the plants have begun to grow freely, which of course will be rather late in the season, but they must be very moderately taxed for the use of the kitchen.

SALSIFY is the root which has been sometimes described as the "vegetable oyster;" when properly cooked it is delicious, and the pity is that it

is so little known. To grow it well, trench a piece of sandy loam, putting a good body of manure at the bottom of each trench, so as to make a manure bed two feet below the surface. Sow the seed in drills fifteen inches apart; cover lightly; thin to nine inches apart; keep clean with the hoe, and wait till November. Then take up the roots, and they will be large, long, and handsome. Trench the ground again, dress it with a good surface coat of charred refuse, and it will make the best onion-bed in the parish.

SCORZONERA to be grown the same way as salsify, but the distances to be eighteen inches and twelve inches. If either of these are grown on ground not improved by a subsoil of manure, the distances for salsify may be twelve and six inches, and for scorzonera fifteen and nine inches.

WINTER GREENS of all kinds to be sown in very small breadths, so as to secure a few early supplies of the several sorts.

Flower Garden.

HYACINTHS in frames must have plenty of air to keep the spikes short, and to retard them. As the bloom will soon be over, and as flowers of many kinds are now abundant, it will be well to keep a few hyacinths for decorative purposes to as late a period as possible. Those that have not been taken out of frames are mostly full of colour, and will be in perfection in another week or so. If kept cool and airy, and near the glass, they will last longer and look better than if put into a warm house. Give hyacinths in pots plenty of water; it makes an immense difference in the character of the spike and the leaves that surround it.

CALCEOLARIAS for hedging to be freely exposed to the air, but to be covered at night in case of frost.

CLIMBERS FOR THE GARDEN to be grown liberally, so as to have them a good size by the time they are planted out. It is miserable to see elaborate trelliswork, and the supporters of pavilions, &c., naked until about the middle of July, as they very frequently are, owing to the microscopic size of the soft-wooded climbers that are planted in May to cover them. Where the plants exist already, now is the time to shift them on into larger pots; and if they do not exist, there must be no time lost in obtaining seeds, cuttings, or plants. The following are useful plants for trellises, poles, walls, and to sprawl over hanks, &c., in the flower garden: *Abrota viridiflora*, *Boussingaultia baselloides*, *Calampelis scaber* (*Ecremocarpus*), *Calystegia oculata*, *C. pubescens flore pleno*, *C. pubescens simplex*, *Cobaea scandens*, *C. scandens foliis variegatis* (very beautiful), *Dioscorea batatas*, *Lophospermum Hendersoni*, *L. spectabile*, *L. scandens*, *L. grandiflorum*, *Maurandya alba*, *M. Barclayana*, *M. kermesina*, *Mikania scandens* (*German Ivy*), *Passiflora cœrulea*, *Pterospermum acerifolium*, *Fylogine suavis*, *Rhodochiton volubile*, *Thaladiantha dubia*, *Thunbergia* (various colours), *Tropæolum canariense*, *tuberosum*, and of sorts, *Vinca elegantissima*.

POLYANTHUS.—Seeds to be sown in pans of light rich soil; not to be put in heat, and the seeds never to get dry. If it gets dry for one day after it is sown, it will probably never germinate.

GRASS TURF requires careful dressing now to ensure a good sward during the coming summer. The turf should be well rolled with a heavy roller; any patchy or mangy places should be returned, and all alterations, such as cutting new beds, turfing where beds have been, &c., completed speedily. If the grass is poor throughout, and it is not intended to renew it, spread over the whole surface a thin sprinkling of nitrate of soda. Again in the middle of April give another sprinkle, and again at the end of May another. The result will be a stronger growth without coarseness, new grass in many places which are now nearly bare, and a green turf in July and August, when except for this care it might be worn-out door-mat.

BALSAMS for bedding out to be sown this week. These need not have such high culture as those now coming on for early bloom in pots, as short, sturdy, slow-growing plants are required. Balsams must always have a rich light soil, suffer no check, and be well supplied with water.

Greenhouse and Conservatory.

SUCCULENTS are growing, many of them flowering or about to flower, and all want the cultivator's help. Such as are topping over the sides of the pots, and want more room, should be repotted. In doing this, remove some of the old soil from the roots, but do not strip the roots bare: put them into pots a size larger than they were in before, and use a mixture of mellow loam, nodules of chalk of the size of walnuts, sharp sand or sifted sweepings of gravel walks, and thoroughly decayed cow-dung, equal parts of each all through. In place of chalk, broken brick or old mortar may be used. They must have plenty of sun, and they may have plenty of water now.

HERBACEOUS CALCEOLARIAS to be shifted into larger pots, and have a mild bottom-heat to assist them in taking hold of the new soil. The mixture to consist of loamy turf, leaf-mould, peat, and cow-dung, all in a sweet and decayed condition. A moist atmosphere will greatly contribute to the production of fine trusses, and also to prevent the spread of greenfly.

HARD-WOODED PLANTS growing freely will be much benefited by careful stopping of leading shoots, both to make the heads more compact and uniform, and also to produce a heavier mass of bloom when the season for flowering comes round again. Ericas are growing freely, and must have more root-room if the plants are large compared with the size of the pots they are in.

LILIUM AURATUM must now be kept near the light, and have regular watering. If allowed to get dry, a good bloom cannot be expected. So also with *Lilium lancifolium*, the shoots ought now to be three or four inches long, and the roots are greedy of moisture. Any *Lilium* not yet potted up for the season must be attended to immediately, as they will grow now, whether cared for or not, and it is not kind to allow them to feed on their own vitals.

PELARGONIUMS are now pushing into flower in all cases where they have been some time without a shift. To cure this bad propensity, stop first and shift afterwards. Those shifted a month ago will now want stopping, or flower trusses are sure to appear. The only way to deal with them is to nip out the points of all the shoots, and cut back a few joints any shoots that are pushing out beyond the general circumference. Keep them rather close after the operation, to encourage the pushing of the lower buds. Gauntlets and other early kinds now in full bloom must have a genial temperature, very judicious ventilation, and liberal supplies of water. All the early blooming kinds are tender, and do no good at this time of year unless assisted with fire-heat. Those coming on for early summer bloom to have all the sun possible, and to be shut up early.

BEDDING PLANTS have not made much growth of late. Keep the stock warm, and give little air. We shall soon have bright weather, when they may be more freely ventilated, to harden the wood and check their growth.

Let nothing remain in the cutting pans after forming roots, as every day beyond the proper time is a day wasted to the injury of the plants.

DAHLIAS at work will require to be potted, and those not set to work should be laid over a tank, or placed on dung-heat at once, to get strong plants. The Dahlia grower is, however, reminded that the gain in time by early propagating is sometimes a loss in the end, and is at least a matter of much more importance to trade than to private growers.

GREENHOUSE PLANTS are now in active growth, and require more than usual care. Green-fly and all other enemies will abound, and if not kept in check irreparable mischief will ensue. See at night that there is water in the house to warm and soften for next day's use. Use the syringe among Fuchsias, Acacias, and other subjects that are now growing freely. Be careful in giving air that there is no chill, and regulate watering and ventilating by the weather. As soon as the weather gets warm and settled, pass every potted plant through your hands, to shift those that need it, top-dress those not shifted, and to prune, train, and propagate as occasion may require.

Stove and Orchid House.

STOVE AND ORCHID HOUSE.—During the fine weather with which we are usually favoured at this time of the year, a kindly heat must be kept up, for there is at such times plenty of light to stimulate vegetation; but owing to the prevalence of east winds, the houses soon cool down after sunset unless the heating is well managed. Shut up early, say at 80° to 85°, and allow a fall to 60°, or even lower, during the night. Stove-plants, recently cut back, and now breaking nicely, to be shaken out, and repotted in smaller pots than they were in before, and be immediately plunged into bottom-heat. In case of being in doubt about the proper soil for any stove-plant, use equal parts turfy loam, peat, and leaf-mould, and add sharp sand enough to make the whole friable and porous. But this general advice is not to stand in the way of the little trouble needful to discover what is the best mixture for any particular plant.

Forcing Pit.

CHERRIES in the forcing house are showing a good crop this season. Do not be in haste to thin the crop, as during the process of stoning it will probably thin itself. But take into consideration the subject of thinning nevertheless, and be ready to thin if the trees appear to be laden with more than they can fairly bring to maturity. Keep the leaves and roots rather dry while stoning is in progress, but take care not to cripple the trees by over-ventilation while the wind blows keenly from the east.

PEACHES.—The remarka under the head of "Cherries" may be considered to apply to this department. The stoning process is slow, and to the young cultivator rather trying. During this period the temperature must be tolerably uniform, ranging from 55° at night to 70° by day as the extremes either way; the roots to be kept rather dry, and as much air given as possible without causing a chill. When the fruit are as large as cherry-stones, thinning should commence, but must not be all done at once. Luxuriant shoots to be stopped back, and a sharp look-out kept now for black-fly on the under sides of the leaves at the points of the shoots. "Apbis Wash" will settle them expeditiously.

STRAWBERRIES under glass require frequent and liberal supplies of water at the roots, and sprinkling over the leaves. They must also have something stronger than water at the roots occasionally while swelling their fruit; but manure-water should be withheld a few days before gathering. See former notices under this head. Strawberry in the open ground may now be heavily mulched, if not done already. Let there be no deep digging near them, and see that the plants are firm in the ground. Plantations made now will give a moderate crop.

MELONS begin to require considerable attention to set the blooms; train the vine, thin out the superabundant growth, and ventilate cautiously. The more fully developed leaves are better if evenly distributed, so as to have a fair share of light; leaves that are overlapped may be removed, and no side-shoots should be allowed to push which are likely to crowd the vine and rob bearing laterals. But the other extreme must be avoided; thin plants will never produce fine fruits, and none should be allowed to bear until they have acquired a robustness of character. The smaller kinds of melons may be very successfully grown in pots, and if well managed the fruit so produced is invariably handsome and finely flavoured.

PINES.—Plants recently shifted and scarcely yet growing require much care, especially to shade them during sudden bursts of hot sunshine, and beware of giving them too much water while they are making new roots. When the heat can be sustained without-trouble in pits properly constructed, there is no plan so satisfactory as planting them out, or plunging the pots, and allowing the roots to run out into the bed.

VINES that have begun to swell their fruit will be much benefitted by an abundance of atmospheric moisture, if the heat is kept steady. The thermometer should not go below 65° by night, nor above 80° on the brightest days; but 75° may be considered a good day average. In houses where the vines are coming into bloom, there must be less moisture. As the atmosphere is just now in a damp condition, a little extra fire may be used, as stagnant moisture is most destructive to pollen. As grapes begin to show colour, more air must be given. Prevent crowding by stopping laterals, or removing them altogether where not wanted. One thing must always be kept in mind, and that is, that every bunch of grapes should be shaded by its own leaves.

CUCUMBERS in bearing to be kept in good health by very careful ventilation and a steady heat. During dull weather, water very sparingly, so as to allow of keeping them rather close. Those coming into bloom to be regulated carefully, and the laterals stopped above the second joint. Thin the crop in time, if fine fruits are required; but where produce is more important than size and beauty, they may be allowed to bear all that set, and they will be sooner over to make room for succession plants. A brisk heat in the frames may be encouraged now by linings; but vermin will abound unless a sharp look-out is kept to fumigate when needed.

SOMETHING ABOUT TREES.

Every lover of rural life enjoys a few days "outing," when time and business will allow, away in the country amongst the woods and parks, to admire the grand old trees,—ah! and in old churchyards as well,—to gaze on the noble elms, the giant oaks, and the beautiful sombre yews, with the graceful willow hanging over the tombstones and sweeping the ground,

With branches twisted like a maze,
Just to break the vulgar gaze.

About two years since I had a rare treat in this way, and extended my journey to Scotland, and "did" the country, to use a tourist phrase, between Melrose and Edinburgh. I was delighted with the old trees and old castles, and in fact with all and everything. I saw the remains of some venerable old ash-trees (the largest, I think, I ever saw anywhere) in Bowden kirkyard, just the other side of the Eldon hills, by Melrose. These trees appear to have been planted all around the yard, but the storms of ages have destroyed all their tops. There some of them lay in wild confusion all around the trunks, whilst many of the trunks themselves are hollowed out to the depth of three or more feet. I was told that the minister in the heat of summer would mount up in the hollow of one of these old trees, and deliver his sermon. And very sensible of him too, I say; for the church is small, and I am sure both himself and the congregation would be more at ease in the open air, and the hollow tree would make an excellent pulpit. But, be that as it may, the sight of the old trees, and the idea of what they were in their prime, occupied my thoughts most, for never did I see so many patriarchs so close together in one spot before; but now, like the dead around them, they are fast going to decay—

For as man, so trees, as time does fly,
Together, in the dust shall lie.

I saw some fine old trees as well at Dryburgh Abbey, the burial-place of Sir Walter Scott, also along the banks of the Tweed, and the rugged glen leading from St. Boswell's; and again, going further north towards Edinburgh, the country is beautifully wooded, along the banks of the Esk especially, from Penicuik to Roslin and Hawthornden. Through the kindness of Mr. Ramsey, gardener to Sir George Clerk, Bart., I was allowed to accompany him through a part of the beautiful grounds of Penicuik House, and it was a treat indeed to see the magnificent trees in every part of the domain. The rising ground especially that slopes gradually from the side of the river Esk upwards to a height of several hundred feet contains many noble trees, which when seen in perspective appear massed together in beautiful irregularity; in fact, the whole of the grounds are beautifully wooded, and viewing them as I did, just as the setting sun cast its crimson shadows around, compelled me to linger and gaze on what was to me a spectacle of grandeur.

On leaving here, and following the banks of the Esk, I came to Roslin (or Rosslyn, as it is by some called), with its waterfall or linn, its ancient chapel, and ruinous castle. Here my attention was rivetted to a fine old yew tree, the largest in the trunk and circumference of branches I have ever seen. It is said to have been planted in the reign of David Earl of Huntingdon (afterwards King of Scotland), in the year 1140; but notwithstanding its great age it is still beautifully green and clothed with branches from top to bottom. It is growing close by the ruins of the old castle, and by the entrance to the vaulted chambers once inhabited by the brave retainers of St. Clair; and the trees no doubt furnished them with branches to form their yew bows and arrows with.

After leaving the tree with its surroundings, I strolled by the river's bank towards Hawthornden, and a beautiful wooded walk it is, with many a fine tree on the hill-side; and returning again to view the linn, and the old chapel, and again from the valley looking up on the castle and its wooded heights, and the shades of evening, with a beautiful full moon rising, caused pleasurable sensations that possibly I should not have experienced unless I had been a lover of trees and all their rustic belongings. Now I daresay some of your readers will say, "What does all this prose and verse tend to?" Just this: let all who have land to spare for the purpose, plant a tree on every spare occasion. They will not only enjoy its beauty in their lifetime, but will confer a lasting pleasure on future generations; for trees were made for enjoyment and pleasure, and made, too, before man; and our dear island home would be shorn of its greatest beauty were our woods and forests to be cut down and not replaced. So, plant trees; they will grow when we are asleep, and protect us from sun and wind when we are awake.

Albert Nursery, Bayswater, W.

JOHN BURLEY, F.R.H.S., &c.

Literature.

The Manual of Botany for March contains a report of the London Botanical Exchange Club for 1866; a Tabulation of the World-distribution of British Ferns, by J. G. Baker, Esq.; a Revision of the Section *Tomentosa* of the genus *Rosa*, by A. Deseglise; and notes on various new Continental botanical works.

The Ladies' Treasury for March is undoubtedly the best Number we have yet seen. It abounds in variety, is original everywhere, and is most elegantly got up. The story of Frøbel's Kinder Garten is one of the most interesting amongst many excellent papers. There is a capital sketch of Cervantes. The series on Furnishing Houses will be found of great value by young housewives, perhaps also by those who are not young, if we may be so ungallant as to suppose there are any such. The coloured print for a flower design in woolwork is in good taste, and beautifully produced. None of our lady readers should abstain from reading this admirable monthly.

The Intellectual Observer for March is scarcely so lively and varied as usual. The principal articles are on the "glass-rope" Hyalonema, an extraordinary sponge which spins a rope of crystal threads—this is by Professor Wyville Thomson; The Star Chamber, by F. W. Rowsell; Indian Insects, by the Rev. R. Hunter; The Climate of Great Britain, by R. A. Proctor; The Vegetable Sheep (*Roualia eximia* and *Haastia pulvinaris*) of New Zealand, by Mr. Jackson of Kew; and a further contribution to the attractive series of papers on "Pleasant Ways in Science." The coloured illustrations represent the Hyalonema and the Vegetable Sheep.

The Floral World for March opens with a paper on collecting and selecting, which will interest those amateurs who are influenced by the "revival" of true taste in gardening. These papers are devoted to Sub-tropical Plants, Effective Bedders, Propagation of Plants by Cuttings, Roses for 1867, Ferns and Fern Cases, the Flower of the Yucca for Display, and a new feature, called the "Finger Post," under which selections are placed.

The Gardener for March contains further contributions on the Flower Garden, Strawberry Forcing, and New Florists' Flowers; also able papers on Orange Trees, Varieties of Vegetables, and Ornamental Kale. The Gleanings of the Month are scarcely so full as is desirable, but they are written in the right spirit.

Correspondence.

ROSES ON OWN ROOTS, AND THE RECENT FROST.—Having had a Number of the GARDENER'S MAGAZINE of last month sent me from the midland counties, with a marginal note against an article on roses,—"How does this accord with your experience?" and "drop the editor a short article,"—I beg leave to begin by giving you an extract from an article I wrote in 1861 on Manetti and brier roses, after the severe winter of 1860: "As a great deal has been written both for and against the use of the Manetti stock for roses, I venture to offer a few remarks on the subject from personal experience. I have grown roses on the brier and Manetti for some years, and until last severe winter found little difference in either stock, for each had its good properties; but the results of our last severe winter have compelled me to give an unconditional preference to the Manetti. My reason for preferring this stock to the brier is, that in spite of the intense cold of last winter I lost only 5 per cent. of roses on the Manetti, whilst on the brier I am sorry to state that my loss was 75 per cent. This fact is, I conceive, greatly in favour of the Manetti as a hardy stock, superior in one of its most essential qualities to the brier. I am also confirmed in the opinion formed of the Manetti from the circumstance that my case is far from being a solitary one. The only drawback, if it can be so called, that the Manetti has is its inclination to throw up suckers; a little watching will, however, obviate this. The brier has the same tendency; besides, the Manetti gives us an advantage over the brier, inasmuch as we can layer roses on the Manetti, and so have them on their own roots if desired; this we can hardly do on the brier." Since then I have not lost one rose on the Manetti, but several on the brier. This winter has been very severe here. I cannot say precisely how low the temperature was in my garden, which is situated in the suburbs of this port, and is protected from the north and north-east winds, because the glass that registered the lowest degree of cold was broken just before the frost set in, and I had not got it replaced; however, I believe it was close upon zero. Now with this severity of weather I have not lost a perpetual rose on the Manetti, and I have only lost two on the brier, Empereur de Maroc and Cardinal Patrizzi; to lose a rose on its own roots would be a remarkable occurrence with me. As I have said, you can layer roses on the Manetti, and so have them in due time on their own roots. Now I have all my Manetti roses on their own roots, except those which I have got in last November and the year before. I will have no roses that are not low-budded; these, of course, I plant two inches or so below the surface. After the second year of planting I take them up and almost invariably find that the rose has rooted just above or close to the union; I then cut the Manetti entirely off, and as a consequence have roses on their own roots: some with which I have so operated I have taken up in a year or two after, and separated into three good fibre-rooted roses. The propagating by layering is an easy process and pretty certain, but I prefer propagating from cuttings under bell-glasses in the open air, which I do most successfully, inasmuch as I consider it bad work if I don't strike three-fourths of all I put under the hand-glass. I have now in green leaf cuttings which I put under the glass last summer that have had no protection but the bell-glass (I may observe that it is quite delightful to see them after the severity of the winter). I have several groups of roses of all kinds which I have struck from cuttings put under glass in the years of 1863, 1864, and 1865, that have not yet been transplanted, and fine strong plants they are; not one succumbed to the winter's frost; last summer they looked splendid in the groups—of all kinds and colours, from the deepest scarlet to the purest white we have. Many of these I purpose sending to a young rosarian near Birmingham, to give him an extra stimulus in the growing of roses, and let him see what may be done with enthusiasm, attention, and perseverance. In fact, I am glad to say that I am well repaid for years of untiring personal attention and devotion to the rose, which have enabled me to grow and bloom it almost as I choose. Last July I had as perfect a bloom, or rather a bloom of as perfect-shaped roses, as ever I saw, except perhaps at the rosery of that renowned rosarian, the Rev. W. F. Radclyffe. Whoever is wishful to be a successful rosarian must do his own work; his ardour must be such that it will not allow him to waste his hours in morning slumbers, when the aphides and grubs are destroying the vitals of the blooms which he is so anxiously looking forward to enjoy; neither must he be afraid of dirtying his hands or pricking his fingers, for he must plant his roses, prune and manure them, &c. As for myself, I do everything but the laborious work. I will just observe that the rose, the carnation, the pink and picotee, are all the flowers in my garden I particularly care to see, but the rose is the jewel of them all.

"She will meet you with a smile at morn,
She will lull you to repose;
The poet and the painter's flower,
The everlasting Rose."

I am glad to say that Maréchal Niel is a hardy hero. I have two plants that have been exposed to the severity of the winter and are looking well; and I have also two cuttings under bell-glass that were put in last summer, and are now in leaf. It promises to be a hardy rose, and I am glad of it, because in point of colour it is a rose that has been so much desiderated, and one which I have looked for for years to our good rose-producing neighbours the French.

Derringham, Spring Bank, Hull, March 9th, 1867.

JOHN MILNE.

It seems that the experience of all rose lovers and growers is unanimously in accordance with your often expressed opinion, that the best and only safe way to grow roses is on their own roots. Now, for the satisfaction of yourself and those who take an interest in this subject, I may as well mention that my garden is on the slope of the hill running up to Blackheath; aspect of the slope south-west, and subsoil gravelly. Capital situation, no doubt, for such roses as can stand London atmosphere, and at first impression probably you even will say that I cannot have had the annoyance of losing many roses. But I have lost several, and amongst them one *Maréchal Niel* on own roots; *Climbing Devoniensis* (matted up) killed down to last two buds; one *Maréchal Vaillant* dreadfully cut up, and even *Sénéateur Vaisse* blotched with bronze frost-marks. The fact is, the susceptibility of the rose to frost depends on the soundness of the constitution of the plant, its position, and its being in a state of rest at the time of the frost. Thus my *Maréchal Niel* was a mere infant of a plant, too small; another escaped with little injury because it was stronger and finer altogether. An *Ophir* on brier, a fine dense head, in a drafty place, perished ingloriously; and not far off a *Géant des Batailles* on own root was cut down to the snow-line. *Maréchal Vaillant* and *Sénéateur Vaisse*, fine plants in sunny positions, having grown on until long after all others, were not at rest, and so suffered

for their tenuity; while the well-known tender *Jaune Desprez*, from which I had stripped the leaves, after giving it a good lift in early November, was positively discovered by me the other day beneath its loose protecting mat as sound as *Charles Lefebvre*. My own-root roses are now showing their first leaflets, and I look forward to their fully vindicating your teachings.

VIATOR.

STOCKS, TO DISTINGUISH SINGLE AND DOUBLE.—I notice your observation upon Stock-growing, and will, if I may be permitted, although not a professional or professional gardener, make a few observations, not to controvert what you say exactly. I am in the habit of having a bed of stocks, which always are very fine. My plan is to sow the seed in rich earth, and when up, if crowded in the pan, transplant the whole of them, taking up with the blade of a knife (a stick might do, but it is apt to bruise the roots), care being taken to lift, not cut off, the roots. The transplanting is into seed-pans, about an inch apart every way; the plants I leave in the pans until they have four or six leaves, or until I want to plant them out, having prepared the bed as you say. The top-dressing you speak of on planting out I think an improvement. When I am planting out, I lift every plant and examine the root, and all the plants which have roots like a carrot I reject, but all which tuft at the root I plant; and the result is, in a hundred plants I rarely have a single-flowered one. I only want about one hundred plants, and my object would be defeated in having single flowers amongst them; and by the mode above spoken of I invariably get a bed of double flowers. This may be a hint, in your hands, with your great knowledge, worth trying. I have never found it fail, and for experiment I have planted the carrot-rooted ones by themselves, and all have been single. As a rule, I find the forked roots are double flowers, the carrot-rooted single. I am unwilling to arrogate to myself the notion of having made a discovery, for I may have met with the hint somewhere, or have been told, but if so, where or how I cannot say; but to every person I have suggested it appeared to them new, and only last year a gardener gave me a number of stock plants which he said were something excellent. Of course I was obliged; but on looking at the roots I told him I feared he was mistaken, and that I believed every one was single, and so they proved. This was a man who is considered to be very skilful, and has the charge of a large establishment. His trial was the same as mine; all his were single. He then remembered what I had said, and desired my secret. If you think my observation is worth a trial, try it, or make use or not as you please of it; but if it is a matter that is of consequence to market growers, then I think it, in experienced hands, is worth a trial, and on the trial I believe the result will prove satisfactory. This letter is written, not for publication, but for your information and for that of your readers, if you choose to frame a paragraph, always supposing there is any worth in your estimation in the suggestion.

S. B.

[It would be most unwise to frame a paragraph with so clear and interesting a statement ready to hand, and so we give the letter in full, merely suppressing the name and address of the writer.]

HORSERADISH.—You must really have the goodness to pardon my inquiry whether in your directions under the Calendar of Operations for Kitchen Garden for March 2nd, you have not made a mistake in stating that the crowns of horseradish should be planted 15 inches deep, and 6 inches apart. I should not have troubled you with the inquiry, but put it down as a typographical error, had I not the recollection of having read the same instructions in the GARDENER'S MAGAZINE some time back. I should have read it 6 inches deep and 15 inches apart, although 15 inches apart would seem rather wide.

BURIED ALIVE.

[Very few people know how to grow horseradish, and hence it is seldom we see sticks a foot long, an inch thick without a fork or fibre, and so free from woodiness that they may be all scraped away, and if properly scraped become like white foam, emitting a delightful fragrance, and possessing a delicious flavour. Having given our way of growing it, we have taken the trouble to copy from a few well-known authorities their several directions, and leave "Buried Alive" to take his choice amongst them. We repeat, however, that horseradish fit for a gentleman's table is produced in but few gentlemen's gardens.]

Abercrombie's Method.—As the green crowns must be left on the best roots to render them marketable, you must obtain sets from the offsets that arise from the bottom or sides of the main root, and of which take cuttings of their tops two or three inches long, or use the tops and crowns of the old roots when taken up for use, in cuttings of the above length. Choose an open situation, and as light and deep a soil as the garden affords. Then proceed by dibble-planting, in the following manner: Being provided with a long dibble, beginning at one end of the ground, range a line crossways, and with the dibble make holes about 12 or 15 inches deep, and be careful to make them all of equal depth, which you may do by making a mark upon the dibble, and so thrusting it always down to that mark, making the holes 6 inches asunder, dropping as you go on one set or cutting in each hole, with the crown, &c., upright, taking care to close the holes up properly with the earth; and let the rows be 2 feet asunder. When the whole is planted, the ground may be sown with spinach, which will come up time enough to gather off in April and May, and give the horseradish full room to grow.—*Every Man his own Gardener*.

Judd's Method.—After having fixed on a spot of the garden sufficient for the crop I intend to plant, it is trenched full two feet deep, either with or without manure, according to the state of the soil, which, if in itself good, requires no enriching; but if it is poor, some good light manure ought to be added to it, and this must be carefully laid into the bottom of each trench; for, if not so done, the horseradish, which always puts out some side roots, would send out such large shoots from the main root in search of the dung contiguous to its sides as to materially deteriorate the crop. After the bed is thus prepared, plants are procured by taking about three inches in length of the top part of each stick, and then cutting off about a quarter of an inch of this piece under the crown, so as to leave no appearance of a green bud. Holes are then made, by means of a dibble, eighteen inches apart every way, and sixteen or eighteen inches deep; the root cuttings, prepared as directed, are let down to the bottom of the holes, which are afterwards filled up with fine sifted cinder-dust, and the surface of the bed is raked over as is usual with other crops. This is done from the middle of February to the middle of March. It will be some time before plants appear, and the operation of weeding must be done with the hand and not with the hoe, till the crop can be fairly seen; afterwards nothing more is requisite beyond the usual work of keeping clean, till the taking up of the crop, and this may be done at any time during the winter months.—*Baxter's Library of Agricultural and Horticultural Knowledge*.

Mr. Knight's Method.—Mr. Knight premises that the ground be previously trenched three feet deep, and that there be two or more beds side by

side; each bed is to be four feet wide, with one-foot alleys between the beds. Nine inches of soil is to be taken from the top of the first and laid on the surface of the next adjoining bed; then the first bed is to be trenched and planted with crowns only, the trenches to be fifteen inches deep, and the sets nine inches apart each way. The trenches are to be planted one after the other, but the alternate beds only will be cropped; thus, if there be four beds, the first and third will be planted, the second and fourth will be vacant; and, moreover, their surfaces will be higher by nine inches than the surface of the first and third. The plants must be kept free from weeds, and as soon as the leaves decay in autumn be carefully raked off with a wooden-toothed rake. In the following February, eighteen inches of the earth of the unplanted beds must be laid as light and equally as possible over the beds that are planted; then trench and plant the vacant beds exactly in the same manner as before directed. The following autumn the first planted horseradish may be taken up, by opening a trench at the end of the bed to the bottom of the roots, so that the sticks or roots of horseradish may be taken up entire and sound, which for size and quality will be such as have not been generally seen. The following February the one-year old crop will require additional earth as before (eighteen inches), which must of course be taken from those beds that are vacant, which, when done, if the ground appear poor or unlikely to produce another vigorous crop, they must have a coat of manure.—*Horticultural Society's Transactions.*

JUDGING AT SHOWS.—This is rather a delicate subject to approach, Mr. Editor, but I do not intend to interfere with judgment more than belongs to horticulture or floriculture. I think you, and many of your readers, are aware, and will admit, that justice is not fairly administered at—shall I say, provincial exhibitions only, or at exhibitions generally? I have been to many exhibitions, and have very, very often heard of some dissatisfaction respecting the awards of prizes (that, you will say, is universal, for gardeners couldn't do without grumbling); however, I think there is very often just cause for it. I will give you an example of justice at a country show held in the Midlands. A prize of £10 was given for roses; there were but two competitors—one a large grower, the other a small one. The discerning reader will say the large grower was first, of course, and the small one in his proper place. Now it so happened that they were not in their proper places, for the first prize lot were bruised and beaten to tatters, many of the blooms were very stale, and a good number of them *could see for themselves.* The second prize lot were very clean, good size, the centres first-rate, and, above all, as fresh as possible; the only fault they had was that they were a little too close together. I could give you many cases like this, but will not take up your valuable space with them. I know if I could ensure satisfaction to all exhibitors, I should soon be in a very enviable position; but I think I can state how there might be great improvement. We very often get judges who are gardeners to some lord or duke's place. I heard a secretary say last year, "It sounds so well if we can but get men from places like those." Now, with every respect to gardeners who hold nobleman's places, I do not hesitate to say that it is one of the greatest errors ever committed to appoint men merely because they are in large places. I have frequently observed where such men have been selected plants and flowers have not had justice done them. Last autumn I was with a gardener who holds one of the best places for fruit hereabouts. After he had awarded prizes to dahlias and hollyhocks, says he, "How do they do to grow them so fine? Which do you think are the best flowers? Are they much trouble; for I do not know anything at all about them?" If those who are judges do not know a good flower or plant, how is it possible for them to award prizes fairly, though good cultivators are not always good judges. Fruits and vegetables, I must say, are better adjudicated; but I have seen errors in them. For competitors of the upper and middle classes, quality should be the first point; but for cottagers, productiveness and usefulness must, or ought, to have the preference. In a cottagers' class last summer I saw twenty or thirty dishes of the King of Flukes potatoes passed over, and prizes awarded to those which perhaps might be better in flavour, but could not touch them for productiveness and usefulness. What I should propose to managers of societies, is to select men who are capable of awarding prizes honourably and fairly, and pay them well for it; for cheap judges are like other cheap articles, often worthless. Farther, I would adopt a standard for things to be grown and shown by, so that cultivators in a great measure might be their own judges. It is a well-known fact that manufacturers, engineers, and stock breeders and feeders have standards of what perfection ought to be; and if horticultural societies were to lay down a code of rules for their several productions, exhibitors would be glad to pay for the trouble and expense they (the society) might be put to, so that they might feel themselves satisfied with some degree of safety in growing whatever they might take in hand, instead of the uncertainty which they have to contend with at the present time.

J. T., near Leicester.

* * * A typographical error of the purely "unavoidable" class occurred in page 106, last week. In the reply to J. W. T., on propagating the Weeping Birch, "varieties of fir" should read "varieties of birch." The error no doubt corrected itself in the minds of most readers.

Replies to Queries.

Improving a Lawn.—Redland.—To get rid of worms is neither an easy nor a desirable matter. We have seen them completely extirpated by scd dening the ground with a solution of corrosive sublimate, but the grass was worse afterwards than before. Usually a watering with lime-water brings out a great many, especially if the watering is done during mild moist weather; and if that is followed with occasional thin sprinklings of nitrate of soda, a good thick growth of grass is produced. As your lawn was drained and re-turfed last autumn, it is not possible it should look well now. Probably as the season advances it will improve. Do not have it beaten till quite the end of April or some time in May, when perhaps beating it level will improve it. At this time of year beating would only smash the half-alive grass. The mixture of sand, loam, old mortar, and guano you propose to sift over it will certainly do it no harm, and if you put on but a thin coat at a time, will probably do good. Perhaps all you need is patience.

Flower Beds.—Amateur repeats the query which was answered Feb. 9, p. 61. So many correspondents sign "Amateur," "Constant Reader," and "Subscriber," that a little confusion must be expected. Correspondents have the remedy in their own hands.

Floral Vignettes.—Lady H. S.—They depend more upon taste than skill; we have seen some that were equal to coloured pictures. Small yellow flowers, such as tormentil, nicely pressed sprigs of pimpinell, yellow violet, and slender grasses and mosses, are the kinds of plants best adapted

for the purpose. They should be carefully dried between folds of blotting-paper, and after that taste must be exercised in disposing of them. To fix them in groups on note-paper with a brush dipped in gum is quite a simple matter; but to do it with effect depends upon taste and practice.

Annals for Cold Soil.—B.—The best annals for a cold clay are any of the showy Californian kinds, sown in pans in a pit or frame, or on a gentle hotbed, and planted out when the ground is warm. If you grow *Oxalis rosea*, *Hunnemannia*, *Nemophila maculata*, *Leptosiphon*, or *Fenzlia dianthiflora*, or *Ipomeas*, get them forward in pans, and do not plant them out till May. Give preference to the crimson, purple, and white candytufts, *Nemophila insignis*, *Campanula speculum*, *Venus's Navel-wort*, *Silene armeria*, *Kaulfussia amelleides*, *Viscaria oculata*, *Gilia rosea*, *Escholtzia crocea*, and peony *Poppy*, and others that we have described as suitable for autumn sowing, as they are the hardiest. If you sow any of these the first week in April, you may expect them to bloom nicely in June and July.

Cockcombs.—J. W. T. B.—Sow in a brisk heat, prick out as soon as large enough to handle, and then pot on, never allowing them to become pot-bound; soil sandy loam and very rotten dung; keep in hotbed till the combs are nearly full grown, and use manure-water pretty freely. Remove to greenhouse when combs are fully spread. Throw away any that are ill-shaped or badly coloured; you will soon be able to determine which will prove the best for keeping.

Roses dropping their Blooms.—R. Baxter.—*Devoniensis* and others that are in a strong clay, and drop their blooms, will behave very differently if you temper the soil with a liberal admixture of turfy peat, leaf-mould, old dung, and sand. These ingredients, with yellow loam, all in equal proportions, make a first-rate mixture for tea-roses. Your soil is too cold and too heavy, and they show their indignation by casting their blooms.

Mathiola bicornis.—C. S.—This plant is a crucifer, native of Greece (Don, *Dyehlamydeous Plants* I. 153. Smith, *Prod. Fl. Græc.* II. 26). Leaves hoary, pinnatifid, siliques torulose, furnished at the tip with two acute horizontally-spreading spines, from which it takes its name. Flowers purple; grow the same as stocks in a light soil. It is the two-horned podded stock of gardens.

Sphagnum.—R. R. R.—This is a moss which abounds in most hoggy places, and generally grows in spots where it is covered with about two inches of water all winter, in sappy unsafe ground. There are a few spots on Hampstead Heath where we can always obtain a supply, and that is the nearest spot we know for it near London. It is a gray moss of coarse texture, very distinct in character, and when bitten between the teeth yields a hitter taste. It is useful for a hundred different purposes in horticulture, and is largely used by nurserymen to pack plants in, as it retains a certain amount of moisture when dry to the touch, and is so astringent that it prevents decay of the plants packed in it. You can obtain fern-spores of the first-class seedsmen; any who advertise in this work will supply you.

Ferns for Cover.—Sir T. H. S.—The reason why ferns do not grow in your covers is probably that the soil does not suit them, and this is the more likely as they grow "admirably two or three enclosures off." The best fern for your purpose is the common brake, which will grow in almost any soil, but most freely in a damp peaty earth. It has been said in books that the brake cannot be easily propagated, but we have been overrun with it through the introduction of pieces of the roots to the garden in bog-earth from Wanstead. As the bog is always chopped to the size of potatoes when used, it is evident that moderate-sized pieces of the brake-roots will grow. If we had to manage your coppice, we should select a certain few favourable positions, and open circular trenches, from which we would remove the earth to a depth of eighteen inches and a breadth of three feet. Those trenches we would fill with a mixture of surface parings of turf, charred rubbish, moss, rotten wood, and any other peaty material we could lay hands on. A few loads would go a great way, as a portion of the soil taken out could be mixed with it if loamy. Plant these belts with *Pteris aquilina*, *Lastrea filix-mas*, *Polystichum angulare*, *Athyrium filix-femina*, and *Scelopendrium vulgare*. The first is the most important, as it is real game cover, and will grow almost anywhere. If you cannot get a supply of plants in your own neighbourhood, a nurseryman will supply you by the hundred or thousand. Do the work at once, and finish it off before the season advances towards summer.

CATALOGUES.

Mrs. DIXON, 48A, MOORGATE STREET, LONDON.—*Select List of Kitchen-Garden, Farm, and Flower Seeds for 1867.*—Contains everything in request at this time of year, and is admirably arranged for reference.

SUTTON AND SONS, READING.—*Farm Seed List for 1867.*—This excellent list is embellished with beautifully finished coloured figures of Sutton's New Intermediate Mangel Wurzel, a fine, solid, yellow root of an oval form, and Sutton's Champion Swede, one of the best for cropping, storing, and resisting disease.

JAMES BACKHOUSE AND SON, YORK.—*List of Alpine Plants and Hardy Perennials, 1867.*—For lovers of floral beauty who have souls above flat bedding and Kidderminster carpets, this is something more than a list of plants; it is a sort of "key to golden palaces" and "gate unto that paradise" which is reserved for the thoughtfully tasteful and the tastefully refined. We shall have to notice this again.

DOWNIE, LAIRD, AND LAING, 17, FREDERICK STREET, EDINBURGH, AND STANSTEAD PARK, FOREST HILL, LONDON.—*Catalogue of Garden, Flower, and Agricultural Seeds, &c.*—This is arranged so that customers can fill in the quantities they require without having to write the names of things. It is at once, therefore, a catalogue and an order-sheet.

STUART AND MEIN, KESLO, N. B.—*Select List of Fruit Trees.*—This is one of the best of lists for the northern parts of Britain, and it is prefaced by an admirable article on the cultivation of Dwarf Apple-trees, by the Rev. R. O. Broomfield, accompanied with a selection of varieties for the colder parts of the isle.

ARTIFICIAL WOOD.—An important branch of industry has recently sprung up in Rhenish Prussia. It consists in the manufacture of various articles from refuse wood and sawdust, which are agglomerated by a cement, the exact nature of which is not stated, and then pressed in moulds, so as to form covers for photographic albums, small picture-frames, rosettes, and other ornaments for the use of cabinetmakers, &c. For the last-mentioned articles the composition is stained to imitate ebony, mahogany, walnut, and other woods. The composition, or "seifarine" as it is called, may be sawn, cut, drilled, attached together by glue, and bent on hot plates. It may be polished with oil or French polish, and may be varnished and gilt. A similar composition was manufactured in France a few years ago by mixing fine sawdust with blood, and submitting it to the action of a hydraulic press.

The Gardener's Magazine.

SATURDAY, MARCH 23, 1867.

GARDENERS' WAGES were the subject of very active discussion two years since, and it appears, if we may judge from the proceedings of a meeting reported in the present sheet, that another discussion may be looked for on the same subject. We use the term "diseussion" somewhat inadvisedly, for the utterances are all on one side, and the so-called discussion amounts to a collective protest by gardeners themselves against the insufficiency of their scale of remuneration. We have not yet heard a vigorous defence of the prevailing rate of wages from any employer; the verdict therefore goes by default, and on both sides it appears to be agreed that gardeners are not well paid, and that the time cannot be far distant when some amendment will take place. It is equally our interest and our duty to be impartial; our clients comprise employers and employed, and the interests of both are, by consequence, to be made note of at the head of our brief. Now we have no hesitation whatever in saying that the interests of both are bound up in this question, and that if the rate of wages is lower than strict justice demands, the employer is as great a loser by it as the employed. There is nothing gained by injustice, nothing gained by an ungenerous policy, no advantage worth having can result from labour that is unfairly compensated. These postulates apply to the whole case of employment in any and every capacity, but they apply with peculiar force to the employment of the gardener. Here is an occupation that cannot be governed by mechanical rules—an occupation demanding personal energy, peculiar intelligence and tact, and as much earnestness and honesty as any kind of labour in which men are engaged. The embellishment of the house and the table are matters largely in the gardener's hands: if he does his duty, the family enjoy cheerfulness and plenty, in so far as it is possible for the gardener to minister to their moral and physical necessities; but if the gardener neglects his duty, the garden itself becomes a nuisance and a vexation, and the good fruits of the earth, that should so emphatically vindicate the gardener's art in the social circle, are conspicuous by their absence, and the gardener's wages are all thrown away. We wish to avoid the appearance of boastfulness in regard to either of the parties to a consideration of this sort; but we do feel bound to say that, *as a class*, the gardeners are exemplary for faithfulness, intelligence, and application to their duties; and the employers of gardeners, *as a class*, comprise the best-intentioned and most generous-hearted people in the country. English gentlemen and gentlewomen are the employers of gardeners, and to such we may appeal with the best assurance of a fair hearing and of perfect justice in the end. We ask them to ponder in a kindly spirit the fact that as a rule gardeners are paid at a lower rate than the practitioners of other kinds of skilled labour; that they rank equal or superior to building operatives in intelligence and skill, but are considerably below them in respect of hours of service and average pay. There are grades of honour in gardening as in other occupations; the mere labourer cannot and does not expect to be paid at the same rate as the skilful artist, but in respect of both present remuneration is at a low ebb, and the prospect of advancement is neither bright nor extensive; it must rest with the gentlemen and gentlewomen of England to improve the gardener's lot, and open the way for his attaining to a better position in the scale of social life.

We beg pardon of all the gardeners for the last observation. If second thoughts are best, we will say that it does not rest so much with their employers as with *themselves* to effect an improvement in their position. If societies formed to promote good fellowship, on the basis of pure decorum and mutual improvement, were established in every considerable district—town, village, or parish—after some such model as the West London Gardeners have adopted, the gardeners as a body would soon attain to the social rank they are entitled to as essential members of the body politic. They have never yet been united; even the United Society has proved a mockery, for it has become a clique of six bent on the practice of the basest toadyism. It is real *unity* that is wanted, in the spirit of manly independence and uprightness and true mutual regard. One of the best qualities in a man who is dissatisfied with his lot is *self-respect*, which will prevent his bowing down before a brazen image or an idol of wood, as we have

seen gardeners do in these degenerate days, and secure for him perfect justice, which is better than patronage, and fair play, which is better than any gift. The love of patronage is the curse of the gardening community, and of some other communities of the industrial order. But this curse is fast being removed by the improving intelligence and independence of the order; and we hope to see, as one of the most marked of the moral features of horticultural industry, the observance of a proper respect for wealth and superior social status, without a shadow of cringing or of fawning for patronage. The cultivation of self-respect implies the practice of habits of sobriety, thoughtfulness, thrift, and every principle of personal honour, and it demands the rendering unto Cæsar whatever is Cæsar's due of time, strength, skill, obedience, and deference, and all these things must come from within the man, and be the evidence of his character and intentions. Union for mutual improvement and the mutual advancement of pecuniary interests may be made the corner-stone of a new and better order of things for all who live by garden labour.

Let us not forget, however, that during the past two years something has been really done to improve the circumstances of the operative gardener. Most of the great London firms have advanced the rate of wages, and this without being put under pressure. This fact should encourage those who have as yet in no degree participated in the improvement. Let them persevere, using such moderate means as cautious men will approve, and let those who are well off in respect of both employment and wages give assistance cheerfully to their brethren who are not so.

HYDE PARK.—In the House of Commons lately, Mr. Alderman Lusk asked the First Commissioner of Works if he thought it desirable to continue the elaborate horticultural embellishment of the Park-lane side of Hyde Park at considerable public expense, while the Bayswater side and Kensington Gardens were, in the same respect, comparatively neglected.—Mr. NICOL inquired whether the unsightly fence surrounding the park could not be removed, and whether the contractor could not be induced to complete the new railing before July, 1868, and whether it was true that the price of those railings was to be £40,000.—LORD J. MANNERS. Assuming, as I cannot do, that the adjectives and adverbs of the worthy alderman's question are correct, I can only answer it in the affirmative. With respect to the question put by the other hon. member, there is no doubt that the contractor might be induced to hurry on the work, if the public are prepared to expend more money in paying him for so doing. But considering how and by whom the railings were destroyed, I am not prepared to recommend the House of Commons to make any additional outlay. With regard to the hon. gentleman's question, it is one of the most incorrect statements I have ever heard in the House.

KEW GARDENS.—In the report by Dr. Hooker on the affairs of the Royal Gardens during 1866, it is stated that the number of visitors during the year was 488,765, being 14,000 less than the total for 1865. This is attributed to the bad weather during June, July, and September. The palm house is described as having been rearranged, and the fern and aroid houses are in the finest condition, but the tree ferns are so crowded that the public cannot see them. The collection of succulents has been increased. The orchids are improving; but the collection is far below what these gardens should possess. The hardy herbaceous plants are in a very unsatisfactory state, but they are being rearranged under a new foreman. The temperate house has been replanted, and a grand effect produced by arranging tree-ferns, half-hardy plants, &c., down the centre. The ornamental trees in the pleasure grounds are in a bad state, the trees dying by hundreds, and a considerable outlay will be required to arrest this mortality, and effect necessary improvements. Numerous important works are in progress, and various changes have been made in the staff and administration, the full benefits of which are not as yet realized. Upon the whole, the report is a gloomy one; but it affords reasonable ground for hope that these gardens are in process of restoration from a long accumulation of neglect.

WEST LONDON GARDENERS' SOCIETY.

On Wednesday, March 13, a meeting of gardeners was held at the Shaftesbury Club House, 35, Princes Street, Notting Hill, for the purpose of establishing a society the object of which is to promote mutual defence and advancement of their interests. The chair was occupied by MR. SHIRLEY HIBBERD, who opened the proceedings by stating that he was glad at all times to assist in any movement of gardeners intended for the advancement of their art and their own personal interests, when a straightforward and plain-spoken course was taken to carry their proposals into effect. He was not aware of the course it was intended to pursue, but no doubt he should learn from the resolutions; and he was only anxious, as chairman, that those who had to speak should have a courteous hearing, and that whatever was decided upon in reference to the formation of a society should be with circumspection; for it was the fate of many societies to die young, and frequently the elements of discord were in them from the beginning, so that it was impossible they should prove of any lasting service to their founders. As to the general proposition to establish a system of mutual

instruction, it was entitled to the approbation of all right-minded men. He believed they might benefit more by a well-conducted mutual improvement society than by seeking the assistance of the most learned professors; they would find, in fact, that one of the quickest and surest ways of learning something was to make an endeavour to teach it. Every man's experiences differ in some respect from the experiences of every one else engaged in the same pursuit or business. Every one amongst the many gardeners then present could tell his friend or neighbour something worth knowing, if experiences were exchanged freely. It is the thoughtful observant man in every business who is the most successful, and this is especially the case in gardening; for it is a business founded on observation, and no man who does not observe,—who does not, in fact, keep himself always at school, in the greatest school of all, the school of Nature,—can ever expect to excel in the cultivation of plants, and it is quite a question if he has any right to attempt to cultivate them, for he cannot possibly succeed. Moreover, the observing and reflecting man will find his business full of delights; he will find it a cheerful, elevating occupation; but the careless man, following his calling as a cart follows a horse, or as a machine moves because it is driven by steam or some other power, will find no pleasure in it—will be without a stimulus to exertion or improvement—will not only not prosper in life, but will not deserve to prosper. This mutual improvement scheme was opportunely proposed, for the working classes were waking up throughout the land, and the subject of their political rights and privileges had become of so much importance that their consideration at the present time constituted an historical epoch. It was a happy thing for this country—for its institutions, its liberties, its prosperity, and progress—that the masses of the people are claiming to exercise a due share of influence in political affairs. It was a time, however, in which working men should put in action all the discreetness they possessed. It was not for the idle or the dissolute to say much about the wrong involved in the exclusion of the artisan and labourer from the franchise; the proper declaimer against that wrong is the sober, industrious, intelligent, generous-minded man, who, by his example and good life, can put to shame those who would deny to him the right of influencing directly at the polling-booth the destinies of this great country. He hoped that if they should form a society, it would be the means of bringing together the gardeners of the district for mutual aid in whatever was worthy to be promoted. Well-regulated combinations are wonderfully useful, but it needed caution at the outset to prevent the intrusion of the elements of discord, and also to guard the movement against the possibility of assuming a tyrannical form. There is just one thing certain—that working men understand their own wants far better than most of the people who were perpetually preaching at them; therefore working men should meet together, and consider their own interests. Employers will have more confidence in men who cultivate self-respect than in those who are mere drudges, and who pursue their duties in the fashion of a horse that goes round and round in a mill. The great thing wanted for the improvement of our social life—that is, for the advancement of religion, morality, intelligence, and the increase of the comforts of life—was for the working classes to do for themselves what well-meaning but misguided patrons had endeavoured, but had failed, to do for them. Self-improvement is the best of all improvement. The search for knowledge gilds the pill of life, and those who exert themselves for the benefit of their fellow-men will assuredly benefit themselves by the endeavour.

Mr. John Burley moved the first resolution: "That there exists a necessity for an increased co-operation amongst gardeners, for their individual advancement and mutual benefit." He said, I am sure it will be agreed by all present that a society having for its object to promote co-operation amongst gardeners is very much wanted. As a class we—that is to say, the gardeners—are second to none in general intelligence and love of our profession; and there is a great deal of good-feeling amongst gardeners that requires to be brought out, and afforded opportunity for expression, both in words and deeds. Take notice what happens when gardeners take it into their heads to visit some place where they have heard there is something good to be seen, and how generously they are always received, and how freely they are invited to walk round the garden and greenhouses, and see the best and the worst the place has to offer them. Wherever and whenever gardeners meet, the spirit of freemasonry—that is to say, the spirit of good-fellowship and large-heartedness—is manifested; and it is a pity that this generous feeling should have so few opportunities for its exercise than at present. The society to be established on the present occasion is intended to foster a brotherly feeling, and afford opportunities for gardeners to compare notes with each other, to exhibit their produce, and perhaps read essays on their cultivation, and engage in friendly discussions on matters affecting their interests. The diffusion of knowledge amongst us will tend to raise us in the social scale to the position we deserve but do not yet enjoy. A great deal has been written and said of late on the pay that gardeners receive, and, as an employer of labour and skill, I must say there is room for improvement in that direction. A gardener's work may be said to be never finished. Sometimes he must be at it extra early, and at other times extra late, and now and then early and late together, as the exigencies of the season, fashion, and weather require, and always a bit of Sunday work as well that cannot be avoided. Then it is a situation of trust. The gardener is surrounded with valuable property; he has more or less to do with the house, and exerts a considerable influence for or against the comfort of its inmates. Now, I say that, considering these things, they are miserably under-paid, worse, in fact, than most artisans; worse, too often, than coachmen and footmen, ay, and sometimes worse than the cooks for whose gracious approbation they submit well-grown cauliflowers, tomatoes, and the rest of the good things that, with much anxiety, are brought to perfection in English gardens. Combination is essentially necessary, especially in regard to the financial part of the question. Mind, I don't mean that you are to combine and strike for wages, but I wish you to show your employers that a fair wage is due to you for the anxiety and skill you are required to exercise in the care of his property. In conclusion, I beg to state, sir, that the business of this society has been thus far conducted by a committee of twelve gardeners, including myself, and we shall not mind the time and money we have expended upon it, provided the objects we have in view are promoted by our labours.

The resolution was seconded by Mr. Thomas Burley, and supported in an effective speech by Mr. O'Dell, and was then agreed to unanimously.

The Secretary then read to the meeting a series of rules that had been framed as the basis of the proposed society, after which Mr. M'Elroy moved that these rules be adopted. This was seconded by Mr. W. Hills, and carried unanimously.

The usual vote of thanks to the Chairman terminated the proceedings.

The following are the rules agreed to:—

1. That this society be called the "West London Gardeners' Mutual Protection and Improvement Society;" its object being the advancement of horticulture, and the improvement of the circumstances and prospects of persons who follow it as a business.
2. That gardeners alone are eligible to become members of this society, and only those who will be admitted who are known to be persons of good character.
3. That the subscription be at the rate of four shillings (4s.) per annum, to be paid quarterly or yearly in advance. Members in arrear to be fined twopence (2d.) per month while their subscriptions remain unpaid.
4. That the quarterly meetings be held on the evenings of the first Wednesdays in January, April, July, and October, in the Shaftesbury Club House, 35, Princes Street, Notting Hill, to commence at 8 o'clock, and to close at 10 o'clock; the meeting in January to be also the annual meeting. That at these meetings essays on gardening subjects may be read, and specimens may be exhibited by members. That the reading of an essay shall occupy not more than fifteen minutes, and in the discussion following no one be allowed to speak beyond ten minutes; and no person to be allowed to speak a second time, provided there are others who wish to speak, with the exception of the essayist, who is entitled to ten minutes to reply to the observations that have been made. The committee shall publish a list of the subjects on which essays are to be read, with the names of the persons who offer them.
5. Any person subscribing twenty-one shillings (£1 1s.) in one sum to be eligible for election as a life member, such election to be decided by a majority of votes at a quarterly meeting, when, if the candidate does not obtain a majority of votes, the subscription he has paid shall be returned.
6. That the management of the society be entrusted to a committee of twelve members, they being elected by a majority of the members present at the annual meeting. The treasurer, secretary, and other officers are to be elected at the annual meeting, and are to be, by virtue of their offices, members of the committee. At committee meetings five shall constitute a quorum.
7. That the rules shall be altered only at a special meeting convened for the purpose, and that previous to any such special meeting taking place notice thereof must be given at a quarterly meeting, in order that the members may be fully apprized thereof.
8. That a book or register be kept by the secretary in which to enter the names, addresses, and qualifications of members in want of employment; and members are desired to acquaint the secretary with vacancies occurring, and it shall be his duty to inform the members whose names are on the Employment Register. The expense of postage and any other expenses especially incurred in seeking or obtaining situations for members to be defrayed by the persons benefited.
9. That the expenses of the society be entirely defrayed by donations and subscriptions of members, and any deficit or surplus shall be dealt with by the members at the annual meeting in January.
10. That, to prevent, as far as possible, any cause of dissension, and to promote a brotherly feeling, expressions tending to religious or political controversy at any meeting are forbidden; and the observance of strict decorum is required by every person attending the society's meetings.
11. That all moneys received by the secretary or any other officer be paid to the treasurer within one week of the date of the receipt thereof, and that the treasurer give an account of all moneys by him received or expended at least once a quarter.
12. That no person be considered a member, or entitled to avail himself of any of the privileges secured by these rules, unless his subscription be paid in advance, in accordance with Rule 3.
13. That a library be formed by gift and purchase, to comprise only books that treat upon horticulture and correlative sciences; that for the keeping of the same a librarian and assistant-librarian be appointed in the same manner as other officers at the annual meeting; that the books be lent to members, and that rules be framed by the committee for the entire management of the library, with a view to render it useful to the members generally.

In accordance with the foregoing rules, the first Quarterly Meeting will take place at 35, Princes Street, Notting Hill, on Wednesday the 3rd of April next.

ROSES AND THE FROST AT STAMFORD.

It is only after the effects of such frosts as we experienced during the first week of the present year that amateur rose-growers have the means of discriminating between the consumptive and robust occupants of their Roseries, and nurserymen the opportunity (and I trust they will take a lesson) of disencumbering their catalogues of many third-rate varieties; and although the frost brings its trials for us hotly, "as out of good there cometh evil," it must be somewhat of a satisfaction to all to have the invalids and rubbish so speedily selected and disposed of by such an impartial test. During the nights of the 1st, 2nd, 3rd, and 4th of January my thermometer registered here, in a walled garden at five feet from the ground, and in the open, 23°, 21°, 22°, and 22° of frost respectively. My soil consists of a light, well-drained, highly-manured old town-garden humus overlying the oolite rubble. The garden is surrounded E., N., and W. by high walls and buildings, but open to and sloping towards the south, within a few hundred yards in which direction is an overflowed meadow, at about twelve feet lower elevation. The snow here froze on the branches, and was three inches deep on the ground. Below this line a good many dwarf roses on the Manetti and their own roots are uninjured. I see my lists below do not in every instance correspond with those already published in your paper; but I know that we have suffered here very severely, probably from the situation and the nature of the soil. We are about three or four miles from the fen district, which continues open thence to the North Sea. My list of uninjured (No. 1) may therefore be relied upon as containing only thoroughly hardy sorts. The varieties that are only partially injured are contained in list No. 2; and list No. 3 includes all those that are either killed *in toto*, are irrecoverable, or are destroyed down to the snow-line. I am sorry to include in the latter list Comtesse de Chabillant, Sénateur Vaisse, Prince Camille de Rohan, Le Rhone, Rushton Radclyffe, and Madame Charles Verdier, which must be placed here amongst the most delicate. I lost plants of the two latter varieties also from frost during the winter of 1865-6, although they were then protected by a slight covering of brakes. This year my plants were entirely exposed, and all were on the Manetti (I hope yet to see the Rev. W. F. Radclyffe rose-father to a better rose, English bred and with a better name). Céline Forestier, which has been so beautiful with me during the past two seasons, has suffered much, the wood being even blacker than that of Cloth-of-Gold. Nearly every unprotected plant of Devonensis is killed; on the other hand, John Hopper is A. 1, and Madame Rivers, Madame Vidot, Prince Léon, and Madame Furtado, four roses which I have hitherto looked upon as amongst the most tender, have stood the cold fairly without any protection. My observations have been taken (except as to the varieties of the past year) in most cases from several plants of each variety, and in many instances I am confirmed by results in another garden somewhat differently situated. I find that, as a rule, the old wood and old plants especially have suffered most, and that dormant buds have weathered best. Those of the race of General Jacqueminot appear particularly impatient of frost. The lists are long, but a perusal may save some trouble and inconvenience to amateurs, and perhaps some annoyance to growers for sale, if they will discontinue (as I intend to do) to plant and propagate even those varieties only in lists Nos. 2 and 3, the flowers of which are not beyond mediocrity, and those that are worthy of propagation on account of their beauty can in future

receive some slight protection, a course which cannot be resorted to in many gardens with respect to all sorts indiscriminately.

LIST No. 1.—ROSES UNINJURED.

Hybrid Perpetuals.	Hybrid Perpetuals.	Hybrid Perpetuals.
John Hopper	Marguerite de St. Amand	Beaufranc
La Ville de St. Denis	Comtesse de Paris	Duc d'Anjou
Madame Knorr	Semiramis	La Gloireuse
Caroline de Sansal	Jean Chérpin	Catherine Guillot
Victor Verdier	Auguste Rivière	Marguerite Appert
Jean Gonjon	Baron de Rothschild	La Tour de Crony
Charles Lafebvre	Madame Fillion	La Tour d'Anvergne
Madame Rivers	Hippolyte Flandrin	Alphonse Karr
Rev. H. Dombain	Madame Elise Vilmorin	Maréchal Forey
Madame Victor Verdier	Charles Wood	Reine de Castille
Triomphe de Paris	King's Acre	Madame Domage
Alpaide de Rotalier	Deuil de Prince Albert	Triomphe de l'Exposition
Madame André Leroy	Dr. Andry	
Princess Mary of Cambridge	Souvenir d'une Mère	Other Varieties.
Duchesse de Medina	Maréchal Souchet	Maréchal Niel
Cosli	Princess of Wales	Gloire de Dijon
Bertha Levôque	Belle de Printemps	Charles Lawson
Prudence Besson	President Lincoln	

LIST No. 2.—ROSES PARTIALLY INJURED.

Hybrid Perpetuals.	Hybrid Perpetuals.	Hybrid Perpetuals.
Wm. Griffiths	Virginal	Mademoiselle Marguerite Dombain
Baron Prevost	Géant des Batailles	Duc de Wellington
Madame Vidot	Sour des Anges	General d'Hautpoul

Gustave Rosseau	George Prince	La Quintinie
Sénéateur Favre	Leopold I.	

CHARLES LAXTON, Stamford, in "Gardener's Chronicle."

THE HISTORY OF THE POTATO.—The potato is still found on the western slopes of the Andes, the tubers, however, being no bigger than the common filbert. It was first brought from America to Ireland, where it was cultivated in 1586; but it is said to have been introduced into Spain and Portugal even before this date. From Ireland it found its way to the low countries, and to Germany, and from Spain it reached Italy and France. It is an object of cultivation in Asiatic countries only where Europeans have colonised or settled, and there chiefly for their consumption, and only since the beginning of the present century. It is successfully cultivated in Australia and New Zealand, which produce no esculent farinaceous root at all, not even the yam, the taro, or the manioc.

* In the above list are included some of the newer varieties, the powers of endurance of which I cannot thoroughly testify to, having only one plant of each.
† I have not had the means of testing any other Tea-scented varieties as they were mostly protected.

FURNISHING CONSERVATORIES.

There is scarcely any need to dilate upon the class of flowering plants best adapted to the wants of our conservatories, because those at present in popular use are perhaps as good as could be selected. Our azaleas, geraniums, both "fancy" and "show," heaths, greenhouse plants generally, and the "soft-wooded stuff," under which term is comprised calceolarias, cinerarias, &c., are all admirably adapted to fulfil our ends in this way, provided they be intermingled and tastefully arranged among such subjects as we shall presently mention. The better grown they are, the better the effect, of course. The fewer the stakes, &c., employed, the better the effect also. We once saw thirteen raspberry canes stuck round an unfortunate fuchsia; and the fuchsia, observe, is a plant that requires but one tapering stake, and which may, indeed, be grown very well and as a tolerable specimen without a stake at all when its stem becomes firm and a little established. Avoid trellises also as much as possible, though the sweet and beautiful *Rhynchospermum jasminoides* and other choice things must be grown on them. Use the best varieties of the fuchsia more than they are generally used, for if well grown into tapering and graceful plants, the fuchsia is the loveliest summer and autumn plant you can employ; its flowers are so gracefully disposed over its abundant leafage, its shape is so good, and the variety of colours so charming. Cultivate a little more variety than is generally sought, as without variety it is impossible to have interest in garden or conservatory. For the sake of a little more variety it would perhaps be well to reduce a little the azaleas, geraniums, &c., wherever the stock is solely made up of these and such as these. To advise upon the variety to be sought would not be desirable; every one should consult his own taste first, and our flower-shows and nurserymen's establishments and catalogues afford abundant opportunities to that end. But a little of such advice may not prove unacceptable with respect to the kinds we think so useful towards conservatory improvement.

Ferns are the first plants that recommend themselves in this way, and, unquestionably, a batch of comparatively free, hardy, and elegant kinds should be grown for every conservatory. A great number of ferns usually grown in the stove or warm fernery bear removal to the conservatory in summer and autumn without injury, and even with advantage, while of course all greenhouse ferns will do well, and not a few of the finer varieties admirably. We particularly allude to some of the elegantly divided varieties of the Lady fern, like *Plumosa* and others which have been introduced to cultivation of late years. They have all the grace and elegance of tropical ferns with the hardness of constitution of the commonest Britishers. Other British ferns may also be used; notably the beautiful Welsh Polypody, the charming Maidenhair, many varieties of the Lady fern (*Athyrium filix femina*) as before indicated, some of the Lastreas, and especially *L. filix mas cristata*, and the beautiful soft green oak-fern. Such may be well grown in a cold pit and removed to the conservatory at pleasure. A goodly batch of the common Maidenhair fern (*Adiantum cuneatum*) should be grown in a stove, warm vinery, or warm house of some sort; they will be useful at all times for the conservatory. Indeed, so good an aid is this plant for all sorts of arrangements of plants, that several hatches of it should be used. It is easily divided and propagated, and most useful at all times for intermingling with cut flowers. The now very popular *Isolepis gracilis* is a thing of which you can hardly have too much, its inimitable grace and refreshing green furnishing a unique effect—admirable for drooping down from the margins of stages, the edges of vases, the side of the conservatory bed, the edge of a large basket, or anything of the kind. But it is not enough to grow these and such as these; there are many plants in the country which preserve their foliage and aspect intact all the year round, and upon such stores we must draw.

The Agave *Dracæna* and *Yucca* families furnish many fine things in this way, some of them of inimitable grace, many curious and of the greatest value for intermingling with flowering plants, and particularly for furnishing effect in water when flowering plants are scarce. "To be wise," says Mr. Ruskin, "we must see and think." It is not enough to read, and therefore we advise any of our readers who are much interested in this matter to see a good collection in this way; and it is only fair to state that the best we know of in this country is in the large conservatory in Williams's Victoria Nursery, opposite the Archway Tavern, in the Highgate-road. There you may see the fine effect this class of plants produce. Some of them are variegated in the most striking manner, like *Yucca Stokesii*; others of surpassing grace, like *Dracæna lineata* and other members of the family; others, again, a rare combination of elegance and singularity, like *Beaucarnea recurvata*, which sends a slender, tapering stem from an enormous "wooden" base, so large that it nearly covers the pot, and this stem is densely furnished with leaves which, after slightly ascending, droop again and become gradually attenuated, fall several feet in the most graceful way—a slow-growing plant, and not one of those which grow as free as a cabbage, soon get too big for the house, and have to be thrown away. There is a specimen at Chatsworth with the slender stem as long as a fishing-rod and a base as big as a wigwam, but it has taken many years to come to that, and may remain a fine ornament there for ages to come.

Enough of these. There are several dozen kinds suitable for conservatory decoration. For the greater part they may be removed into the open air in summer, and utilised in the flower garden in connection with the sub-tropical movement; and then, having been well washed by the summer rains, they must be again taken into the conservatory early in autumn, where they will furnish a fine effect during the winter months. Some of the palms in a young state are also admirable for this purpose, notably the rather hardy and very graceful *New Holland Seafortia elegans* (which may also be introduced to the open air in summer), the little European date-palm, all the species of *Chamærops*, while most palms and cycads will bear the conservatory in summer. The Norfolk Island pine (*Araucaria excelsa*), which is tender in the open air in this country, is a most elegant conservatory ornament, and may also be taken out of doors in summer; while *Dacrydium Franklini* is also most graceful, being of close weeping habit. In large conservatories a few specimens of the most easily obtained tree-fern (*Dicksonia antarctica*) would be very effective, and they are now comparatively cheap, except perhaps in the case of large and well-formed specimens, which go at fancy prices. However, it is a much better as well as a much more economical plan to obtain them in a smaller and younger condition, and then grow them on, than to buy them very large. We have known them bought very large at from twenty to thirty guineas each, but they soon got too big for the house. Young specimens of the Dragon's-blood tree are very graceful from their recurved leaves.—*The Field*.

WELLS'S GROUND VINERIES.

Paper read by Mr. S. BROOM, of the Temple Gardens, at a Meeting of the Central Horticultural Society.

Now that the gardening world is every day becoming acquainted with the greater utility of these structures, I have thought a few remarks, based upon practice, might be by many appreciated.

The lady and gentleman amateur, the scientific and practical gardener, have already derived much advantage and pleasure from the use of them, and at this moment, in many gardens where horticulture is carried out upon just principles, these structures are used, advocated, and, I am pleased to say, they are recommended. Upon their first appearance in gardens, they were used exclusively for grape-growing, after which season they were carefully stowed away during the many months of the dormancy of the vine. Now they are kept in active operation during the whole year. The lady amateur finds she can manage a crop of grapes, then devote the frames to the bringing on of a few plants for late autumn and Christmas flowering; after which a few miscellaneous floricultural pots are made to occupy them, also bedding and other plants. Others, again, are being used for the protection of salading, &c.; and thus they are kept in active exercise throughout the whole of the year.

In the present month many are devoted to forcing rhubarb, and I have seen a hotbed made for them, and covered an inch thick with ashes, into which are plunged pots of Dutch bulbs, hyacinths, tulips, &c. Others, again, are used in a similar manner for the propagation of bedding stuff, and the raising of seeds of tender plants for the embellishment of the parterre. These structures are invaluable, since a lady or gentleman who does not retain the services of a regular gardener can obtain and enjoy many horticultural luxuries which are denied where only an ordinary glass-house of the original form is at hand. The scientific and practical gardener can apply these miniature houses to a thousand different uses. But a few days ago I saw a fourteen-foot length filled with hyacinths and tulips, which are intended for our great spring bulb-shows, and nothing could exceed the luxuriance and the vigour they possessed. I have likewise seen them applied to the growth of that delicate winter plant the Neapolitan violet, and beautifully well-coloured blossoms were being gathered from them, when not a vestige of flower was discernible in the old-fashioned, dark, dismal box-frame, although both were placed near each other, and were subjected to the same and equal management. The plan of arranging the ground vinery for this purpose was extremely simple, but clever, and shows what really invaluable structures these prove to be for the gardener. In the month of October last, when all the fruit had been cut from these vineries, a bed was marked out of the area of the vinery, round which common bricks were laid two deep; the bed thus formed was filled with ashes of coal, and the violets, which had previously been potted into 32-sized pots, were plunged in them. The plants were thus exposed to intense light—an agent so essential (as all gardeners are aware) to the well-being of this plant. The folding nature of these structures renders them particularly adapted for violets, too, because it is the easiest matter possible to expose the plants fully to the weather, or entirely protect them from its effects. Should the weather be mild with moisture falling, the lids or sides can be raised nearly horizontal, thus exposing the plants to air and protection from wet at one and the same time. During the inclement weather we had in the past winter, the vinery was covered with litter and thatched hurdles placed together in the shape of a span roof. This protection bid defiance to cold 9° below zero, and will henceforth afford means of protection for these unheated glass structures. During the past season I have seen some magnificent crops of grapes under them. The bunches were of a good size, the berries well swelled and above the average size, with the colouring as perfect as any that have been cut from more spacious houses, and the flavour exquisite—in fact, everything the greatest connoisseur could wish. I find many growers, elated with the success of these vineries, intend applying them to the growing of stone-fruits, such as peaches, nectarines, &c. These are to be planted out and treated precisely the same as the vines. The slates will be laid down and perforated at regular distances, so as to admit pegs wherewith to peg down and lay out the branches at regular distances. The roots being free to act on the outside, as in the case of vines, no watering is necessary, as when these fruits are grown in pots upon the orchid-house principle. Moreover, the moisture emanating from the slates, with which the wood and foliage are in contact, prevents red spider, thrip, and other insect pests from generating. The wood is short-jointed, vigorous, and ripens so early that no difficulty exists in the production of fruit-buds. This process, under these circumstances, is more certain than by any other means. The free admission of heat, light, and air is the chief and great characteristic of this invaluable invention, by which all the agents are secured, and upon which the highest principles of horticulture are dependent.

I find the best method of cultivating fruits under these vineries is as follows: At one end of the vinery a hole, two feet square and about two feet deep, is dug and filled with a compost of good loam, rotten dung, and a little road-sand. These should be well incorporated together, previously throwing in about a peck and a half of bones, merely bruised, to afford drainage to the mass, also to feed the vines during hot weather or when the heat is so great as to rob the plant of its natural moisture. The bones will likewise absorb the fluids passing down to them the more readily by being bruised. All being thus prepared, the vine is turned out about the middle of March, providing the weather is open and mild, the cane being introduced and pegged down. Air should be admitted about 10 o'clock a.m. by raising slightly the lights; this, with the additional air from the bottom of the frames, will serve to check the vines from making too quick and premature a growth before the season is sufficiently forward to assist and facilitate the young growth. The cases should be closed again about 2 p.m., if possible, securing a little atmospheric warmth. The vines should be at this period slightly syringed. The moisture will aid the expansion of the bark and the bursting of the young buds and leaves. This process should be continued until the flowers are expanded, when syringing must be entirely suspended, and air admitted upon every opportunity. As soon as the flowers are set, I find moisture applied in the form of vapour highly beneficial: this can be obtained by pouring tepid water upon the slates. Atmospheric warmth is generated throughout the day, and causes the moisture to evaporate, thus charging the internal air with an agent highly beneficial. As soon as the grapes have got to the size of sweet peas the bunches should be thinned, taking out all ill-shaped and deformed berries, also all those which are in immediate contact with others, taking care not to take out all the interior berries, or the bunches will be loose and ill-shaped. At this period the structures should be kept close,

and as much warmth secured as possible, as the critical time of stoning will have arrived, and a check at this period would prove highly injurious. As soon as colouring commences, as much air as possible should be admitted consistent with safety from chilling; and the vinery must be closed sufficiently early to secure, as before stated, as much natural warmth as possible. If this course is pursued, I feel confident every success will attend the operator, and will repay him for the pains he may bestow. The weight and quality of the fruit will equal, if not surpass, that which is grown in extensive vine-houses.

I have, during the past winter, seen a very happy adaptation of these useful structures to horticulture, and applied to a very excellent use. One of the fourteen-foot large sized vineries was selected; a site facing south was arranged, and a pit dug 3 feet deep, the sides bricked with 4½ work. Two feet above the ground-level, upon the brickwork, was laid a wooden plate, and to this the vinery was fixed, being screwed down at the four corners of each division. The pit was then filled with coconut fibre refuse, and such plants as fuchsias, geraniums, bulbs, &c., &c., placed therein. These when introduced grew with great luxuriance, and in other cases, where they were well covered with litter and the thatched hurdles, resisted the intense frosts we experienced during the month of January last. The same vinery pit, at this moment, is filled with fermenting material, and rhubarb and sea-kale and salading are being cut therefrom, with cucumbers climbing along the roof and looking as luxuriant as upon ridges in summer; while Dutch bulbs are being brought out weekly for the drawing-room, &c. This plan is merely an enlarged idea of what was before exemplified, and serves to prove how invaluable they are to the horticulturalist, and to what a variety of uses Wells's Ground Vineries can be applied. I have no hesitation in saying that, when more generally in the hands of gardeners and nurserymen, a greater demand will be made for them; their elegance of design, lightness of construction, portability, and durability, will ere long secure to them great popularity; and no garden, whether the manse, villa, or baronial, will be without them; and the day is not far distant when wonders in horticulture will be achieved by the use of Wells' Patent Ground Vineries.

SEEDLING AURICULAS.

The raising of seedling Auriculas having become a favourite pursuit, the following instructions may be of service to those persons who are desirous of transmitting their names to posterity as the originators of a few first-class flowers; but let me here advise the raisers of seedlings not to be discouraged should their first efforts prove a failure. The seed of the Auricula, even when saved from the very choicest flowers, is very uncertain as to its produce. I consider myself very fortunate when I get a first class show flower from a thousand plants.

The most suitable time to sow the seed is about the beginning of February, and the best site for the pan is the front shelf of a greenhouse. Persons who may not have this convenience, may place the pan in a window of a fire room, looking to the south, as frost must not be allowed to act upon it. The pan or box will require to be either 3 or 4 inches deep, and of a size proportionate to the quantity of seed to be sown. Fill the pan with the usual compost to within ½ an inch of the top, and press the surface perfectly level. Then water with tepid water, applied by means of a fine rose or a soft brush; when the latter is used, shake out the water and strike the bristles with the hand, so that the water may fall like fine dew on the surface of the soil. Should there be any inequalities on the surface after watering, fill up the cavities, and have it perfectly level. Sow the seed carefully, not too closely, and merely cover it with some of the compost finely sifted. When the seed is sown, water again as above directed, and place a piece of glass over the top of the pan. This obviates the necessity of watering often, keeps off dust, and accelerates the vegetation of the seed. Never allow the soil in the seed-pan to become dry.

In about a month or six weeks at farthest the young seedlings will begin to come up. They will then require to be looked over daily, for when they come up, they almost invariably throw themselves out of the soil with a jerk, and must be replanted immediately, otherwise they would be lost. This can be done easily with the point of a penknife. Make a small cleft in the soil, lift the young plant with the point of the knife, and replant it root end downwards, and close the soil about the neck of it.

After the plants are up, give air for a few hours, when the sun is upon them. In April remove the pan into the shade, where they will get the morning sun till about ten o'clock. Whenever the young plants have six leaves, shift them into pans or pots, and when they again get crowded shift again.

When they have attained to blooming size, pot three plants round the edge of a 5-inch pot. From long experience I have found this the best method of treating them. Then as they bloom in the spring, all the useless sorts must be taken out of the pots; these will do to plant in the borders. Those that promise well are to be repotted, in pots of a suitable size; but they must not be over-potted, and when they bloom the following year, and prove to be really good stage flowers, they must be taken care of. Too often the raiser is disappointed in the quality of seedlings that he anticipates will prove to be first-rate. Often they degenerate and turn coarse, after blooming extra fine in the first years of their existence. No dependence can be placed on an autumn bloom. A spring bloom is the only sure test. I have now been raising these flowers for the last forty-six years, and the information contained in this article is the result thereof.

I think I have tried every sort of experiment in the way of fertilizing, but the most successful was fertilizing Chapman's Maria with the pollen of his Sophia. These flowers are both beautiful violets. From this seed I got what have proved, after years of blooming, five first-class varieties—one of them a self, and I think about the finest I ever saw; but after growing it for ten years I have not yet had any increase from it. The others are all very beautiful violet-ground sorts, causing me to rejoice at having attained the object at which I was aiming. It is curious that among the seedlings raised from this fine seed there were some Primulas, although I have none of either them or Alpines near me, for fear of spoiling the seed.

GEORGE LIGHTBODY, Falkirk, in "Gardener's Chronicle."

In the time of Sir John Macpherson's Government, most of his staff consisted of Scotch gentlemen whose names began with Mac. One of the aides-de-camp used to call the Government-house *Atmack's*. "For," said he, "if you stand in the middle of the court and call *Mac*, you will have a head popped out of every window."

THE LOIS WEEDON HUSBANDRY.

Without entering into any examination of what Jothro Tull really did teach, the points wherein Mr. Smith differed from, or rather went beyond, his great instructor may be briefly stated. At a time when tillage implements were of a rude description, and arable husbandry was almost entirely unmanorial, Tull completely established three propositions—first, that inter-culture amongst growing crops is a necessary operation in well-conducted farming; second, that adequate mechanical tillage is an economical substitute for manure; and third, that thorough tillage is also competent, with or without the aid of manure, to secure the profitable growth of any given species of cultivated plant, year after year on the same ground. At first derided, at last universally appropriated, Tull's maxims have become the foundation of modern practice in the culture of all roots, of many green crops, and certain kinds of grain. Tull conceived that the rootlets of plants "depastured" (as he called it) upon the superficies of minute particles of earth, and that, therefore, to feed a crop with all the nourishment it needs, an abundance of this pasture must be provided by pulverization, effected partly by mechanical tillage, partly by air and moisture introduced by this means into the soil. And farmers now are fully alive to the stimulating power of ploughing and stirring the ground between rows of plants sown in rows wide apart for this purpose. But the soundness of the theory is still disbelieved in, and the practice repudiated in relation to cereals—the drilling of wheat and oats and barley being adopted mainly as a facility for cleaning the crop of "annual" weeds. Tull himself had grown small but remunerative wheat crops year after year on the same land, and without manure, disproving the supposed necessity for what is called the "rotation" or alternation of different crops; and Mr. Smith devoted his leisure to the delightful employment of testing Tull's principle to the uttermost. If that mingled mass of the oxides or rusts of certain metals which we call "earth" really held an inexhaustible store of plant-food within it, or had the power of acquiring this fertility in proportion to its divisional treatment by tillage, there could be no valid reason for limiting mechanical operations, as Tull did, to the few inches of ground called the "staple;" for if sufficient pabulum for a prolific wheat crop cannot be procured in this thin stratum, why not search deeper with our tools, and try if successive crops will not find pasture enough in a comminuted subsoil? Mr. Smith dug his way inductively into the exhaustless fecundity of his clay subsoil. The details of his husbandry would make too long a story for this paper; but in general his plan was this—he sowed his wheat in stripes of three rows each, the rows being ten inches apart, and left between the stripes bare intervals of forty inches breadth, which he followed by spade, fork, and horse-hoe. The next year's wheat stripes were sown upon these intervals, and the stripes of stubble dug in for fallow spaces. Absolutely, each crop stood upon stripes of land that had been bare-fallowed throughout the previous year; but so extraordinary was the effect of digging and horse-hoeing the fallow intervals for next year in close proximity to this year's growing plants, that the area occupied by the wheat stripes—that is, half the surface of the field—was found to yield in measured produce of grain fully double what the same area would yield if after a year's bare fallow the wheat were sown "together," or in one whole plot, without interlined stripes of fallow; that is, each row gave an increase of 100 per cent. from the mere circumstance of being what a printer would call "spaced out." Mr. Smith's maximum crop gave 40 bushels per acre over the whole field; or, to state the fact in another way, half the field (in the form of 30-inch wide stripes) bore a crop of 80 bushels per acre; while the other half of the field (in 30-inch-wide tilling stripes) was dead fallowed for the next year's crop. Mr. Smith, however, preferred to speak of his wheat as grown annually without intermission on the whole field. The average produce of the first eight years, beginning with the harvest of 1847, was fully 34 bushels per acre—the whole area within the boundaries of the field being included in the measurement; for the next four years (1853-1858) the yield averaged 38½ bushels per acre; and in another equal period (1859-1862) the average was 33 bushels per acre. The crop of 1863 thrashed no less than 40 bushels per acre—which had been equalled before both in 1855 and 1858; and the last harvest of which any account has been published (1864) produced 32 bushels per acre, this being the eighteenth wheat crop in yearly succession. The average yield of the last ten years was 35½ bushels per acre, which is just 1½ bushels in advance of the average for the previous eight years. As to quality, Mr. Smith usually made the price of the best red wheat in his market; and the quality of his latter samples surpassed that of the earlier. No manure, animal, vegetable, or mineral, was ever applied to the land during all this long course of incessant corn-bearing; mechanical tillage did it all. Indeed, the length and bulk of the reedy stems and broad flags of the "straw," and the weight of the huge heavily loaded "ears," would not bear any forcing by manure; that is, heavier crops would have "gone down" flat and failed to ripen properly. This was the Lois Weedon experience with corn, which is thought an "exhausting" or manure-loving crop; whereas, roots and green crops, which are looked upon as acquisitive or fertilising crops, would not respond to Mr. Smith's treatment unless he plentifully pampered them with manure. The effect upon the land of eighteen years' wheat growing without manure was that a good brown heavy loam, equally good and fertile to a depth of 1½ to nearly 2 feet—for to this extent did the spades penetrate, accomplishing a perfect "inversion" of top and bottom "spits"—took the place of the original 5-inch staple and the 13 to 18 inches of raw clay subsoil which used to lie under it. So far from "exhaustion" coming in view, the land became not only ameliorated, but greatly enhanced in value. Mr. Smith's annual profit upon his outlay was also large; though he sold the grain at low prices, and set a moderate valuation upon his straw, which was all carried away and applied as manure to other land.

It is remarkable that the success of the Lois Weedon wheat-growing has never thoroughly commanded the sympathy of practical men. If Mr. Smith had happened to win his great results by the use of horse-drawn instead of hand-worked implements, his practice would probably have found numbers of eager imitators. But it will be a lasting reproach to British husbandmen if they allow the whole experiment to die, merely because hands are not numerous enough, over thousands of farms, for a slavish copy of Mr. Smith's manipulation. The magic power lies in the tillage, not in the tools; and it is a poor compliment to modern agricultural art to think that it cannot adapt the Lois Weedon system to implements worked by animal or steam-power traction. In fact, the "Journal of the Royal Agricultural Society" for 1855 does contain a paper describing four years' experience of the stripe-cultivation of wheat, in which the plough, subsoiler, grubber, and horse-hoe, the harrow, drill, and roller, were the implements employed. The whole process is explained, every item of outlay stated, the annual profit fully proved, and a system suggested for introducing with advantage two or more

successive white-straw crops into a rotation. The writer, Mr. John Algenon Clarke, concludes his essay in these words: "I know that it is difficult to move the mind of a practical man out of its habit of settling things from general considerations. I shall be told that an extension of wheat culture is not advisable, because roots, clover, and cattle crops have of late years answered better. But what can the wheat crops that don't pay possibly have to do with my wheat crops which will pay? The entire case rests upon the low cost of production by my method, in comparison with the cost of a wheat crop in ordinary farming. I raise two good wheat crops in succession for £5 10s. per acre each (every source of outlay included); and at the same time, and for the self-same money, I am fallowing and cleansing the ground in readiness for roots or other of the third year's crops. Can any other system show an economy of expenditure like this?"

We believe that a few attempts at the spade culture of annual crops of wheat have been made in different parts of the kingdom, some successfully, others not. We have seen in a traveller's volume an account of a "Lois Weedon" experiment in Normandy; and in the spring of 1866 Mr. Smith received a number of earnest applications for information from persons in Canada. We may hope, therefore, that whatever of sound principle was demonstrated over and over again in his protracted and astonishing experience will not be lost to the world; that future wheat fields will bear in their beautiful triple lines the indelible mementoes of his thoughtful toil; and that thus, as well as in the fruits of a good ministry among the villagers whom he loved, his "works" will long "follow him."

"Field and Homestead," Daily Telegraph, Feb. 28th.

CULTIVATION OF DWARF APPLE TREES.

Dwarf trees are most suitable for small gardens; they may be planted six or seven feet apart every way, trained like bushes, and nothing should be planted over or near their roots. The bearing branches should spring from one central upright stem, the undermost at about six inches from the ground if possible, as the nearer the trees are kept to the ground the better. The branches should not interfere with one another, and be so far apart as to allow light and air to pass freely amongst them. The form will be somewhat of a low, broad pyramid, not open or basin-shaped, as sometimes recommended, but with every part of the space of the tree properly filled up, and the height never allowed to exceed five feet. Young trees should not be cut back at the time of first planting, any cutting which may be required to put them into shape being reserved for the autumn pruning. In following years the summer shoots may be pinched or topped, beginning with those of the upper part of the tree towards the end of August; leaving those at the sides and under part till two or three weeks later: this assists the developing and maturing of the fruit buds, and the ripening and colouring of the fruit. As soon as the leaf falls the trees may be pruned: all the wood shoots not required for main branches should be removed pretty closely, and the ends of the leading stems cut back to from three to six eyes, according to the strength of growth and habit of the variety. If the cutting be too long, some of the buds remain dormant, and the branch becomes so far bare; if the cutting be too short, the eyes become wood shoots instead of fruit buds. When the growth is too luxuriant it may be checked, either by opening a trench round about the trees at a little distance from the main stem, and cutting rambling roots, or by lifting them entirely out of the ground, cutting back the strongest roots, and replanting. Each of these operations requires to be done with some judgment, for if the cutting is made too close, the tree will receive too great a check; then, again, where the soil is light from which a tree is lifted, the roots will, most likely, come clean out without any soil adhering to them, and as this of itself will give a considerable check, the less root-pruning will be required. In adhesive soils, where trees can be lifted with a good deal of earth attached to them, the operation of lifting and replanting is more easy and safe to persons of little experience. Whenever a tree is lifted its roots should be gently treated, not torn, but fairly raised from the ground.—REV. R. O. BROOMFIELD, in *Stuart and Mein's Fruit Tree Catalogue*.

COCKROACHES.—While cockroaches partake largely of the common articles of diet in the ship's stores, they also rather like books, clothes, boots, soap, and corks. They are also partial to lucifer-matches, and consider the edges of razors and amputating knives delicate eating. As to drink, these animals exhibit the same impartiality. Probably they do prefer wines and spirits, but they can nevertheless drink beer with relish, and even suit themselves to circumstances and imbibe water, either pure or mixed with soap; and if they cannot obtain wine, they find in ink a very good substitute. Cockroaches I should think were by no means exempt from the numerous ills that flesh is heir to, and must at times, like human epicures and gourmards, suffer dreadfully from rheums and dyspepsia; for to what else can I attribute their extreme partiality for medicine? "Every man his own doctor" seems to be their motto; and they appear to attach no other meaning to the word "surgeon" than simply something to eat. I speak by experience. As to physic, nothing seems to come wrong to them. If patients on shore were only half as fond of pills and draughts, I, for one, should never go to sea. As to powders, they invariably roll themselves bodily in them; and tinctures they sip all day long. Blistering plaster seems a patent nostrum, which they take internally, for they managed to use up two ounces of mine in as many weeks, and I have no doubt it warmed their insides. I one night left a dozen blue pills carelessly exposed on my little table; soon after I had turned in, I observed the box surrounded by them, and being too lazy to get up, I had to submit to see my pills walked off within a very few minutes by a dozen 'roaches, each one carrying a pill. I politely informed them that there was more than a dose for an adult cockroach in each of those pills, but I rather think they did not heed the caution, for next morning the deck of my little cabin was strewn with the dead and dying, some exhibiting all the symptoms of an advanced stage of mercurial salivation, and some still swallowing little morsels of pill, no doubt on the principle of *similia similibus curantur*, from which I argue that cockroaches are homœopaths, although had they adopted the other homœopathic theory first, and taken infinitesimal doses, they would then have experienced the full benefit of that noble doctrine, and the medicine while doing them no good, would have done them just as little harm.—*Chambers's Journal*.

A certain method of keeping eggs from spoiling.—Eat them while they're fresh.

ROSES AND ROSES.—No. III.

The last I saw of O P Q was enough to make the most sanguine of the hopeful class despair of his taking a First this season. He seems bent on taking nothing but vexation, and if now he sings at all, it should be the sad song of Kirke White, the blighted genius :

“Come, Disappointment, come.”

You will understand that I have but small hopes of his success, for I found him pruning his roses with a knife and fork, and he would have ruined them had I not R S T'd his hand. When I say “knife and fork,” I use a figure of speech for that sort of pruning which consists in hacking things about without any proper knowledge of their requirements, or any consideration of the way in which trees grow after pruning. Yes, he was simply cutting them by the rule of guess-work, and appeared to think that there was a proper way to prune every particular rose, and, therefore, to make a study of the art of pruning would be to waste a lifetime, and then not learn it all ; and so the way out of the difficulty was to cut the Gordian knot, and become the exponent of a slashing universalism. But I learn something from such examples, and I learn now that we “gentlemen writers” are very much to blame for putting our teachings into ambiguous language, and actually making traps for the unwary in the books and papers we write. Take this subject of rose-pruning, and how simple it is in reality, yet how few amateurs know anything about it after all their searching ! There is first the question of the Time, and secondly the question of the Manner.

Now, as to the time, the rose itself will speak. Every variety that persists in growing until stopped by hard frost, and that begins to grow again the moment the temperature rises above the level of freezing, is by its precocity always in danger during the treacherous English spring. It grows to-day that it may be killed to-morrow, and the climate appears to be always ready to assist it in the gratification of this base ambition. What shall we do with such roses—shall we prune them early or late ? Now, before we answer this question, let us consider in what respect pruning influences trees. We find the first and strongest growth usually takes place at the extreme points of branches, and while trees are in good health the finest shoots are formed in their highest parts. There is evidently a power in operation tending always to drive the sap upwards. Observe now the roses that have not been pruned, and at the extreme ends of the longest branches there are little tufts of green leaves, and all the next adjacent buds are starting freely. Now to bring the trees into shape these growing buds must be removed, and the moment we prune, say the third part of a shoot away, the buds at the base of the shoot will in the order of growing take the place of the buds that were removed by pruning. So long as they are unpruned the topmost buds have the lion's share of the sap ; when pruning is accomplished, the sap is pretty evenly distributed amongst the buds that remain, and these grow almost immediately after pruning is performed, in consequence, we may say, that, as the sap is moving, *it must go somewhere*. Now the time for pruning must be regulated by a consideration of these facts. This is a treacherous climate, and the precocity of certain kinds of roses exposes them to the destructive influences of our late spring frosts ; therefore we must not by early pruning force the growth of the buds on the ripe hard wood that we intend to keep, but let the growth proceed as it pleases until the season is so far advanced that the roses are out of danger, and then we may prune them. Compare now at this moment unpruned plants of the common Cabbage Rose with some of the Hybrid Perpetuals. The buds of the cabbage roses are so little swollen that we can only discover them by their accompanying red rings, but the perpetuals are bristling with new growth. We may therefore prune the cabbage roses, for they are in no haste to grow ; but it will be safer to wait till the end of March, or even the first week in April, to prune the perpetuals, so as to reserve to the latest possible moment unhurt those buds from which we are to obtain our roses. In fact, sorts like the Cabbage, the French, the Alba, and the Damask roses may be pruned any time during the winter, for they will not begin to grow until the season is sufficiently advanced to put them out of danger ; but we must leave untouched till quite the end of this month all the excitable kinds, that in the event of frost it may spend its rage on the tops of the shoots where the sap is now most active, and kill if it pleases the callow shoots that are ultimately to fall before the pruning knife.

We come now to the manner ; and I beg O P Q and all else to observe that the prevailing manner of pruning roses is too severe. I am an advocate for extension here as in the vinery. I saw some Alba roses on a steep bank at Cyfarthfa Castle last year ; they were on legs a foot long, from whence sprang great round diffuse heads about four or five feet high, and four or five feet through, these heads dotted all over with white roses, glorious to behold. Some of the fraternity would like a chance to cut them down to within a foot of the work, and convert these huge, these magnificent bushes into dumpy doll's-garden trees. You will see in No. I. what my

ideas are about pruning for exhibition, and mayhap I may yet speak again on that subject ; but here let me say that the one object of the man who prunes roses with a view to improve the beauty of his garden, should be to promote the formation of large handsome trees.

Then, as to the manner of it, it may be held as a rule that the more robust the growth, the more sparing should be the use of the knife. The long whip-like shoots of *Gloire de Dijon*, *Jaune Desprez*, *Maréchal Niel*, and *Lamarque*, should only be a little shortened, so as to cut away the mere soft point of the least perfectly ripened wood, in which case the upper two-thirds length of those long shoots will bristle with flowers, presenting the grandest appearance possible in the rose-garden. But if, alarmed at their enormous length, we cut two-thirds of the length of such rods away, the remaining third will probably not afford a single bloom ; so lay the rule to heart, my dear O P Q, and all else who pretend to doat on the Queen of Flowers. Apply the rule, and see how well it holds, with scarcely an exception. The Provence, Damask, French, and Alba are all moderate growers, and may be cut back to within two or three inches of the old wood. Suppose I take the knife in the right hand, and a stout branch of cabbage rose in the left. I see at a glance which are the shoots that were made last year : some of them perhaps have still the remains of flowers, perhaps pods of seeds hanging to them. I cut those last year's shoots away all but the last or lowest three, four, or five buds, and any branches that cross through the centre of the tree I cut clean out from the base, and any long thin shoots that have no strength but extravagant elongations, I cut back to one bud, in the hope that the one bud may produce a strong shoot in the forthcoming season. But when I come, or when you come, to the robust Perpetuals, Bourbons, and Noisettes, we must not prune so close ; we must first cut with a view to form a large, bold, regular head, and next with a view to get rid of thin spray and branches badly placed ; and if there is a gap in any part of the tree where a strong shoot would be an advantage, we must cut back one or two of the twiggy branches next it on either side to one or two buds each, and the probability is that those buds will break forth in vigorous growth, and fill up the gap as required. I repeat that, as a rule, roses are too severely pruned, and the result is two great defects of the rose garden—the trees have no beauty and produce but few flowers. Lay it to heart, friends, and when the time to prune arrives, see how little, not how much, you can cut away, and yet do justice to the trees in every particular.

Lastly, what do you say about not pruning at all ? I can suggest to you a possible sensation. Lay out a border four feet wide ; it may be of any length you please, but must be in an open spot, exposed to all the winds of heaven, without shelter from sun and wind. It will be well if it is within view of the principal windows, with a background of evergreens a few yards in the rear. If it is good loam or clay, have it dug two and a half feet deep, and heavily manured with fat half-rotten dung, and leave it as rough as possible till the first week in May. Then turn out from pots own-root plants of a few of the most showy and robust hybrid perpetuals—say, for a good dozen, the following : *Jules Margottin*, *Victor Verdier*, *Baronne Adolphe de Rothschild*, *John Hopper*, *Sénéateur Vaisse*, *Louise Darzens*, *Madame Alfred de Rougemont*, *Comtesse de Chabillant*, *Anna de Diesbach*, *Caroline de Sansal*, *Madame Victor Verdier*, *Xavier Olibo*. They must be four feet apart, and the bed must never be planted with anything else except mere surface-rooting plants, such as stocks, asters, and other small subjects. Indeed, this bed would serve admirably for a display of the smaller kinds of hardy herbaceous plants, such as the tutted campanulas, and also of annuals of small growth. In the March following prune all to one foot, the next year prune all to three feet, the next year prune all to five feet, and the next year do not prune at all, but advertise a grand rose-show, and charge for admission as much as you can get. But I had almost forgotten the life of the recipe, the seasoning to this grand dish. Every year, as soon as the pruning is done, cover the ground with about half an inch depth (not more) of wood-ashes and guano, neither of which have been previously exposed to the weather. I saw some men at work in O P Q's garden carting loppings and prunings somewhere to be burnt. If the burning has not yet been done, I advise him to wait for dry weather, then burn, and at once store the ashes in a dry place, as the first instalment towards the sensation. As for the rest, his soil is loam in which trees grow superbly, and he can afford the labour and the manure for the rest, as he can also the few shillings that will suffice to buy the roses. As a last word for the present, I say abjure the knife and fork system, and don't be in a hurry to prune growing roses. *Melius est cavere semper quam pati semel.*

S. H.

A gigantic work is on the tapis. It is nothing less than the drying up of a great part of the Zuyder Zee. The extent of the land proposed to be reclaimed is 380,000 acres, and the cost of the work is set down at £10,650,000.

NOTES ON BEDDING EFFECTS AND BEDDING PLANTS.

As the time is coming on when all who have gardens will be thinking about how they will arrange and decorate them this season, I think our time will be well spent if the matter is thought over a bit in advance. Let us see if we cannot do better than we have done before. We will first go to the plan that has been adopted of massing plants of different colours together, to have what is generally called the best effect, as in the grouping system in the gardens of Kew, Battersea, Hampton Court, and the Crystal Palace, as well as of other gardens on a much smaller scale. But has it never struck you, gentle reader, as it has me often, that we really bestow much labour and time on what, after all, is but a transitory scene, or, in other words, we are planting and potting, and otherwise preparing plants for nine months, to enjoy but three months of their beauty; for bedding plants cannot be said to have very much show in them before the middle of June (and you must have strong plants to get it then), and after the middle of September their beauty and gaiety is all but gone, or at any rate fast going, and that is just three months? And a very little later in the season, up we pull the plants, or a portion of them, to pot, to supply us with cuttings and so forth, when needed, for the coming season; and during all the rest of the year our beds are a blank (or, at any rate, where the bedding system is carried out), unless we plant bulbs for spring decoration; and in nine cases out of ten this generally turns out different from what we intended, or at least expected, for it is generally managed so, viz., hyacinths or tulips edged with crocus or snowdrops, and as a matter of course the crocus and snowdrops bloom first, and that is just like looking at a frame without the picture, and *vice versa*.

There used to be a time (and I look back to it with much pleasure), when I was young at gardening, that the flower garden was at all times attractive and somewhat gay, and with hardy herbaceous plants, that gave us no trouble whatever, except when we dug up the borders, and that was just to put the spade through them to divide all clumps that were becoming too large. There were our immense clumps of *Phloxes* of all colours, "and so sweet," mixed with the herbaceous *Lobelias*, with their lovely spikes of scarlet, blue, crimson, white, and damson, and other colours: these, with a large clump of *Tritoma* in the middle, formed the centre part of a large round bed. Then came some *Pentstemons*—and how lovely these were, so bright and lasting! *Antirrhinums* of all colours; *Campanulas*—and of those we had shades of blue and white, both double and single, and short and tall; *Perennial Lupins* of many sorts and all heights, with here and there a clump of *Ribbon Grass* (*Phalaris arundinacea*) mixed up with the flowers to add grace to their richness. Then, for the front of the bed, we had our *Carnations* and *Pinks* and *Pansies*, with *Aubrietias*, *Arabis*, *Alyssum*, *Daisy*, *Hepatica*, *Iberis*, and a host of plants in this way—and these were all hardy, mind you; and in the summer we mixed up with them our *German Asters*, *Stocks*, and a certain quantity of various *Geraniums*, *Verbenas*, *Calceolarias*, &c. Now by following this plan of bedding-out, we were seldom without bloom of some sort; for at Christmas, and long after, we had the *White Hellebore*, then came our clumps of *Snowdrops* and *Crocuses*, in company with *Violets*, *Hepaticas*, *White Alyssum*, and other plants. Then the *Pansies* came on, with the double and single *Auriculas*, *Polyanthus*, and *Primulas*; and in May we had lots of things to look gay, including the *Lily of the Valley*, *Dielytra spectabilis*, and so forth; and then through the summer and autumn the garden was always looking cheerful with something right up to November, the last to bloom excepting *Chrysanthemums* being *Antirrhinums*, *Verbena Venosa*, *Asters*, *Mignonette*, *Tritomas*, and other plants.

I say again, I see no reason why all these beautiful plants should be quite put on one side, to give place entirely to summer bedding plants. Why not grow a selection of each, and secure bloom in our gardens a greater portion of the year, instead of, as now, having a blaze like a sky-rocket for a short time, and then so soon fading away, leaving nothing but the sky-rocket case and stick? And I am sure, if a portion of the good taste displayed in arranging the bedding-out plants were brought to bear on herbaceous plants, we should not be wanting a good display. But you will perhaps say, "We are wanting in colours in herbaceous plants to make the display that we get in bedding plants." Are we, indeed? Let's contrast a few plants together, and see how we shall get on. Now for **YELLOWS**, the *Calceolaria* is about the main prop for your bedding plants. Just so; but I have seen clumps of *Ænothera* that would place all such in the shade. It is true it does not open on wet days, and it would be as well if *Calceolarias* did not; for I don't know of any plant that has such a water-logged appearance in wet weather, leaving out the shattered aspect they present the morning after a thunder-storm. Then for **BLUES**, *Lobelias* we all like, and always shall, and *Purple King Verbena* ditto, and there is not much else in bedding plants of this colour. But suppose we introduce some

beautiful *Delphiniums* and *Plumbagos* and *Herbaceous Lobelias*, and vary our edging with some *Gentianellas*. These last are so beautiful that I wonder how it is we get along without them. I saw an edging of them around the flower garden at Abbotsford, the seat of the immortal Scott, and every flower was as large as a pigeon's egg, and the colour a heavenly blue. And for **SCARLET** and **CRIMSON**, I must confess to have seen a bed of *Dianthus Dunnettii* that shut out all the pretensions of *Geraniums*. Then we have the *Lobelia fulgens*, and the *Gladioli*, and a lot of other plants. And for mixed colours, there are the *Veronicas*, the *Hesperis* or *Rocket*, the beautiful *Double Pyrethrums*, of all colours; and for edging, the *Gnaphalium*, *Aubrietia Campbellii*, and many others equally beautiful. Now, what do you say after all this chat about bedding-out plants? Don't you think it is time we turned over a fresh page in our bedding-out system? Suppose we try half herbaceous plants in our coming summer decorations? We shall be sure to come to it at last, and the longer it is left the more difficulty and expense there will be in forming a collection of good subjects. At present the cost of those I have named will be no more than for strong bedding stuff, and in some cases much less even than that. So, good reader, I have placed the whole matter carefully before you, and there is plenty of time for you to reflect before bedding-out time in May. Or should you decide on giving a few hardy plants a trial, you can begin at once. No fear of the frosty mornings for these; and another advantage is, there they will be year after year, and increasing in size and beauty.

JOHN BURLEY, F.R.H.S., &c.

Albert Nurseries, Pembridge Place, Bayswater, W.

THE CYCLAMEN.

If those people who profess to be so anxious to retain the common or vulgar names of plants, in preference to the botanical or scientific names, which are derived from or founded upon some peculiarity in the manner of growth, or else in the shape or colour of the flowers, or perhaps the whole combined, would take the trouble of inquiring into the subject, and ascertaining what really are the common names of the generality of the plants that they are so desirous of retaining, I strongly doubt whether they would be so loud in their protestations in favour of the retention of them. For instance, who would willingly change the name of this very elegant and charming little plant for its anything but elegant name of "Sowbread"? The fact of the wild boars of Sicily being partial to the varieties indigenous to that island would, I should fancy, be but a poor compensation, and do very little towards reconciling them to what I consider in my own mind to be a not very agreeable change. But I am running from my subject, for I certainly do not intend entering into a discussion or controversy upon the question of plant nomenclature, which would in all probability be of very little service to any one, and at the same time occupy very valuable space that can undoubtedly be made available for much better purposes. It will not be necessary for me to pass a eulogy upon the merits of the *Cyclamen*, particularly *persicum*; for there cannot be two opinions about its being quite invaluable for the decoration of the conservatory through the winter and early spring months, and also, for furnishing fancy baskets and jardinettes for the drawing room through that season, nothing can equal it. It is also quite an acquisition for bouquet making, for through January and February flowers suitable for that purpose are not so very plentiful to cut at. I think this latter point to be one of the chief excellences of *persicum*.

The only way to propagate this plant readily and with certainty is by seed. I have seen in treatises upon this subject propagation by division recommended, but I question very much whether the writers have ever divided the corms with a sufficient degree of success to warrant their being able to *conscientiously* advise the following out of that practice. It is my opinion that it has been written upon supposition only, instead of being based upon actual practice. I have never known it done, and therefore I shall certainly not advocate it; besides, a careful examination of the structure of the corms has left a very strong impression upon my mind, that it must require an unusual amount of skill and dexterity in the use of the knife to be able to accomplish a division without entirely destroying them. We will now turn our attention to propagation by seed, which is decidedly the best way, and the only one which will enable a good stock to be raised quickly. The best time to sow the seed is directly it is ripe; now is also a very good time, particularly for any one who has no plants to save seed from, but has to procure it from the seedsman. The seed should be sown in a mixture of nice light rich stuff, say equal proportions of loam and leaf-mould, and a sprinkling of sand; the leaf-mould should be sifted through a medium fine sieve, for the young plants will be able to be pricked off much easier, and without suffering so much damage at the roots, than they would if the seed were sown in soil too rough in texture. I prefer 48-size pots,—they are so very convenient for shifting about,—and cover them with moss to keep

the soil moist without such a frequent use of the watering-pot as would otherwise be necessary. It will be scarcely requisite for me to say, that as a matter of course the moss must be removed immediately the seed germinates, as the young plants will be so weak as to be quite unable to stand ordinary rough usage; and, moreover, quickly damp off. Covering seed with moss is very well, provided the practice is not abused by leaving the moss on the pots until the young plants commence pushing through it, when of course it does a much greater amount of harm than good. The seed-pots should be put in a temperature of about 75°, such as a cucumber-house or warminery; and as soon as the plants are fit to handle, they should be potted off into small 60's, using the soil, as before advised, without sifting, and the addition of a little thoroughly decomposed manure. Now push them along vigorously; and as soon as they require it, shift into 48's or 32's, and keep them growing.

It is a common practice to dry off the bulbs as soon as they get a nice size, and give them two or three months' rest, which is not required, our object being to get them as strong as we can by the season for flowering. Seed sown in May or June, if kept growing and managed well, will make splendid plants for blooming the following November twelvemonth; and sown early in February, it will produce pretty little roots for flowering the next March twelvemonth. I am unable to see the utility of keeping a lot of old roots about a place unless good varieties, when in the space of twelve or eighteen months plants full of vigour, both in leafage and flower, can be obtained with very little more trouble than the stowing away, shaking out, and repotting of the old roots. Of course I would not by any means advise a wholesale destruction of roots after the plants have done flowering, but would keep those only which are really first-class, and consign the others to the rubbish heap without the slightest feeling of compunction. In a batch of seedlings, even if the seed has been very carefully selected indeed, some will be very poor and not worth growing, and it requires as much labour and room to be bestowed upon them as the very best. The seed should be saved from those plants which have the properties of stout broad petals, short stiff flower-stalks, and dwarf finely marked foliage. If there is any desire to keep a good strain, it is quite impossible to do so if the seed is saved indiscriminately from the whole collection as soon as they have finished flowering. The corms that are to be preserved should be gradually dried off, and the pots laid on their sides in any shady out of the way corner where they will be protected from the wet, and some time in September repotted in fresh soil; and now, as in all stages of their growth, the top of the corms should be just out of the soil. When in full growth, the plants will require a sufficiency of water without saturation, and an occasional supply of weak manure water will be of immense benefit to them.

The preceding has been written more directly in reference to *Persicum*, the best kind for indoor culture, though for the hardy kinds, to grow them out of doors, they require a nicely sheltered border of light rich soil, and to be protected with a covering of coal-ashes or cocoa-fibre during the winter, until the plants show signs of growth, when it must be removed. They are very pretty objects in the spring, if the frost does not injure them; or they can be potted and kept in a cold frame, and flowered in the conservatory, which will be the best plan to ensure the safety of the flowers. With the exception of *Europæum*, which blooms in August, they all flower early in the spring. The following species are hardy, with the exception of *Persicum* and *Macrophyllum*: *C. Atkinsii* is a very beautiful cross between *Coum* and *Persicum*: the lovely white flowers have a deep crimson centre, and are produced very profusely, and the leaves are nicely marbled; *Atkinsii*, unlike others of the genus, requires covering an inch or so with soil. *C. europæum* has small reddish purple sweet-scented flowers, and leaves marked with an irregular band. *C. hederæfolium* is a fine species; large flower, white changing to rose, and nicely scented. *C. ibericum*: flowers rosy purple, with dark centre and prettily marbled foliage. *C. macrophyllum*: this is a fine Algerian species, with beautiful flesh-coloured flowers. *C. persicum*: the flowers of this magnificent species vary from the purest white to deep purple, with innumerable intermediate shades; some of the white flowers have beautiful rosy, and some red centres, whilst others are entirely selfs. *C. vernum* is a very good kind; nicely marked foliage, and bright red flowers.

GEORGE GORDON.

THIS WORLD.—They take very unprofitable pains who endeavour to persuade men that they are obliged wholly to despise this world and all that is in it, even whilst they themselves live here. God hath not taken all that pains in forming, framing, furnishing, and adorning this world, that they who were made by him to live in it should despise it; it will be well enough if they do not love it so immoderately as to prefer it before Him who made it.—*Clarendon*.

JOSEPH BILLINGS is of opinion that "There is no such thing as flattery. If commendation is deserved it is not flattery, but truth; if commendation is not deserved, it is not flattery, but slander."—"The luxury of grief!"—this, I take it, means to have your old unkle die and leave you 9,000 dollars, and you cry.

THE DIFFERENCES AND RESEMBLANCES BETWEEN PLANTS AND ANIMALS.

Substance of a Lecture delivered at the Russell Literary and Scientific Institution, By Dr. MICHAEL FOSTER.

The lecturer showed that while the distinctions between the higher order of animals and plants were apparent to the simplest understanding, and there was no difficulty in referring, say a dog to one class, and a forest oak to the other, the points of resemblance between the two organisations became so numerous as we descended to the lower orders of both, that it was indeed difficult to establish any positive distinction between them.

Plants and animals are alike in the absence of any fixed outline common to each class. From the mammal, with brains, heart, lungs, and complete nervous system, we pass through numerous forms of animal creation in which some or all of these organs are absent, until we come to a microscopic animal lacking even a stomach, the last organ to disappear, and presenting no other form than a minute drop of living jelly. Yet this tiny living being has powers of locomotion, and evidences its animal life by devouring a vegetable nearly as large as itself. Its mode of accomplishing this gastronomic feat is curious: it spreads itself out something like a mass of dough prepared for an apple dumpling, and then enveloping the plant as though it were the apple, absorbs its nutritious properties, subsequently expelling the remainder.

As the lower orders of animals dispense with brain, heart, and lungs, and nervous system, so the lower orders of plants show that flowers, leaves, and roots are not essential to their existence. The microscope shows the difference between the smallest portion of muscular tissue or woody fibre taken from the higher orders of animals or plants, but even the microscope fails to detect differences between the structure in the lower forms of life. Chemical analysis had formerly been relied on, and while albumen and fibrine were believed peculiar to animals, starch and cellulose were thought to be possessed by plants alone. Closer research has shown that these constituents are common to both orders of life.

The definition of Linnæus was: Plants live; animals live, move, and feel. Microscopic research has shown that many plants possess a power of independent motion. In the protoplasm from the hair of the nettle symptoms of this movement can be discovered, while many plants, by means of ciliary action, exercise independent locomotion.

The evidence of feeling in animals devoid of speech is shown by a muscular contraction complex in proportion to the movements of which the animal is capable, but always out of proportion to the force employed. The prick of a pin, for instance, causes a greater movement than the mere amount of pressure would warrant; this is occasioned by muscular contraction, and in the absence of any other sign we accept it as proof of the animal feeling. But a similar contractile movement is observable in many plants, and the one known as "Venus's fly-trap" is an example of a spring set by molecular forces, and let loose when stimulated by touch.

All plants begin life as animals, the earliest visible form of both is alike, consisting in each of a primordial cell subsequently enlarged and subdivided.

One of the principal differences between plants and animals is the nature of the nutrition they require. To the former the simple elements of earth, air, and water form all they require, but the latter must live on something vegetable or animal that has before had life. Again, the great difference is that discovered by Dr. Priestley, that while plants give out oxygen and absorb carbon, animals perform a reverse operation.

The beneficial operation of this law of nature was eloquently described by the lecturer, who dwelt on the true force stored up in the world's fuel, and showed that while it is the function of animals to use, waste, and destroy this force, it is the property of plants to concentrate and hoard it for the world's use.

The points of resemblance between plants and animals are many and intimate; their absolute distinction hard to be defined. One is the web, the other the wool, and their connection is one of deep interest and importance.

FIELD MICE.

At my home, in Otterndorf, the northern part of Hanover, my father's barn and others are overrun with what are called ground mice, and they are so numerous as to have eaten all the last season's crop and the autumn sown wheat and rape. Can you, and if so, will you, obligingly give me any information you may possess as to the best mode of destroying them? I make this request on behalf of the Agricultural Society at Otterndorf, who have already tried to destroy them by poison, but cannot succeed. Some of the members of the society are under the impression that at one time these mice were very numerous in England, and destroyed by some other means. *H. v. Seht*.—[We can only recommend you to encourage all the natural correctives—owls, hawks, &c.]—*Agricultural Gazette*.—[Those who nail up owls and other mice-eating "vermin" birds upon barn doors should think of the plague of mice, which is as surely coming to England as the gamekeeper is eradicating sparrows, hawks, owls, ravens, jays, magpies, &c.]—*Worcester Herald*. I have the pleasure to state that your Foreign Correspondent may in a few months get rid of the mice, if he will just follow my plan. I recommend the old figure-four trap, which is the very best trap for mice, whether indoor or out, but I do not recommend the old style of having a brick, but get slates about 1 foot long, not longer, as large heavy slates or bricks will not go off so easy. Now, first of all, let *H. v. Seht* get these slates and place them at the hedge sides, as these mice sleep in holes generally in the fences, and often from twenty or more in one hole. I always use two slates, one for the fall, and the other under, as if only one slate is used the mice will sometimes creep from under. The bait I recommend is to get about equal parts of cheese, oatmeal, lard or fat, also chopped tow. Mix these up together into a paste, so when finished this bait is so handy that it can be spread on the end of a stick without string; and if held for a time before the fire, so much the better, as it sets fast when becoming cold. This bait can be carried in the pocket when the trapper takes his rounds; but I find that one bait will last sometimes for twenty mice. I am sure if he will set twelve to eighteen traps to an acre he will clear his farm in two months. I have caught 170 mice with six traps in six days, and I warrant if he will visit his traps three times after sunset he will soon thin their numbers. There is nothing like traps for mice, it beats owls, hawks, or cats. Cats are not of much use to clear a country; they do not catch them quick enough. Now is the best time to commence, as they begin to breed in March and April.—*R. H. D., Agricultural Gazette*.

THE LANGUAGE OF FLOWERS; OR, HOW JONES LOST HIS SWEETHEART.

A WARNING TO YOUNG AMATEURS.

There is something highly romantic in the idea of a language, silent but expressive, capable of revealing the most tender sentiments and impassioned thoughts through so beautiful a medium as that of flowers. This language has in all times and places commended itself to the young, particularly to those of ardent affections but of timid, irresolute hearts. So thought our friend young Mr. Jones, and so, no doubt, also thought his young lady neighbours, with many others at the gushing period of life. Mr. Timotheus Jones, called by his more intimate acquaintance Timothy or Tim, was a fair young man of the interesting age of twenty-four. He abode with his widowed mother, a kindly, well-preserved old lady, of comfortable means, who always made it a point of ceremony to appear in a silk dress to receive her son when he came home to dinner from the Office, which he usually did with great regularity about half-past five. They resided in one of those genteel semi-detached villas which adorn the suburbs, in the once rural and still pretty locality of Islington. Timothy was an only son, and his mother's idol, whose chief wish in her declining years was to see him blest with a wife, and to superintend and nurse a numerous progeny of grandchildren. Nor did there appear to be any insuperable obstacle to this desirable result. Jones was a well-looking, smishle young gentlemou enough, of a temperament eminently calculated for domestic bliss, and in circumstances equally propitious for matrimonial engagements, holding, as he did, a comfortably salaried government appointment, which demanded no very overpowering sacrifice of time and labour, besides maternal expectations of a substantial character. He was therefore much sought after by the mammas of their acquaintance; nor did the marriageable daughters of such look upon him with unfavourable eyes. There was only one drawback to his becoming a complete lady's man,—a character in his secret soul he ardently aspired to,—which was his incurable nervousness and hashfulness in feminine society. The spirit truly was willing, but the tongue was weak—a calamity of magnitude to a young man of such a romantic disposition as that of Jones. Often when inspired by the presence of some fair young Islingtonian, as he escorted her round the family garden after tea, he would wind himself up to the delivery of some flowery and poetical compliment, which he had concocted with much pains; but no sooner did he attempt to utter it than his tongue clave to the roof of his mouth, and the speech evaporated in a hesitating commonplace remark. At length a bright idea flashed across his mind—"The Language of Flowers." How was it he had never thought of it before? It was the very thing for a youth of his idiosyncrasy; and he determined immediately to carry it out. He set to work and purchased all the treatises he could discover upon the subject, and committed to memory their contents. He rummaged the neighbouring nurseries, driving their proprietors half frantic by pertinacious inquiries after obsolete and recondite plants and flowers of symbolical meaning, under names unknown to science and the trade. He hought such, regardless of expense, whenever he could obtain them. He, moreover, became a subscriber to the GARDENER'S MAGAZINE, and possessed himself of the "Rose Book," and took to rose-growing, which, by means of the aforesaid excellent instructor, much to the admiration of his mamma's acquaintance, he succeeded in doing very well. His flowers became a talk; and in the study of their silent and eloquent language, it was a labour of love to Timothy to produce the most tender combinations to express his feelings towards his gentle acquaintance, which he delivered to them at divers opportunities, even wearing them at them in his button-hole at the chapel which he and his venerable parent were accustomed to frequent. He moreover ingeniously extended the metaphorical language to esculent roots, vegetables, and fruits; so that an amatory correspondence could be carried on at meals under the very parental eye. In this code the glowing hued carrot typified "passionate adoration;" the pale parsnip "fraternal or sisterly regard." Mashed potatoes indicated "crushed affections," while the same esteemed vegetable in its plain state simply meant "benevolent feelings." By the offer of a pear "affection" was denoted; a peach signified "your charms are unequalled;" celery "coolness;" asparagus "an offer of marriage," and so on through the various productions of the garden.

Among the fair visitors who frequented Jones's maternal dwelling, there was one whom his mamma looked upon with especial and hopeful regard; nor was he himself insensible to the young lady's manifold attractions. Arabella T— was decidedly a charming little personage; very pretty, somewhat shy, highly domesticated, and exactly suited to the youthful Timothy. What an excellent match it would be! mentally soliloquised the old lady, in which opinion her son coincided, though his constitutional infirmity had hitherto prevented a declaration of his passion—that is, in words. Many an ardent communication had been made in tender bouquets, passed to the hands of the fair Arabella over the wall; but poor Jones could never muster up courage to confess his affection in speech. Many were the appealing, lovelorn strains, emulating those of "the widowed nightingale," which he poured forth upon his flute as he paraded the garden, as near his charmer's window as he could get, beneath an Islington moon. The Rubicon of Timothy's stream of love remained unforded; but a crisis was at hand.

In the language of flowers the rose is the especial emblem of love, and is prized accordingly by the practitioners of the mute, sweet tongue. The season of roses drew on, and, as the sap rose in the branches of his trees, so an access of nervous resolution rose with it in Jones's heart. He determined that that season should seal his fate. He resolved to bring the matter about by the presentation of one of his choicest specimens. "If she accepts it," exclaimed he, in tones of rapture, "it will show she 'loves' me; if not, my hopes are lighted, and I will become a Ritualist." Now it has already been said that our young friend was great in roses, and one of the most beautiful and forward among the collection he selected to be the ambassador of his feelings when the auspicious moment should arrive. He watched it, he watered it, he liquid-manured it after the most approved recipes; he shaded it from the sun; never Juno cherished and protected her beloved Carthage with more persevering assiduity than was lavished on this flower. At last the period of its greatest perfection arrived; it was of surpassing bigness—quite a show-flower; fit for an enamoured prince to offer to a queen. Arabella was invited to tea; and in the evening, with palpitating heart, Jones conducted his enslaver to an inspection of the rose. In the midst of her admiration at its beauty, with desperate resolution he cut the flower, and, with hand on heart, presented it to the charm-

ing Arabella, who, almost as blushing as her adorer, accepted it, exclaiming with an enchanting smile, "Oh, Mr. Jones, how very ke-kind of you!" and proceeded to place it in the bosom of her dress. But, alas! for the hopes of the luckless Timothy, during the performance of this operation, a whole colony of earwigs that had sheltered in the bottom of the flower, being disturbed, rushed suddenly forth, and dispersed themselves over her dress in all directions with the celerity of light. This alarming invasion demanded more fortitude than was possessed by poor Arabella, who ran about, frantically screaming for them to be taken off; while Jones stood stupefied with dismay, not knowing what to do. At last she was borne indoors, half fainting and hysterical, to undergo a strict search after the unwelcome intruders through the piercing spectacles of the venerable Mrs. Jones.

After this unfortunate occurrence, Jones made many attempts to obtain a reconciliation with his offended mistress, but in vain. At first, she believed it to have been a cruel joke, but was soon convinced of that mistake. Nevertheless, the fright had made her very ill, and she firmly rejected any renewal of his addresses, replying that, however she might esteem and respect him as a friend, &c., &c., she could never think of uniting her destiny to a gentleman who would always remind her with a shudder of those horrid earwigs.

For a time Timotheus was inconsolable. He wore a sprig of cypress and dead leaves in his button-hole. He let his hair and beard grow long, and cultivated a woe-begone appearance, much to the distress of his affectionate mother, painful to behold in one formerly so debonaire, intended to indicate to his friends and connections that his feelings had undergone an overwhelming shock. His flute, in the garden, wounded the ear of night with melancholy strains. Time, however, the great physician for human afflictions, began to pour his assuaging balsam into the lacerated heart of Jones. His flute by degrees became more cheerful; he once more visited the establishment where hair is brushed by machinery; flowers began again to blossom in the wonted button-hole, and, the last time we saw him, he was presenting a huge bouquet of flowers, among which orange blossoms bore a conspicuous part, with an "empressment" speaking volumes, to a very neat pork-pie hat and a pair of irreproachable Balmorals that did not pertain to the charming Arabella.

Clapton.

W. D. PRIOR.

GARDEN CULTURE OF THE POTATO.

A Lecture by ALFRED GOSSET, Esq., of Abbotsham, delivered before the Bideford Farmers' Club, Feb. 5, 1867.

The few observations I am about to make have reference only to the "Garden Culture of the Potato," for I am well aware that what is feasible on a small scale may be impracticable on a larger one. Potato cultivation is a subject which I have no doubt is well understood by many of the members of this club, and I should not have acceded to the request which was made to me to open the question for your discussion, had it not been that I hope in no small measure to reap benefit from the remarks and observations which I trust will be called forth from the many able and practical men who are members of the Bideford Farmers' Club. I believe that by a more careful attention to the culture of the potato, we may to a great extent lessen, if we do not altogether get rid of, the disease which has more or less injured the potato plant during the last twenty years, and render the crop a much more certain one. Mr. Shirley Hibberd, writing on the subject in the GARDENER'S MAGAZINE of the 20th of January, 1866, says: "I live in hope that I shall see the potato murrain swept out of our fields, and the potato so brought under the command of the cultivator that disease shall be the result of bad management solely, and as certainly kept away by good management as we can keep cattle out of our gardens by means of good fences." I should mention that Mr. Shirley Hibberd is one of the best authorities on horticulture of the present day.

In most gardens one-fourth of the ground is taken up with permanent crops, such as strawberries, seakale, asparagus, &c., leaving three-fourths to be cropped. I would suggest that one-third of this ground be appropriated to potato culture, and the rest so managed that the same piece of ground be cropped with potatoes only every third year. Garden ground ought to be rich enough to bear potatoes without any manure, that part of the garden being chosen that was most heavily dressed with stable dung the year before. If the ground is not in good heart, a small quantity of guano or potato manure should be sown in the drill just before planting. I have had excellent crops from ground so treated. When stable dung is used, it should be placed at the bottom of the trench; in wet ground it acts most beneficially as drainage. Fresh dung of any kind is not a proper manure; it is stimulating, and the plant is rendered more liable to disease. The varieties of potatoes are endless, and one of the great benefits derivable from this is the increased facilities given for cultivation in a variety of soils, since some sorts are suitable to a light and sandy soil, and others are better when grown in stronger land; hence it is that we find particular varieties in favour in some districts, and a variety that may prove but indifferent in this part of the country may bear an excellent character elsewhere. In our damp climate, with its average of forty inches of rainfall, warm dry ground should be selected, if possible. I need hardly say that potatoes will not thrive in the shade, or under trees. The potato plant requires an abundance of solar light and heat. For garden culture only, early or secondary sorts should be planted—the earliest being fit to dig at the end of May or early in June, and the latest ought to be out of the ground by the middle of August. The time for planting depends entirely on the state of the weather and the nature of the soil; if possible, they should be planted in February or early in March, but it is essential that the weather be dry and the ground in good working order; otherwise, the operation must be put off. The drills should be from 4 to 5 inches deep, and 2 feet 6 inches apart for dwarf growers, and 3 feet apart for medium growers, and the sets planted 1 foot or 15 inches apart in the drill. Strong growers require at least 4 feet between the drills.

A point to which I would call attention is the practice of soiling or earthing-up the stems; this I believe to be injurious, besides which it has been proved beyond doubt that it throws back the crop a fortnight. I would suggest that the intervals between the rows be well dug with a spade, and the earth broken as fine as possible; this should be done in dry weather, and as soon as the plants are sufficiently through the ground to be distinguished in the rows. I dig up my potatoes as soon as the leaves begin to look ye low. I believe many a good crop of potatoes is lost by unnecessary delay in taking them up, and it is now that the fortnight's time saved by not earthing-up tells, especially if the weather sets in wet at the end of July.

An important point is the treatment of the seed. I will give you a brief outline of the plan I adopt. At the time of digging the crop, I select well-

ripened tubers of the size of a hen's egg, or rather larger. I put them in shallow boxes, each box containing about a peck; these boxes I stow away in a cool dry place. Till the potatoes begin sprouting, the box may be kept in the dark: but as soon as sprouting begins, which I find is usually about the middle of December, they should be removed to some spot where they can be exposed to the light. It is most injurious to allow them to sprout in the dark, as the sprouts become long, white, and very brittle, and the potatoes are rendered quite unfit for planting. With regard to changing the seed, last year I had a proof of the advantage of doing so. I obtained from Mr. Myatt a peck of his Ashleaf Kidney, and planted in the same plot of ground some of the same variety which I had saved myself. To all appearance the two samples were equally good. I found, however, that the crop from the new seed was superior to that obtained from my own,—probably one-fourth better. Potatoes intended for seed should not be kept in a great bulk, as the fermentation they undergo will often destroy their vegetating power. Picking off the blossoms has been proved to increase the weight of the crop, but most of the early varieties have no blossom. A very interesting experiment was made some years ago by Mr. Knight, the president of the Horticultural Society. Wishing to obtain seed from some early varieties which had never blossomed, he carefully removed the soil round the plants and picked off all the tubers; by thus preventing the plant from increasing its underground stems or tubers, it was stimulated to throw out leaves and flowers, producing seed in abundance.*

I shall not allude to that much disputed subject, the potato disease, further than to say that what I have observed of it leads me to the conclusion that the mischief begins underground. The main points are, I believe, to give the potatoes an abundance of room; to dig between the rows, instead of earthing-up the stems; to use care in selecting and preparing the sets for planting, and to dig up the crops as soon as the leaves begin to look yellow. I have followed the system I have endeavoured to describe to you for the last four years, and have had good crops, and entirely free of disease.

When I think of my former mode of cultivating this ill-used and most long-suffering vegetable, the miserable shrivelled sets which had probably undergone the operation of disbudging once, if not twice, before being planted in ground full of fresh rank stable dung, with only six or eight inches between the sets, in drills one and a-half or two feet apart; then the smothering process of earthing up, and this often done twice—my only wonder is that they produced any crop at all. It is only five years since I first took an interest in the subject of reform (potato reform). I know the little bill I have laid before you is a very imperfect measure, but I believe, if its provisions were carried into effect, our gardens would be delivered from a vast amount of corruption.

A discussion followed the reading of the paper, in which several members took part, and considerable interest was taken in the question of potato disease. It was asked whether it was not coincident with the use of artificial manure, and also whether it did not result from the atmosphere which was generated in their growth, and which might possibly be vitiated from various causes. To this, however, no satisfactory answer could be given. Allusion was also made to the different growths, and the following were recommended by the lecturer: Requiring two and a-half feet between the rows: Myatt's Ashleaf, Walnut-leaf, Royal Ashleaf, Early Frame, and Sutton's Racehorse. Requiring three feet: Daintree's Early, Mona's Pride (kidney), Flour-ball, Lemon Kidney, Dalmahoy, Early Oxford, Wheeler's Milky White, Paterson's Victoria, Paterson's Early, and Lapstone Kidney. Requiring four feet: Webb's Imperial and Paterson's Regent.

Calendar.

WORK FOR WEEK COMMENCING MARCH 23.

Kitchen Garden and Frame Ground.

ASPARAGUS AND SEAKALE.—This is the best time in the whole year to sow, and the best beds are raised from seed, without any transplanting. The ground should have been prepared long since, and be now in a friable mellow condition. Dress asparagus beds with manure, and make all ready for the crop of the season. Seakale that has been forced should now be allowed to grow, to gather strength for next season. Remove all the coverings from the stools, lightly fork between the rows, and dress with strong manure.

BEANS AND PEAS.—Sow for succession as required. The marrow peas are the kinds which answer best for present sowing. If any accidents have happened to early sowings, get in a few rows of *Early Emperor* and *Advancer* at once; they will come in usefully between the first earlies and the later marrows. Dress the roots of beans and peas with wood-ashes or soot before moulding up.

SWEET HERBS to be sown and planted. The majority of these do best on raised banks of sandy earth in the full sun.

MARROWS AND GOURDS.—Between this time and the 10th of April, intending growers should determine their plans, and sow the seeds of the varieties intended to be grown for show. The first object will be to secure vigorous plants for planting out in May under hand-lights or in frames, and for this purpose the growth should be slow and steady; no check by cold draughts or injudicious watering, and no hurrying by excessive heat. The customary way of raising marrows and cucumbers is objectionable, because it tends to debilitate the plants, so that when put out they are a considerable time recovering. The first error is in sowing several seeds in the same pot, the separation of the plants causing damage to the roots; the second error is in allowing the seedlings to remain together too long, so that they get drawn, weak, spindling, and unmanageable. We would advise intending competitors to sow the seeds in 60-sized pots, two seeds in each pot. The strongest plant of the two should be allowed to fill the pot with roots, the weakest should be removed as soon as any difference as to strength is perceptible; the plants removed may be potted into 60's to have a chance, but those that remain untouched until they fill their pots with roots will prove the best in the end. Before shifting these, separate the ornamental from the edible kinds; allow the edible kinds, which are required to furnish the largest fruits, to grow as they please; but the ornamental kinds should be stopped, and allowed to break before being shifted. As in growing large fruits it is essential to have the plants in the fullest possible vigour, with plenty of large healthy leaves, care must be taken at every stage in their growth that they never get pot-bound, and never suffer through lack of air or moisture. For the seedlings, a light rich fuchsia compost will be

most suitable, as it will promote the formation of an abundance of roots. After that, good, sound, turfy loam should predominate.

CELERY.—For all general purposes, where there is no intention to snatch an early supply by a half-forcing process, the middle of March is soon enough to sow the seed. It should be sown in pans or boxes, in light rich earth, the seed to be scattered thinly on the surface, and be very lightly covered with very fine soil. If the soil is of a proper degree of moisture in the first instance, no water will be needed till the plants are up; the retention of moisture and the germination of the seed may be promoted by laying a sheet of paper over the seed-pan, or a board or tile may be laid on it, care being taken to remove it the instant the seed begins to sprout. A gentle heat is needful to bring up the plants nicely; but a strong heat is not required, and in fact is injurious. But if there are no means of starting it with heat, it will come on very well kept in a frame or greenhouse, in the full sun, but screened to prevent evaporation. It is one of the advantages of sowing the seed later than is generally done, that there is less need of artificial heat to start it into growth. When the plants have two rough leaves each, it is advisable to draw out a few with the aid of a bit of stick, and pot them singly in thumb-pots, in a mixture of equal parts friable loam, dung rotted to powder, and with an addition of sharp sand. These may be placed in a frame, and must, of course, be shaded, and rather tenderly cared for during the first few weeks. A hundred or more plants may be potted in an hour, and, if carefully treated, these will give an early supply of fine heads. The object of the cultivator should be, by good cultivation, to make these selected plants overtake other people's that were sown early, and afterwards kept starving in the seed-pans. The remainder must be pricked out as soon as they are as large in the head as the head of a young radish—say having four or five leaves each. The way to prick them out is to prepare first a frame, next tread the ground hard where it is to stand. On the hard surface lay turfs, grass side downwards, and on the turfs spread three inches of quite rotten dung and fine loam, equal parts, well mixed together. On this bed plant them in rows carefully; water, put on the light, keep shaded and rather close till they begin to grow; then take the light off during the day as much as possible, taking care to put it on in case of cold rains, or snow, or frost, all of which are possible even up to the middle of May. The plants that were potted will have to be dealt with according to the weather, and other circumstances. They will soon fill their pots with roots, and when they do so—better, indeed, before they do so—shift them into 60-size, with one rather flat crock only in the pot, the soil half dung and half loam, and keep them in a frame, giving plenty of air and water, and exposing them fully to sunshine. By the time they fill these pots with roots, the season will be sufficiently advanced to allow of planting out; and this, like all other processes, must be done with care. As for the general crop, where there is a large demand, potting is out of the question; but it is a great gain to prick out the young plants on a bed of rotten manure in a frame.

Flower Garden.

ROCKERY.—This is a good time to buy in alpine and succulent plants for raised banks and rockeries, as their character can be seen in the foliage, and many will now be in flower. The majority prefer a sandy loam; but places should be prepared for such as love chalk or peat, so that several distinct features may be presented in various parts of the construction. For small gardens, the Saxifrages, variegated and other kinds of Thyme, *Andrietta*, smaller *Potentillas*, and *Sedum*, are the most useful. Choice kinds of alpine should be grown in duplicate, in pots, in case of losses, by which means they can be replaced.

ROSES.—During the next six weeks, and longer if damp weather, is the best time to plant dwarf roses from pots. Plants from last year's cuttings may now be had in 54-size pots full of roots, and the *Chinas* and *Hybrid Perpetuals* will be sure to bloom freely in autumn if planted in a well manured loamy soil. If the plants come to hand in a very fresh growing state, keep them in airy pits or frames for at least three weeks, to harden before planting.

ORNAMENTAL GRASSES.—The following dozen are among the very best: *Agrostis nebulosa*, exquisitely slender and elegant when looked at raised above the eye, above which it is sometimes necessary to raise it from the stems being nearly as fine as a hair. From this cause also a healthy patch of the plant in flower looks like a little cloud lying upon the ground. You can see the dense inflorescence, but not the stems which support it, and the whole has a fairy-like aspect. *Agrostis pulchella* is not so elegant, but quite as desirable from its prettiness and distinct bushy habit. *Stipa pennata*, a well-known and elegant feather grass. *Papilatherum*, or *Milium multiflorum*, the most gracefully drooping, slender flowering grass. *Briza gracilis* and *maxima*, well-known, popular, and good, but not so good as others mentioned here less seen in cultivation, but quite as cheap as the *Brizas*. *Lagurus ovalis*, the soft and pretty hare's-tail grass, quite indispensable from its distinctness. *Setaria macrochata* and *germanica*, handsome, free-growing, and noble grasses, very useful and striking for vase decoration. *Eragrostis elegans*, second to no grass in existence for beauty when the inflorescence is springing from the ligule, or indeed at any time; it, like other grasses, may be cut with advantage in two or three stages; the first cutting will be quite distinct from the last. *Hordeum jubatum*, the most elegant of the barleys, but which must be cut in a very young state, or it will fall to pieces in drying. *Sorghum bicolor*, with a pendulous and elegant inflorescence; the *Pampas grass* cut when in its prime, and *Bromus briziformis*, somewhat like, but larger and far prettier than a briza, but with a peculiarly elegant habit, drooping and arching in a singularly graceful manner. The seed of these may be had from most respectable seedsmen, and should be sown in the open border about the end of April, or better still in pots in a cold frame in March, and then divided and planted out about the end of April. In this way they would escape being mingled with the common grasses, the seeds of which are always plentiful in the ground. They might be planted here and there in vacancies in the mixed border, and would delightfully vary it. But to grow them specially for cutting, not an unwise plan, the best way would be to give them a little bed to themselves in the kitchen-garden or nursery, or any such place. They would then be more under the eye, and more likely to get cut at the proper time, *i. e.*, when fresh, and young, and perfect.

TRITOMA UVARIA FROM SEED.—The best way of raising them from seed is to sow on a warm bed about the beginning of March, or as late as the month of April, if found most convenient. They should not be sown on a hotbed, as too much heat is not good for them, but a nice warm bed, say one that is nearly spent, will exactly suit all their requirements. At the end of June, take out the seedlings with a ball, and plant them in the open ground; during winter cover with straw. In the following spring divide and plant

* This experiment shows clearly the connection between the tuber and the blossom, and that, conversely, the growth of the tuber may be promoted by preventing the development of the blossom.

them separately, where they may be left to take care of themselves for the remainder of their natural lives, the only protection requisite during the winter months being a conical heap of straw. The easiest way, however, of multiplying them is from the strong side-suckers from old plants in the spring; the end of February to the end of March is the best time for amateurs to divide them, and the divisions should then be planted immediately in a rich sandy soil, where they are sure to do well without much attention.

RANUNCULUS BED.—As soon as the plants begin to push through, the bed should be carefully trod over between the rows, firmness of the soil being a prime element of success in the general cultivation. If the weather is dry, they may be watered night and morning, and if the soil has not been so liberally manured as it ought, weak manure water may be used. The ranunculus likes a moist and generous soil, but nevertheless it is a mistaken notion to water it either frequently or copiously. Artificial watering never does as much good as is expected of it, and if it can be dispensed with it will be better for the plants. It is a good plan to mulch the bed with moss or old tan, or even ancient and well-sweetened manure, placing the dressing neatly along the rows. Such a procedure will frequently obviate the necessity for watering, and carry the plants through till the rain falls.

FORMING GRASS LAWNS.—When properly managed, and allowing plenty of time, the best turf is obtained from seed; but the seed should be obtained from a first-rate house, known for its care in selecting and sowing grass seeds, or a worse result may happen than by the use of turf from a fat meadow. The grass seeds sent out by the leading houses in the trade are all that can be desired; they are selected so as to be adaptable to every variety of soil and position, so that the purchaser only need to specify whether he wishes for a lawn under trees, on a bleak hill, or on a damp loam, and a mixture of seeds will be sent for the purpose. In fact, seed is invariably used now in laying down lawns in grand gardens; and at the Crystal Palace, Kew, Kensington, and Aldershot, those who rejoice in good turf may have examples of what may be done in this way, for all these swards were sown down with mixtures of seeds. The laying-down of turf, however, is not only a great saving of time over producing turf from seed, for the fact is, the moment the work of laying the turf is completed, the lawn is made; but with seed we must wait a year before we can say that we have a really good turf. A deep sandy loam produces the finest turf, but the more sandy, the more apt it is to get burnt in summer-time. Fat lawns carry good swards if care is taken to keep down daisies, docks, and dandelions; these should all be spudded out, and if the extremities of the roots cannot be removed, they should be covered with an inch of salt before the holes are filled in; this will kill the fragments of roots that remain in the ground, and the turf will soon join over the places whence the weeds were removed. On clays and rich loams the grasses always show a tendency to become coarse, and whatever dressing is applied should be of poor sandy stuff, with an admixture of old mortar, road-sand, or other gritty material free of stones or brickbats. Manure should never be applied to grass on sound loams and clays; as such water as you please when it is needed, but manure will cause a rankness of growth that is very objectionable. On the other hand, poor sandy and peaty soils will produce a closer and richer turf, if annually manured. Rotten dung spread over the surface and broken up, and scattered an inch deep during March, will bring the grass forward, and if well rolled when quite dry, its appearance will not be unsightly, and in a very short time the grass will rise through it and justify the act. But superphosphate of lime, at the rate of three hundredweight per acre, is the best dressing for grass on poor soils, as it encourages the growth of clover, without which there cannot be a good turf. Before grass seed is sown the ground should be drained, if needful, then dug deep, and the bottom spit mixed with the top, if the staple is good, then raked quite level, all stones and hard rubbish, dead roots, &c., removed, and the whole rolled smooth and firm. On a fine day, when the ground is pretty dry, and no wind stirring, proceed to sow. The proportion of seed required is one gallon to every six rods. Have ready a sufficient quantity of fine dry earth to sprinkle the whole surface half an inch deep. Scatter the seed rather thickly, and throw over it the fine earth, and roll several times to render the whole firm and smooth; and if sparrows abound in the neighbourhood, stretch some white threads across the ground about three yards asunder, and they will be scared long enough for the seed to germinate. Old lawns that have bare patches may be renovated without disturbing those parts that are in good trim. Strip off the grass, or dig it in over the spots that are poor, rake smooth, and sow as just described. But generally turf that is poor in grass is rich in weeds, and to dig them in is to make sure of their coming up again; therefore the removal of the turf is the safest course, as when rotted it is valuable for potting, and the loss can be made good with soil brought to the spot. Grass that is merely thin, and not weedy, may, if the soil is not sour and exhausted, be greatly improved by sowing over it now a good lawn mixture, and then covering with fine soil and rolling in. Turf that is smooth and bearing an even plant, but rather thin from having been many years mown without aid of manure, may be restored to a fine condition by means of occasional thin sprinklings of nitrate of soda in the months of April, May, and June.

Greenhouse and Conservatory.

BALSAMS AND COCKSCOMBS must be shifted on and kept warm. Any check by getting pot-bound, or for want of water, will spoil the bloom. In repotting have the soil and pots warm; let the shift be made quickly, and without leaving the plants about to be chilled, and water with tepid water. We believe many of the failures in growing these annuals arise through neglect of these small matters.

CALCEOLARIAS of the shrubby kind to be shifted on as soon as they fill their pots with roots. A liberal use of chopped moss in the compost is a great help to the roots, and if peat is plentiful in the district, use one-third part in the mixture. Herbaceous Calceolarias must have no check, no artificial heat now, and must be kept clear of fly by smoking when required. In shifting these, put them lower in the next size pot than they were previously, to shorten the stem and promote new roots from the collar. These must be kept airy, or they will run up too high, and bloom weak.

CAMELLIAS, AZALEAS, AND RHODODENDRONS going out of bloom in the conservatory to have all the remaining flowers clipped off, all seeds removed, and after being well syringed to be shut up close and warm, to promote a vigorous growth. Camellias inclined to be leggy, remove the top buds, or shorten back.

CONSERVATORY to be kept moderately close while east winds prevail, or the plants in flower will suffer. No need for fire-heat now unless there

are many newly-introduced stove plants. Water the borders liberally; stop climbers.

FUCHSIAS for exhibition must now have large shifts. Pot off cuttings as soon as rooted; never suffer them to starve in the cutting pans, and place them in moist heat to have a good start.

LILIUMS.—If these are growing freely in good turfy peat, a top-dressing of half rotten cow-dung will now be beneficial. Give plenty of water, and take care the pots are not exposed to hot sun.

Forcing Pit.

CAPSICUMS AND TOMATOES to be potted off and put in a moderate heat to encourage new roots. Use light rich soil. Tomatoes wanted early may be thrown into a blooming state by allowing them to get pot-bound in small sashes; as soon as they show for bloom, shift to forty-eights; and when they fill those pots with roots, shift into six or eight-inch pots. By this method a very early crop of fine fruit may be secured in pots, and there is generally plenty of room to ripen them under glass after the end of May. In shifting, none of the crocks should be taken from the roots, but the ball should be lifted without damaging a fibre into the pots they are shifted to, and the compost filled firmly round it. As the fruits swell, use strong manure-water, and give plenty of it.

CUCUMBERS.—Newly-established beds should be carefully aired every morning, to let off rank steam and prevent damping. Stop regularly before the fruit; never allow any runner to go away neglected, or the distribution of the sap will be unequal, and the fruiting unsatisfactory. Plants that are worn-out should be destroyed; it is a folly at this time of the year to attempt to renew their vigour by cutting back. If there is a great demand for cucumbers, and the supply runs short, it is worth remembering that half a fruit may be cut and the other half left to grow. In fact, a large cucumber may be taken at three cuttings, and furnish three dishes in succession instead of one.

FRENCH BEANS must be kept near the glass, have as much air as possible, and while bearing have regular supplies of manure water. We find that passing a dry brush over the flowers when the sun shines promotes the setting of the pods.

PINES, VINES, PEACHES, and other subjects in the forcing-house, see notices of the last few weeks. Vines will require special attention now, as they are in full vigour: those colouring their bunches to have plenty of air and a brisk heat. Those newly started to be frequently syringed, and the borders kept warm and moist. Newly-set bunches to be thinned with great care; the less handling the better. Remove useless growths, and stop laterals.

MELONS that have suffered a check will now be showing fruit, which must be removed, unless the plants are evidently sufficiently vigorous to bring it to maturity. If a few fruits of any small variety are wanted early, the plants may be thrown into a fruiting state by letting them get a little pot-bound in six-inch pots on a warm tank or flue. Melons newly planted to have a generous heat, and as much moisture as cucumbers; but those established and in vigorous growth to be kept drier than young plants, and to have all the sunshine. Night temperature, 65°; day, 70° to 75°. Sow now for a good crop to fruit late in the summer.

Fruit Garden and Orchard House.

ORCHARD HOUSE.—Trees in bloom to have air in abundance. Some slight agitation amongst the blossoms will help to set them. Keep the air as dry as possible till the fruit is set, and while stoning be very careful not to let them get either too wet or too dry at the root. Trees swelling their fruit in the early house to be assisted with manure-water.

WALL-TREES must have protection of some kind in all except the most favoured districts. If any pruning or nailing has been neglected, see to it at once.

Stove and Orchid House.

ORCHID HOUSE will require an abundance of atmospheric moisture now and general attention to plants newly potted and those coming into seasonal growth. Give water cautiously to such as are yet dormant; but encourage growth by sprinkling water about the floors, and keep an average day-heat of 80°. Increase the temperature and the amount of atmospheric moisture to encourage growth. Be careful to water so that there is no lodgment of moisture about the crowns of plants that have not yet started. Every plant in the house should be looked at now; those on blocks require fresh dressing with moss; those in pots with peat. On bright mornings raise a good steam by sprinkling the pipes. Plants to be increased should have a sharp knife passed through the stool, so as to separate one or two dormant pseudo-bulbs farthest removed from the parts that are throwing up leaves or flowers. When these partially separated bulbs begin to grow, remove them completely; pot in small pots with chopped moss, peat, and sand, and place on a moist heat to encourage roots. Vermin will be active now, and must be destroyed, or there will be great injury done to the rising blooms. Shading must be ready in case of sudden outbursts of hot sunshine, but it is not to be used more than can be avoided at present.

STOVE CLIMBERS must be encouraged to grow fast, and training must be delayed as long as it is safe to do so, as training checks the growth. A large shift, and the use of rich soil, then to put on a good bottom-heat of 70° to 80°, and have plenty of moisture, are the conditions under which specimen stove plants will best progress. Shade after shifting. There must now be abundance of atmospheric moisture in the stove, and this with proper shifting, good rich soil, and a regular temperature, will do more to keep down fly and red spider than all the nostrums in the world. Begonias, Caladiums, and other quick-growing soft-wooded plants, will do best on tan, which should be frequently sprinkled with diluted drainings from a dung-heap, to enrich the atmosphere with ammoniacal vapours. Economise sun-heat to save fuel.

Correspondence.

DAMPING OFF, TO ARREST.—As you have received my observation upon stocks so well, perhaps you will permit me to make another communication which has proved to me most valuable, and may to other amateurs. I am in the habit of raising a large number of seedling geraniums, zonals and pelargoniums so-called. I adopt your method of sowing on the 20th of February, and find a great many (zonals) flower the first year. I am plagued, as other amateurs doubtless are, with the young plants, not only of geraniums, but stocks and other things, damping-off. The plan I adopt is,

when the first one has damped-off, although the plants have only their seed-leaves, to transplant them into pans an inch apart every way. The little plants are raised with the point of a knife, retaining as much earth as possible; and by taking the plants carefully up with a knife sufficient earth can be retained not to check the plant. And in planting them into the seed-pans, first making the holes into which they are to go, I plunge the tiny plants nearly up to the seed-leaves. By this method I find I get rid of my plague, and lose few, if any; whereas, if I leave them in the seed-pans, the damping goes on, and then good-bye to my stock. I have noted and tried the various methods pointed out in your journal to remedy this evil, but owing perhaps to my clumsiness, or other causes, I have found the evil has not abated. I then hit upon the method above suggested, which I have found to answer most admirably. I am aware professed gardeners have other means of ridding themselves of the nuisance, but it must be recollected that nine-tenths of amateurs have not the gardener's appliances. One house must serve for all their purposes—and often only a sunny southern window. My hint, if you think well of it, is only intended for amateurs; for I should not pretend to instruct a gardener. With these remarks, as with the others I made, I say, do as you please.

SORGHUM TARTARICUM.—A paragraph in your paper of the 9th instant assumes that the above-named grass is identical with *Sorghum* (*Holcus*) *saccharatum*, respecting which a good deal was said and written a few years ago; but which, notwithstanding its doubtless excellent qualities, fell gradually into disrepute through its tardiness in ripening its grain in our climate. A similar statement has also been made more than once, in a leading gardening journal, consequent upon the popularizing of the *S. tartaricum* by J. Hullett, Esq., of Cosham. As the same opinion seems to be also prevalent amongst the trade as well as private individuals, for the better information of your numerous readers we venture to correct this error, and beg to inform you, that though nearly allied plants they are quite distinct from one another. In order to give you an immediate and self-evident proof of their distinctness, we enclose you a few grains of the seed of each, in which particular you will perceive that they differ as black differs from white, *S. saccharatum* being black and *S. tartaricum* (?) white seeds. Whether or not the *Sorghum tartaricum* (?) will ever become, in the usually accepted sense of the term, a "cereal" in this country remains to be proved. That it has excellent properties, and that its seeds would make a very fair kind of bread, we are not disposed to doubt; and the abundance with which they are produced, in common with the habit of the whole family, will be a great recommendation, provided it is found to ripen its seeds in all summers in this climate. This is the chief question concerning it. There is, however, another *Sorghum* which we believe will be found to ripen its seeds more readily in northern climates than any, and we should strongly recommend those who are disposed to attempt their cultivation to try it. As regards its habit and culture, it does not differ from *S. tartaricum* (?), and should be sown out of doors in April—or March, if the weather change to more genial temperature. This species is known as *Andropogon sorghum*. Its seeds externally are of a red-brown colour, white within, and are produced in wonderful profusion. We have thought so well of this plant as to consider it worth while to bring it into prominence, as possessing qualities more favourable to our climate than *S. tartaricum* (?). We have therefore been induced to offer seed of it by public advertisement. It may be well to mention that we have seen this species (*Andropogon sorghum*) catalogued as synonymous with *A. rubens*, though it is certainly not identical with that kind. In conclusion, having in some measure shared the anxiety which our esteemed correspondent Mr. Hullett has had, respecting the supplying of his 20,000 applicants for seed of *S. tartaricum* (?), we think it will not be out of place that the public should be informed that it has not been without some considerable expense to himself that Mr. Hullett has been able to satisfy their claims.

Covent Garden, London.

HOOPER & Co.

Replies to Queries.

Orchids for Cool Houses.—S. B., Walton.—The following are good and well adapted for cool treatment; they are, moreover, comparatively cheap: *Cypripedium insigne*, *Disa grandiflora*, *Epidendrum vitellinum*, *Odontoglossum grande*, *Limatodes rosea*, *Bletia campanulata*, *Miltonia spectabilis*, *Lycaste Skinneri*, *Lycaste Deppei*, *Oncidium flexuosum*, *Renanthera coccinea*, *Phajus grandifolius*. We find, on reference to a trade catalogue, that one small plant each of these twelve (save and except *Disa grandiflora*, which is not entered at a price) may be obtained for £10. Probably the finest cool orchid known is *Oncidium phalænopsis*, but it is far too costly to be entered in this list, as a good bit of it would fetch £20 or £30, and a moderately good specimen £100. If the directions on cultivation given in the "Garden Oracle" for 1865 are followed by S. B., there will be experienced but little difficulty in the management of the above.

Pillar Plants for Greenhouse.—S. B.—One of the best plants for a pillar is the variegated *Cobea scandens*, but it must be allowed to ramble over the roof; in fact, it needs plenty of room. *Fuchsia corallina* makes a grand pillar plant. *Lapageria rosea* is superb. *Jasminum grandiflorum*, *Tropaeolum Lobbianum Eclipse*, and *Cooper's Defiance* are also useful in their way, but there are hundreds of equally good things, and we suppose the names of a few to be preferable to the names of many.

Acacias.—S. B.—There is no difficulty in growing any number of greenhouse acacias, but the best way to deal with them is to plant them out in conservatory borders, in a mixture of good turfy peat, leaf-mould, and loam, and let them grow almost as they like. You then have the natural grace that belongs to them. Cuttings of young shoots, taken off with a heel, strike readily under hand-lights in sandy peat during the summer, and should be grown on in pots till large enough to turn out. They may also be propagated from pieces of the large roots. The greenhouse kinds require a temperature averaging 40° all winter—it should never be lower than 35°—and at the turn of the season, when they begin to push for bloom, more heat and moisture. The most useful kinds are to be had at all respectable nurseries. The following are the best for amateurs: *affinis*, *amœna*, *armata*, *dealbata*, *decurrens*, *dolabriformis*, *Drummondii*, *emarginata*, *floribunda*, *grandis*, *juniperina*, *rotundifolia*, *lophantha*, and *taxifolia*.

Water-Lilies.—Robert.—You must give up the idea of having the red and blue flowered water-lilies in your open-air aquarium. The beautiful *Nymphaea corulea*; *Devoniensis gigantea*, *rubra*, *stellata*, *versicolor*, and

others, insist on having the water hot; and if you make a scrutiny of the basins at the Crystal Palace, where these lilies have charmed you, you will see the pipes by which the water is heated, and it will be easy to discover by the species and their degrees of luxuriance where the water is warmest and where coolest. There are five hardy *Nymphaeas* in general cultivation, and about fifty more that invite the attention of wealthy horticulturists.

Salvia gesneriflora.—R. J. T.—This should be showing its bloom spikes now, and should therefore not be shifted, but give it plenty of liquid manure, or put a spoonful of genuine Peruvian guano on the surface of the mould every three days, and wash it in with water. If not now showing bloom it may be shifted, and you will have to wait for bloom till next season. Shorten the shoots of *Justicia carnea* to five or six inches in length, shake it out and repot in rich compost, plunge in bottom-heat, shift again as the plant advances, syringe frequently, and by the middle of July it should be a handsome specimen, with from fifteen to twenty fine heads of bloom. The tops now cut off, if placed in bottom-heat—say, a cucumber frame at work—would soon make fine young plants. *Gaillardias*, *heliotropes*, *lobelias*, and *gazanias* will all bloom this season if sown immediately, and pushed on in heat; but you ought to have set them to work on the 1st of February. The scarlet *Linum* we have always advised to sow where it is to bloom, and to give it no artificial heat at all. *Campanula pyramidalis* is a biennial. *Tacsonia ignea* will not flower the first season.

Cydonia Japonica.—J. Thomas.—The *Pyrus Japonica*, more correctly known as *Cydonia Japonica*, is increased by layers. It may also be worked on thorn-stocks. The layers are put down in September in the usual way, and are allowed to remain till the September following, when they are taken off and planted in nursery rows until strong enough to be removed to the places they are to decorate. It will grow in any good loamy soil or clay, and makes a very beautiful bush or standard. But the best place for it is a dwarf wall.

Veetis.—We saw the plant you inquire about in Messrs. Low and Co.'s nursery, Upper Clapton, last summer. We cannot afford any further clue to it.

Stocks.—Reader need not be startled to find that one account does not quite agree with another. Our business is to progress, not to hold fast to any system when we have discovered a better. The "incendiary advice" will be followed by some thousands of cultivators this season, and we shall hear from some of them that it embodies a golden rule. It is not our mission to bolster up anybody's book, and severe impartiality and the love of truth and science may compel us frequently to run counter to the most reputable of authorities, no matter who they are. We are not at all surprised to hear that in your district (Newry) broccoli, cabbage, wallflowers, rockets, antirrhinums, &c., after standing the winter and surviving the great frost, are now perishing fast. The mild weather that followed the frost started them into growth, and put them in condition to be quite ruined by the return of cold weather. We saw a fine gathering of rhubarb made on the 20th of February from open quarters in a very exposed district, but not a stick can be got now, even with the help of straw, &c. Those who pruned their roses early will catch it awfully.

Plant Case.—Miss Maling's indoor plant case, as made by Mr. Gray, of Danvers-street, Chelsea, is an admirable contrivance in which to grow ferns and a few of the smaller orchids, with the aid of hot-water, and also to display forced flowers and fine foliage plants for a time; but we do not think you can do much with it for forcing roses, because of the necessary scarcity of light. Nor should we expect to do much in the way of propagating in it, though cuttings of plants may be struck almost anywhere in damp and shade. We know of nothing better in the way of plant cases, and for ferns especially it is admirable. On this point we speak from knowledge, having had cases of this make in use ever since they were first introduced to public notice.

Small Greenhouse.—Broom.—Your little house, 10 feet by 8 feet, need not have so high a wall as you propose; 2½ feet will be plenty. Otherwise your plan is good. It would be well to have a small ventilator at each end, and none in the roof; when extra air is wanted, the door can be set open. You could not do better for keeping frost out than have Hays's constant stove, which is cheap, elegant, and effective, and when out of use can be taken away for the season.

C. B. Wollaston.—We really have not time to make the search you desire.

Oranges and Pomegranates.—Reader.—These fail in private gardens more through being starved than through want of heat. The soil in the pots and boxes is allowed to get sour and effete, whereas it should be renewed every year by the removal of some of the old stuff round the sides, as deep as can be without injury to the roots. The new soil should be lumps of turfy loam and cakes of old cow-manure rammed in hard, and during the few hot months liquid manure should be given once a week. By thus insuring free summer growth, bloom and fruit will result in their season. They may be wintered at an average temperature of 40°, nay, we have kept them in cool houses without fire-heat, except to just keep frost out, giving them a steady rise of temperature in the spring to start them nicely.

Covering a Porch.—B. B. B.—The quickest, safest, and cheapest covering would be *Virginia creeper*. A little less quick would be *sempervirens* roses, very beautiful, fast growing and abundant bloomers, one only to each pillar. These would require plenty of water, and the ground heavily manured before planting, as the chalky substratum will try them. Less quick than the last, but in such a hot place very suitable, *Ceanothus papillosus*, which would require some good turf chopped over with rotten cow-dung. *Hedera regneriana*, a grand ivy with huge leaves, would run up quick, and be rich and shady. *Clematis cerulea* would rejoice in that hot, dry, chalky bottom, and go to the top of the pillars at a rapid pace. Be content with only one kind of plant, have no mixtures. You are in time now to plant any of them from pots.

Celostia pyramidalis.—W. Wilson.—It is best to make three sowings, one in February, another in March, and the third in April, and these give a good succession of bloom to Christmas, or even into the new year. To start the seeds strongly and well a bottom-heat of 80° to 90° is necessary; sow the seed thinly, but directly the plants are up place them close to the glass, and give air freely to keep them dwarf. As soon as the plants are sufficiently strong, pot them off into "thumbs," and give them a bottom-heat of 80° at the least, a moist atmosphere, and as much air night and day as the heat of the frame, pit, or house, will admit of, always bearing in mind that the night temperature should not fall much below 60°, while in the daytime a brisk moist heat rising to 80° or 90°, with sun-heat and moisture, will not be too much. As the pots fill with roots, shift into those of a larger size. Fine plants may be grown in 11-inch pots, but if you wish to attain the fullest perfection, 13 or 15-inch pots will be necessary.

The Gardener's Magazine.

SATURDAY, MARCH 30, 1867.

CABBAGES ARE IGNOBLE SUBJECTS FOR HORTICULTURAL SCRIBES, but they dare not be ignored because of their ignobility. The fact is, the time has come for the sowing of cabbage-seed, and very much of the profit of the business must depend on the proper doing of it; and when profit is in consideration, we agree to forget the meanness of the subject in view simply of its utility. So in the matter of cabbage, the meanest of vegetables claims a certain degree of respect, and in every good garden now the prudent cultivator is preparing his seed-plots, and hopes for a fine day soon that he may sow the seed. At this juncture, then, we propound the question—Do you, good reader, know a good cabbage from a bad one? The boldness of the query will, we trust, be pardoned because of its importance, and the more so that we wish to make an observation on cabbages in general. A considerable number of the best esteemed varieties form large, compact, white hearts, that are as solid as stale bread. The judges at shows take hold of a cabbage and press the heart with their thumbs, and (perhaps) award the best prize to the hardest hearts they can discover. Now we venture the doctrine that hard-heartedness in a cabbage is fully as objectionable as in a man or woman, and that people who go for compactness, solidity, and whiteness in the hearts of cabbages, go for qualities that are altogether objectionable. As a rule, there is comparatively little flavour in a white-hearted cabbage; if there is the smallest tinge of pink added, the flavour is decidedly rank and objectionable. Then, in common with all blanched vegetables, the white cabbage is comparatively innutritious. This would not matter if—as in the case of seakale, lettuces, endive, and some other things that are blanched—delicacy were obtained by the sacrifice of colour; but that it is not so in the case of cabbage may any day be determined by placing on the table two dishes equally well cooked, one to consist of the compactest white heart that can be found of Sugar Loaf, Enfield, or Battersea, and the other of little Collards or Brussels sprouts, or small loose plants of any of the larger kinds that have not hearted well. If we look at the matter as one of economy only, the green vegetable will supersede the white, for it is better flavoured and more nutritious; moreover, it takes less from the soil and more from the atmosphere than the other for the construction of its fabric. To be sure, blanched vegetables of all kinds consist in great part of water, yet whatever of fibre and secretions they contain must be gathered up from the roots, for not having seen the daylight they can have obtained but a small proportion of their substance from the atmosphere.

But, to avoid making a scientific question of the subject, we are content to recommend the cultivation of small, quick-growing, loose-hearted cabbages, where the object of the cultivator is to place an elegant and salubrious dish of vegetables on the table. There is perhaps not a more useful variety of cabbage in cultivation than the true Rosette Colewort, though, like many other good things, it requires a considerable space of ground, as compared with larger-growing sorts, to furnish a given quantity for table use. It is no wonder that trade growers are perpetually on the look-out for improved varieties of cabbage; for in the garden of the peer, no less than in the plot of the ploughman, some kinds must be grown, and on every day throughout the year cabbages should be visible in some form or other. Having in view to promote the cultivation of the best varieties of this useful vegetable, we say, give the preference to kinds that do not form huge, compact, flint-like hearts, and let all cabbages be cut in a younger state than they are usually taken; for while they are green throughout they are all that we require, but every degree of whiteness is objectionable. Such quick-growing kinds as *Veitch's Improved Atkins's Matchless*, *Early Barnes*, *Early Dwarf York*, *Little Pixie*, and *Shilling's Queen*, with the true *Rosette* or *London Colewort* added, are far to be preferred to the Battersea, Enfield Market, and Large York, which have been generally accepted as the perfection of cabbages. But all these large kinds are good if taken when the hearting process begins, instead of waiting till it ends, and the hearts look ready to burst. Even the *Drumhead*, or cattle cabbage, makes as sweet and tender a dish to accompany a hot joint as any cabbage in cultivation, if used when small, and so on all through. But, as a rule, it is better to grow the small varieties in gardens, and as they may be planted pretty close together, the total produce will in the end be not se-

riously deficient, as compared with the large-growing kinds; but if it is a question of weight for weight we give up the argument, for the large cabbages will carry the day—indeed, the total dead weight of their produce is something astonishing.

The great desideratum of kitchen garden practice is to ensure green vegetables in the months of February, March, and April. How is it to be done? Probably, in ninety-nine of every hundred gardens throughout the country, there is not now a scrap of anything green fit for use. It must be among the Brassicas we should find the materials to tide over until the first supplies of round spinach are obtainable; seakale, asparagus, and roots are the staple products during the three months named, but in some places late Broccolis, and everywhere Sprouting Broccoli, assist in some degree, and then to fill in there must be some kind of cabbage. The terrible frost of January last put to a severe test the various forms of cabbage commonly grown to keep over winter. The destruction of Brassicas has been universal, but some kinds have escaped. First, we must observe that small plants from sowings made rather late last autumn are but little the worse for the weather, and this irrespective of sorts. In a small state all the sorts are hardier than when their growth is completed. But especially hardy, when planted out from sowings made late in August, are *Nonpariel Improved*, *Enfield Market*, and *Fearnought*: these are true cabbages. Amongst the intermediate forms, partaking more or less of the characters of the Brussels sprouts and the cabbage, we must give first place to the *Dalmeny Sprouts* and the *Albert Sprouts*, which were a few years since introduced to public notice by Messrs. Stuart and Mein. These have passed through the frosts of 1867 with but little harm, while other sorts fully grown and on the same plots of ground have been destroyed entirely. The true *Cottager's Kale*, sent out a few years since by Mr. Turner, has proved to be one of the most valuable winter greens known. Another excellent variety, for which we are indebted to Messrs. Stuart and Mein, is the *Feather-stemmed Savoy*. This, like the *Dalmeny* and the *Albert Sprouts*, is a hybrid, and the result of carefully crossing with the Brussels sprouts.

To provide for autumn supplies, when peas and beans and other summer vegetables are gone, there should be a few small sowings of the small-growing kinds made during March, April, and May. But very early in April a beginning should be made in the sowing of the large-growing varieties of late autumn and winter greens. All the sprouting greens require a long period and a good soil to acquire perfection in time to be of use, but it would be well to sow a few small patches of these for succession in May, with a view to the month of March following, when green vegetables will be scarce. In the far north it is found desirable to make sowings of winter greens in frames about the middle of March, in order to have them forward enough to take fullest advantage of their comparatively short summer, but in southern and midland districts there is no need for such haste. At the beginning of April is early enough; and when the work is once begun it must be carried on with spirit, and there must be no starving in seed-beds until the summer is half gone. Let the stuff be planted out early in well prepared and abundantly manured soil, and the labour bestowed will be well repaid by the greater abundance and superior quality of the produce.

Looking once more to the months of February, March, and April, we repeat that the hardier kinds of cabbage should be sown pretty plentifully in July and August, and be got out on clean land as soon as they are large enough to handle; and thence to the end of the year, and indeed throughout the winter, while weather permits, there may yet be some to plant, and always some to use. Bunch greens are now realizing 6s. per dozen bunches in Covent Garden market, a capital price for those farsighted growers who made preparations for the supply in July and August last.

LIVE FOR SOMETHING.—Thousands of men breathe, move, and live, pass off the stage of life, and are heard of no more. Why? None were blessed by them; none could point to them as the means of their redemption; not a line they wrote, not a word they spoke, could be recalled, and so they perished; their light went out in darkness, and they were not remembered more than the insects of yesterday. Will you thus live and die? O man, immortal, live for something. Do good, and leave behind you a monument of virtue that the storms of time can never destroy. Write your name by kindness, love, and mercy, on the hearts of thousands you come in contact with year by year, and you will never be forgotten. No; your name, your deeds, will be as legible on the hearts you leave behind as the stars on the brow of evening. Good deeds will shine as brightly on the earth as the stars of heaven.—*Dr. Chalmers*.

ROYAL BOTANIC SOCIETY.

FIRST SPRING SHOW, MARCH 23.

The season of Flower Shows has opened auspiciously, though the elements have been most unkind. If ever an exhibition deserved good weather, and an appreciative crowd of spectators, it was that held at Regent's Park on Saturday last, when the wind changed from east to west, and in place of snow and frost, to which one had become painfully accustomed, gave drizzle instead. The contrast between the gay conservatory and the dull garden without was far greater than usually occurs on the 23rd of March, when in average seasons there is much new leafage visible, and sometimes a fair sprinkling of flowers. Whether we have any right to complain of the weather is a question; it is very certain that the horticulturists who contributed to this beautiful display deserve the highest praise for their skill, taste, public spirit, and disregard of many circumstances unfavourable to the opening of the season. The usual small tent was put up and in part occupied, but the exhibition was really held in the conservatory, which is admirably adapted for the purpose up to a certain moment, and that is when the tide of visitors is at its highest, when the place becomes inconveniently hot and crowded. All round the building were banks of plants and flowers, and across the centre was a double stage, one side of which was wholly occupied by Mr. William Paul, with hyacinths, tulips, and narcissus, and the other side with pot-roses from the same exhibitor. These two banks, and a great batch of Cyclamen persicum, were the principal features of the display; but in the tent there were eleven boxes of cut roses, from Messrs. Paul and Son and Mr. William Paul, a display of miscellaneous plants, a fine lot of fruit, and some interesting miscellanies.

HYACINTHS, TULIPS, AND OTHER BULBOUS FLOWERS.—We must be always on our guard against that stereotyped form of speech on the occasion of a surprise, in which we declare we have never seen the like before. We might say of Mr. William Paul's hyacinths that they surpassed all former exhibitions of the same kind; but perhaps that would not be true, and we have no record of measurements of spikes and travels to afford a standard for comparison. So, avoiding all possible extravagance of language, I shall affirm that these hyacinths appeared to me to surpass by some sensible degrees all hyacinths hitherto shown in my time, and they establish for Mr. Paul the fame that properly belongs to a man who takes first rank in an important branch of horticulture. It is in a good competition that one can best judge of the merits of such productions; and there they stood apart from all others by their noble excellence, though competing with them were several superb collections. One of the best of the secondary groups was a grand twelve from Mr. Kirtland, of Albion Nursery, Stock Newington. Other groups came from Mr. W. Cutbush, junior, of Barnet; M. G. Wheeler, of Regent's Park; and Mr. Bartlett, of Hammersmith. Conspicuous amongst these, both by their fine qualities and distinct colours, were the following: Princess Mary of Cambridge, Charles Dickens, Van Speyke, Vunxhaak, Sir Henry Havelock, Grandeur à Merveille, Feruck Khan, Blondin, Baron Von Tuyl, Koh-i-noor (the samples of this were well coloured), Snowball, Mont Blanc, Grand Lilas, Queen of the Netherlands, Ida (the best yellow, and very good this season), Princess Helena (a fine white), Orondates, Mimosa, Hady, Duc de Malakoff, Macaulay, Robert Seiger, Lady Sale (the last two remarkably rich in colour), Florence Nightingale, Von Seiller, La Grandesse, La Dame du Lac (superb when it has been out some time), Solfaterre, Lord Wellington, Norma, Alba supersissima (one of the best whites, and not much known), Blocksberg, Reine Blanche, Honneur d'Overveen. Tulips were largely and finely shown by Mr. Paul, and there were contributions from Mr. Kirtland, who was 1st in the class for eighteen, Mr. Cutbush, of Barnet, 2nd eighteen, and Mr. Burley, of Albert Nursery, Pembridge Place, Bayswater. The last-named exhibitor had in his collection some new varieties of considerable merit, and about which some remarks will be made shortly. Very conspicuous in the collection of tulips were the following: Vermilion Brilliant, Thomas Moore, Archduch d'Autriche, Couleur Cardinal, Bride of Haarlem, Canary Brd, White and Yellow Pottebakker, Duchesse de Parma, Jagt Van Delft, La Majestueuse, Molière, Proserpine, Queen of Violets, Queen Victoria, Brutus, Drapeau de France, Golden Prince, La Laitière, Luna, Paul Moreelse, Imperator Rubrorum. All the foregoing are good in form and habit, and eminently effective in colouring. As for the doubles, very few of course were shown; the fact is, they are not fit for show, but nevertheless are tremendously showy. The best were yellow and red Tournsol and double Duc Van Tol. In Mr. Paul's grand group of eighteen, the following were noticeable for their fine characters: Keizer Kroon, Vermilion Brilliant, Fabiola, Couleur Cardinal, Globe de Rigaut, White Pottebakker, Roi Pepin, Van der Neer, Proserpine. Perhaps a more select nine cannot be found in the catalogues. In the tent there was a delightful bank of Lilies of the Valley, and the usual difference of character amongst them. Mr. Wm. Paul put up a great lot, which were at once remarkable for profusion of flowers and paucity of leaves. Mr. Cutbush, of Barnet, put up a nice six, which were nearly in the style of Mr. Paul's, but rather better as to leaves, and perhaps the flowers fewer. Another half-dozen came from Mr. Todman, who never exhibits a second-rate thing. These were quite leafy, and certainly were less abundant in flowers than those from Mr. Paul and Mr. Cutbush. I did not notice the decision of the judges; but I am quite sure, if I had judged them, I should have placed Todman first in the six class, for lilies of the valley consisting of flowers only have really a starved and hink appearance; every fruss of flowers should have its half-embracing leaf to give it the charm that in this plant, is, when fully developed, without equal for grace and purity. Of course you are all aware that hard forcing will bring up the flowers before the leaves; I conclude, from the aspects of these three collections, that Mr. Paul potted his bulbs late, and made up for lost time by pushing them quickly. To force the lily of the valley requires about as much judgment as diplomatizing with King Theodora the Shiny Abyssinian, who clings to the obsolete idea that nature makes ambassadors that kings may cut their heads off. I had no time to make notes on the Narcissus, but I remember that Mr. Paul very nearly spoilt his glorious bank of flowers by putting them in the rear of the tulips, for the two classes of yellows seen from the end of the bank of hyacinths were somewhat of a muddle, and I remember also that Queen of the Yellows was the most defective of them all, and one that we shall have to grow a lot of next year for the plunging system.

ROSES.—The bank of roses from Mr. William Paul was quite on a par with his hyacinths. In taking to a new love he has not discarded an old one, though, to speak the sober truth, there is no such thing as an old

love, for while love lasts the subjects and objects of it are ever new and ever young. Witness these roses; why, they were worth seeing for their foliage, to say nothing of the flowers. They were, in fact, as good examples of forcing as I can call to mind in connection with exhibitions any time for fifteen years past; for what a season has this been! The following were amongst them: Niphotos, Parmentier, Maurice Bernardin, Celine Forestier (colour this time primrose and buff), Alba Rosea, Achille Gonod, Le Rhone (very fine and admirably done), Maréchal Niel (pale primrose), Dr. Andry, President, Sénateur Vaisse, Elizabeth Vigneron (one of the most effective in the group), Rev. H. Dombraïn (not out, and looking as if forcing was not good for it), *Cœur de Léon* (extra fine, and being new worth special notice for its bold appearance and fine quality; in shape it is first-rate, and as double as need be; the colour is crimson, shaded with purple approximating to magenta colour; the foliage is wax-like, dark green, large and handsome), Madame Villermoz, Madame Damaizin, Madame de Stella, Madame Victor Verdier, Glory of Waltham, Madame Herman Stenger, Kate-Hausberg, Madame Alfred de Rougemont (not quite out), Paul de la Meilleray, Comtesse Ouvaroff, Souvenir d'un Ami, Marguerite St. Amand (not quite out).

MISCELLANEOUS FLOWERS.—There were some fine specimen azaleas, camellias, and other hard-wooded plants; but the most attractive feature after hyacinths, tulips, and roses, was the bank of Cyclamens. And here Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, put up such a dozen as are but rarely seen. They were of all colours, from rich silky carmine to the purest white; but their grand excellences were in the richness of the leafage spreading over the sides of the pots, and the peculiar attitude of the flowers, standing up on stiff foot-stalks with peculiar distinctness and nobility. We have had Mr. Gordon's practice laid before us; we ought now to hear from Mr. Wiggins how he managed to hit the mark so wonderfully with these cyclamens. For these our able friend of Isleworth took deservedly the small silver medal. Messrs. E. G. Henderson had the bronze medal for twelve, and they exhibited also a collection according to good use and wont; Mr. Todman had the small bronze medal for a nice twelve. Close beside these was a fine lot of Primula prenitens, and there again Mr. Wiggins led the way with a glorious lot. I found that a silver crown-piece was only like a spot when put upon the face of one of these flowers, though as a rule a crown-piece is a good standard for size. The colours were pure white and deep rich crimson. The silver medal was awarded them most justly; and the exhibitor appended a card to inform all whom it might concern, that the seed was obtained of Mr. B. S. Williams. Mr. Todman put up a nice twelve, and Mr. G. Wheeler ditto. Cinerarias were scarce. Messrs. Dobson and Son, of Isleworth, put up a pretty group of eight, comprising Lady Theodore Grosvenor (the finest blue-edged flower yet shown), Duke of Cambridge, John Spencer (a fine crimson self), and Admiration. A pretty group of six Azaleas from Mr. G. Wheeler were admirable models of the style of plants amateurs should aim at obtaining for conservatory decoration: they were about two feet high and the same through, not severely trained, rich in colour, yet with some bits of green visible. The varieties were Rutherfordii, Roi Léopold, Cheloni, Admiration, Madame A. Verschaefelt, Extrane. Mr. William Paul put up twelve Camellias, all good. The names were Prince de Canino, Il 22 maize, Eximia, Archduchesse Maria, Lavinia Maggi, Vicomte de Nieupert, Ochroleuca, Belle Jeanette, Rubescens, Fimbriata, Mathotiana, Princess Clothilde. Mr. Bartlett, of Shaftesbury Road, Hammersmith, presented a beautiful group of miscellaneous plants, and some well-furnished baskets of flowers. The principal subjects were Cinerarias, Tulips, Spirea Japonica (admirably done), Kalmia latifolia, Azaleas, Deutzas, Primulas, Azalea obtusa. Mr. Cutbush, of Barnet, presented a superb group of pyramid Mignonettes with a standard mignonette in the midst. The pyramids were two feet high and about the same through at the base; the standard was two and a half feet high, and not so full of flowers as the pyramids. From the same, beautiful little trees of Prunus sinensis alba fl. pl., covered with white rosettes, and plenty of green leaves. Mr. Bull, of King's Road, Chelsea, put up a group of the very showy Imantophyllum miniatum, which deserves to be more generally diffused than it is, for it is easy to do, and makes a delightful change from the ordinary run of flowers obtainable at this time of year. From the same, an extra large and well-berried Aucuba of the common variegated sort, the tree about five feet high and as much through. Mr. B. S. Williams, of Victoria Nursery, Holloway, presented a group of noble plants, comprising Yucca aloifolia variegata, Dracæna australis latifolia, Azalea Triumphans (gorgeously rich in colour); Cordyline indivisa, Eriostemon pulchellum, Genetyllis fuchsoides, Chamærops humilis. But we are getting away from flowers now, and therefore must close the paragraph. The best specimen orchid in the show was a piece of Dendrobium from Mr. Burley, of Bayswater.

NOVELTIES were contributed in considerable numbers for so early a period of the year. Mr. B. S. Williams, of Holloway, presented *Pandanus Porteusii*: the habit of this plant is slender, the leaves are sharply serrated, and there is a row of spines on the midrib. *Amaryllis Ixion*: fine deep vermilion, with crimson streaks. *Philodendron bipinnatifidum*: the leaf small for the genus, and elegantly but less deeply cut than usual, in fact, looking much like the leaf of an aralia. *Caladium Duc Adolphe de Nassau*: the leaves small, centre dull red, with rich crimson veins; the margin green, with white spots. *Ananassa Porteusii*: the leaves elegantly striped, but inferior to the variegated pine commonly cultivated. *Odontoglossum maculatum*: a very curious flower, the petals set out like a pair of wings; the colour indeterminate yellow, with dull indeterminate brown spots at the base of the petals and on the deltoid lip. Also a new Gymnogramma, with a not very prepossessing appearance, much covered with gray meal. From Mr. W. Bull, King's Road, Chelsea, *Aralia crassifolia picta*: a fish-bone aralia, the leaves very long and narrow, and set on the stem at an angle of 45°, like the ribs of an umbrella slightly expanded; these leaves are dark green, with brown stripe up the centre, and a bright green spot at the base of every one of the triangular teeth which beset them on the edges. *Aralia spatulata*: like the last, but minus stripe and spots. *Agave macrocartha*: a good small greenhouse kind, the leaves glaucous and formidably armed. *Rogeria hybrida*: a good example of this beautiful but scarce shrub, with a pretty panicle of its pink flowers. *Phajus grandifolius, fol. var.*: a veritable variegated-leaved orchid, one of the oldest in cultivation in the newest imaginable dress: the variegation consists of bands and lines of sulphur cream in two or three shades; it is as good in respect of variegation as the variegated Aspidistra lurida. A standard male Aneuba from the same attracted the attention of practical men, causing water in the mouth to some who had counted on it twelve heads of flower-buds, only two or three of which were open: pollen enough there to fertilize a hundred

big trees if economically disposed of. *Cypripedium concolor*, *Cypripedium Dayanum*, *Cypripedium hirsutissimum*, *Cypripedium Lowii*, *Odontoglossum gloriosa*: these new and scarce orchids were well shown. We need not describe them, as it is but recently they have been before us as new plants. But for the lovely *Odontoglossum Alexandra* a word must be said. It is of miniature growth, specimens in 51 sized pots producing flowers freely, and in a batch of a dozen plants not two were alike. The two best were a pure white, the flowers of which are a trifle larger than the average, and a white with curious spots, looking as if stencilled in a most artful and pretty manner. This is pre-eminently a lady's orchid. From Messrs. E. G. Henderson and Son, St. John's Wood, examples of the new bedding plant *Pyrethrum Golden Feather*, the leafage of which is a clear sulphur-yellow shading to a sulphur green. This must prove valuable. Of course the flowers are white, and perhaps they may have to be picked off. How valuable it would be if the flowers were the same colour as the leaves, or even a gold yellow! but to hope for such a thing is foolish. From the same a few new tricolor-leaved geraniums. *Ingham Beauty* has some leaves dark green, with narrow amber-brown zigzag zone; others clear bright yellow, with green disc and zigzag zone, varying from chestnut to vermilion: the highly coloured leaves are so highly coloured that probably they have not in that respect their equals. *Timworth Pet* has a very broad chestnut and pink-red zone and yellow edge; in quality middling. *Emma Cheere* has a bright green disc, lemon-yellow edge, and a fine chestnut and vermilion zone; first rate. *Ada Mann*: small leaves, the zone wholly red, margin sulphur-colour, disc divided into rays of pale green and pale yellow. *Annie Paget*: zone varying from brightest vermilion to dull red, margin sulphur, disc barred green and sulphur. From Mr. Watson, of St. Alban's, a few tricolors. *Mrs. Dix*: yellow edge, olive and bronze zone, breaking into bold bars of clear brick-red (the red of wet bricks), the disc dull green: this is superb in every respect, the leaves round and flat, the plant compact, dwarf, and dense, covering a large extent of surface; the best new tricolor in the show. *Annie Merry*: diminutive and pretty, edge creamy, with faint wash of pink, zone varying from dark amber to fiery red, disc dull green: the young leaves are wholly sulphur-colour, with bright red zones. *Miss Watson*: a robust habited plant, apparently not shown in proper condition, as the old leaves were pale and washy as if much the worse for the winter; the new growth superbly coloured with deep red and chestnut zone, and sulphur edge; the leaves are rather too convex to show their colours well. Messrs. Jackson and Son, of Kingston, sent a new *Cattleya*, with flowers of a clear lilac blush, the lip tipped clear buff; the plant has ugly elongated pseudo-bulbs. Mr. Wiggins of Isleworth had a superb *Cattleya*, with clear pale lilac sepals and petals, the lip richly coloured in front intense velvety purplish carmine. From Mr. R. Marcham, gardener to E. Oates, Esq., Hanwell, *Cineraria Madame de Bernus*, a fine, large, flat flower, with broad margin of violet-blue, shading inwards to strong rosy purple, pure white ring, and dark disc; first-rate. Also *Cineraria A. de Bernus*, a good pure purple self. From Mr. Cruikshank, gardener to J. Lloyd, Esq., Langlebury, *Verbena Beauty of Langlebury*, a very superior flower, of the striped class. The flower and truss are of good size, the ground white, each petal has a broad stripe of clear lilac. If this does not become famous in some way or other, perhaps as a better, I shall question if I know how to distinguish a good verbena from a bad one.

FRUIT.—Remark was made above on a collection of fruit in the tent. It consisted of apples and pears only, in an admirable state of preservation, and in some instances remarkable for size and colour. These came from Mr. Ford, gardener to W. E. Hubbard, Esq., St. Leonard's Lodge, Horsham. As a list of these fruits shown in good condition at this time of year must be valuable, I here present it: Of apples there were Green Pearmain, Holland Pippin, Blenheim Orange, Claygate Pearmain, Norfolk Beefing, remarkable in colour; French Crah, Ashbridge's Pine, Wadhurst Pippin very handsome; Leppard's Seedling, small, round, lemon yellow; Red Pearmain, Scarlet Nonpariel, No. 3, medium, conical, yellow, pale crimson on cheek; No. 2, neat, round, yellow streaked red; Yellow Newtown, almost egg-shaped, clear yellow; Adams's Pearmain, Farm Gardens, small, round, richly striped deep red, very showy, and well adapted for decorative purposes; Poor Man's Profit, Gilliflower, not a good sample, being under-sized, but the colour good; No. 1, a small yellow rather pretty fruit; Minchall Crah, Royal Russet, London Pippin, Ribston Pippin, so highly coloured that all the fruit-growers who caught sight of the ticket took care to handle the fruit to satisfy themselves, but they found it was the true Ribston; Hangdown, medium sized, oval, yellow, with a few red streaks; Treadcroft's Seedling, medium, round, yellow; St. Leonard's Seedling, small, dull green and dull red with much dull russet, an ugly fruit—it ought to be first-rate to the palate to make amends for its offence to the eye; Edmund Jupp, small yellow; ReINETTE Grise, Cockle Pippin, First and Last, a nice small round apple, like Scarlet Nonpariel; Forge. Of pears the sorts were March Bergamot, Easter Beurré, and Uvedale's St. Germain. Though it is not the rule to class potatoes with fruits, we may do so for once, and add here that Mr. Ford showed good samples of Ford's Red Robin, a good white-fleshed late-keeping potato; Pink Eye Kidney, Late Red, very ugly, keeps well; Prince of Wales, a good productive potato; Maiden's Blush, large irregular semi-kidney, the colour drab, with bars and patches of pale red; Red Regent, a bad-flavoured but highly productive sort. S. H.

MESSRS. CUTBUSH & SON'S EXHIBITION OF SPRING FLOWERS IN THE CRYSTAL PALACE.

Messrs. Cutbush and Son, of the Highgate Nurseries, are repeating the experiment of last year by an exhibition of spring flowers in the Crystal Palace. And a very pretty exhibition this is, occupying the northern end of the nave beyond the great orchestra, where a long table, divided by a green baize partition, is occupied on one side with hyacinths and tulips, and on the other with a mixture of all the most attractive subjects proper to the season. We shall present some collective notes on hyacinths and tulips shortly, the result of recent inspections at various exhibitions; so for the present we may say that Messrs. Cutbush ably sustain their well-earned fame as cultivators of the hyacinth in the display at the Crystal Palace. Lovers of this flower will find it an agreeable pastime to visit the Palace early in the day, and make up their books for next autumn's purchases according to their own likings and estimates of merit. The exhibition will continue till April 6th (Saturday next), and there is therefore plenty of time at command for it. Now we beg of those of our readers who pay a visit to this exhibition to notice the great difference between the two sides of the long table. Take the hyacinth side

first; it is charming. There are fine spikes, fine colours: all are as fresh as if carved out of auroras and the splendour of dying dolphins (you know the fable). Now go to the other side, and the mixture beats the hyacinths as effectually as a bird of paradise in beauty beats a London sparrow. How is it? The answer is *variety*, which should be sung in the style of Herr von Joel. In the mixture there are azaleas, dielytras, cyclamens, cyclamens, deutzias, camellias, primulas, Gammet pelargoniums, heaths, epacrises, roses, violets, narcissus—everything in fact that can be thought of in connection with spring flowers, with the exception of tree peonies and crown imperials; and these last are fine things for pots, as could be proved in a certain garden at the present moment. The two sides of the table are as different as they can be, and rightly so; but the difference is all in favour of the mixture, which offers a new charm at every step, whereas the hyacinths and tulips, with all their beauty, pall by their sameness before we can traverse their length. Judge for yourselves, friends, and learn therefrom how to arrange a show, and how to decorate a conservatory. S. H.

CALLS AT NURSERIES.

MR. B. S. WILLIAMS'S, HOLLOWAY.—The great conservatory is now very gay with azaleas, deutzias, hyacinths, early tulips, and other spring flowers. One advantage of a call at this nursery is that we cannot fail to become convinced that noble forms of vegetation have far higher claims on our regard than plants destitute of beauty of form, however splendid their colours. Compare a hyacinth with a palm, for example; but let it pass for no one can do it. Let it suffice that the bits of colour used in this beautiful house show with tenfold effect as illuminating agents to palms, ferns, cycads, and dracenas, of which there are here some glorious examples. In the orchid houses several good things are in bloom, and the fern houses offer a few nuts to crack to ardent petridologists.

MR. JOHN FRASER'S, LEA-BRIDGE ROAD.—The show-house is delightfully fresh and fragrant with heaths, epacrises, camellias, azaleas, hyacinths, primulas, and other spring flowers, judiciously mixed with fine foliage plants and little lively batches of such things as Tetrathecas, Chorozemas, Hedaromas, Leschenbaultias, and other hard-wooded plants that are in constant demand. In the houses devoted to forced roses there are fine blooms of President, Maréchal Niel, Souvenir d'un Ami, Canary, Niphotos, and many of the highly-coloured hybrid perennials.

MR. OUBRIDGE'S, STOKE NEWINGTON.—Enormous stocks of bulbs have lately been cleared out from the houses and pits, and the celebrated house of gauntlets, which have been supplying myriads of cut flowers since October last, is now quite gay with colour. Cinerarias are here well done, as are also fuchsias, deutzias, camellias, and all the round of popular bedders. A number of Ghent azaleas have been forced this season, and have turned out remarkably well, their colours being most acceptable to contrast with the prevailing colours of Azalea Indica, and of camellias, &c.

MESSRS. E. G. HENDERSON AND SON, ST. JOHN'S WOOD.—The great collection of hardy herbaceous plants, comprising some six thousand species and varieties, is now recovering from the deadness of its winter aspect, and offers us many of the bright colours of spring. A considerable number of good things are in flower, and collectors may quickly determine what are the best subjects for a good display in the months of March and April. There is here a good collection of Aquilegias, which are as the humming-birds of the flower world, so beautiful that it is absurd to attempt to describe them. Let the visitor ask for *A.erulea* or *A.spectabilis*, and then judge if any man ought to dare attempt to describe them. In the houses you may find everything from the rarest orchid to sixpenny bedding plants, and in the majority of instances more stock than there would appear to be any market for; but there is a market, and the cartloads that go out explain the vast activity within. The glory of the place is the tricolor geranium house. It is a favour to be admitted to this, and visitors desirous of entry must ask at the office for permission. Whether permission is worth seeking may be best considered after a careful perusal of the "Arabian Nights;" for all the pavements of gems and gorgeous designs in mosaic and jewellery therein described or alluded to are outdone in the leaves of the tricolors. Go and see, and having seen, believe. S. H.

COTTAGE GARDEN EXHIBITIONS.

Vegetable and flower shows for the poor are by no means uncommon in this country, and there can be no doubt if they were still more general, and more generously patronised by the wealthy, they would do much towards improving both morally and intellectually the condition of the artisan and the agricultural labourer. However, so satisfied am I, from what I have seen of the working of such institutions, that it would do so, that I cannot let an opportunity which now presents itself pass by without giving my testimony in favour of their more general adoption, whether in populous manufacturing towns or those smaller towns, villages, and hamlets that are more favourably situated for carrying on the work of a garden. In every case a suitable set of rules is easily compiled by those who are acquainted with the local requirements of the place and the people; and in respect of other matters, there are few preliminary difficulties. In any district where there is anything like a labouring population, the thing is to be done, if a few intelligent gardeners can be induced to undertake the task, with the sanction and support of their employers, the clergy, and such other persons of influence as can be induced to help. There is no reason why every small town should not have its annual show; and the combination of two or three (or more) adjoining villages might do the same. Under circumstances similar to the last it was, when holding a situation in the county of Sussex, that I was called upon by my then worthy and now lamented employer to take an active part in the management of a cottagers' show, and the impressions of utility it made upon my mind have never left me. Supported as we were by a generous public, and a perfect unanimity of opinion amongst the workers, we lived to see our efforts to do good appreciated both by those who supported us and those for whose benefit we laboured.

But my object now is to give the reader the benefit of my experience, as gathered from having taken a part in the management of a cottagers' show. Not that I have much to relate, but what little I know may be the means of preventing others from committing mistakes generally made when inexperienced people set to work without anything to guide them. And first let me say, in framing a set of rules, do not be guided in any way by the rules of another society; the only safe guide is to frame them according to local circumstances and influences, as what may be applicable

in one instance will be totally unsuitable in another. Take as an instance two of the villages in the county in which I laboured, under the famous Southdown Hills. Many of the cottagers living close under the hills could compete in the point of earliness with a nobleman's walled garden, when those living a mile or two miles farther out from the hills would be quite a fortnight later, and consequently would have no chance when competing by the side of their neighbours. The cottagers knew all about this, and until a provision was made for those favoured by their sheltered position apart from the others there was a general discontent. The cottagers of the late districts complained that they were not fairly dealt with; that as regards the competition there was nothing to stimulate them to take a pride in the produce of their gardens, and there was a gradual falling off of entries, until the two districts had distinct classes to exhibit in. I have merely mentioned this circumstance to support me in the assertion, that it is unwise to be guided by the rules of any other society, and similar circumstances will very possibly happen to other places, if not in the same way, in some other details. Care too should be exercised in awarding prizes to such subjects as are most generally grown in the neighbourhood, not forgetting that they should be useful subjects either for sale or for the consumption of the cottager's family; and prizes should be only given to such vegetables as may be considered in season in a cottager's garden. For instance, the offering of prizes for celery in June is a mistake. The offering of such unseasonable prizes is all very well if you want to try the skill of the exhibitors; but my idea is that they should devote their time and skill to the production of more profitable subjects, that would be likely to fill the pot and assuage the hunger of a toiling family. Not that I would deprive even the common labourer of such relishable subjects; but I do not like to see them devoting time to crops that are not necessary for their own table, or that are out of season; for the time and manure, &c., spent in growing a bit of early celery for a show would suffice to produce a sack of good potatoes. In framing rules, specific information should be given as to quantities and numbers. Such terms as "dish of peas," and "bunch of turnips," are too vague for the comprehension of the majority of cottagers; and if they have nothing to refer to to guide them, the chances are that on the morning of the show the committee will find they are glutted with double the quantity required to enable the judges to form their opinions. It is also very essential to state distinctly whether the roots of such vegetables as carrots and turnips should be washed previous to being shown, or the neglect of this will probably cause a disfigurement in the various lots, as some will bring them cleanly washed and trimmed, while others do neither. As a matter of course, I am in favour of washing—in fact, in favour of showing everything clean and perfect, so that it can be handled by the judges, and be seen by the visitors in its true colour as if already on the table.

From what I have learnt from personal contact with the subject, as regards the amount to be given in prizes, I feel satisfied that it is not strictly necessary for the good of the cause to give high prizes at all; I would rather increase the number, as a couple of pounds distributed in six prizes will give more satisfaction to the majority of exhibitors (for whom alone we labour) than when only divided into four. In this matter I am partly assuming that the funds at disposal are not large, which unfortunately is too often the case. But as a point to better illustrate my meaning, I will say that we have £2 to devote to early kidney potatoes. Now the satisfaction amongst those who exhibit will be greater if there are six prize-takers instead of four, even if the lowest should only get half-a-crown. The same remarks will apply to such things as cabbage, peas, and beans, in fact, to anything that is universally grown in the cottager's garden. It is simply absurd to commend anything or any one of them; they don't understand commendations unless they are explained and illustrated by the coin of the realm, or something equivalent thereto.

In offering a piece of advice to those who may be called upon to act as judges at these shows, I hope I shall not be thought presumptuous, as the remark I have to make might at least be useful to some one. It is this: in certain classes, such as potatoes for instance, where there are, or ought to be, six prizes at their disposal, and competition rather strong, there is no better way to overcome any difficulty that may arise as to the best than to fix a certain figure as the standard, say ten. Well, ten being the standard, that number should be placed upon the best lot, and the next best should be nine, and so on through the whole lot, affixing the figure to each, until all the prizes are awarded. After trying various means to make the work of judging as simple as possible, I have found this the best.

An important matter in connection with cottagers' shows is the giving of prizes for the best cultivated gardens. This is an essential feature in all country places, but very few, if any, that have not taken part in their management can understand its correct value. Having seen the beneficial effect of the annual inspection, and the industrious habits it creates, and the sort of manly pride it engenders in the minds of those who enter the list of competitors, I can speak of its utility with the greatest confidence, to say nothing of the pleasure with which I used to look forward to and enjoy it when going with a neighbour the yearly round of inspection. It was a pleasure to visit these honest country people, and to listen to minute details of how this crop had succeeded beyond their expectations, and how they had failed in another direction notwithstanding the care they had bestowed, and how they found ample amusement in their gardens on moonlight nights, which formerly they used to spend at the beerhouse. Not infrequently such conversations would lead them to detail their sorrows and their pleasures as connected with their every-day life, and when a willing ear is given, and some interest shown in their welfare, it is astonishing how soon confidence is inspired, and a degree of truthful innocence shown, that can only be met with where the general class of inhabitants do not mix up with the more advanced portion of the world. But be it remembered, to secure their confidence they must know something of you and your whereabouts, or they will be found about the most reserved class of people upon this earth. This shows, then, that if any attempt is made to improve the condition of the English labourer (or rather, I ought to say, the agricultural part of them), the first step should be to win their confidence and to learn from them their views of their lot in life, and their relations to things and persons around them. This done, and a willingness displayed on the part of those whose duty it should be to assist them, as a proof that they are in earnest, we shall find that the agricultural labourer is not exactly so stolid and unimpressible a being as the public are taught to regard him. Nay, some acquaintance with the class will enable us to single out many a bright example of intellectual skill, combined with a strong mind, industrious habits, and the strict observance of a pure morality. Such men as those I have heard complain bitterly of the

agricultural labourer being considered low in the scale of social life, and well they may, for whoever speaks to them assumes a tone that must be painful to an independent mind. That there are some of an opposite turn of mind I do not pretend to deny, but I have never yet met with any class of men, of whatever calling, but there were some black sheep amongst them.

To improve the condition of the agricultural labourer, the establishment of cottagers' shows is a step in the right direction. But there are certain individuals who are dissatisfied because they do not effect at once a complete reformation in the habits of all those for whose benefit they are intended. But that is expecting too much, especially when we consider the small amount of influence brought to bear upon the work. For remember, the sum of fifteen shillings or a pound, which is the highest prize generally given for the best kept garden, is not much to induce a man to give up old practices and associates. In my estimation, it is good work if only a few can be induced to do so, and the example of these few will do a great deal of good in the conduct of others, if only a moderate amount of patience is exercised, and time given for them to learn the advantages that are to be derived by following in the footsteps of those who set them a good example. But my space is running out, and I must proceed to more practical details that yet remain to be spoken of.

I would enlist the reader's attention while I advocate that both cut flowers and plants in pots should be added to vegetables and roots, and liberal prizes given, as plants and flowers constitute a grand feature in a cottagers' show. The amount of jocular rivalry exhibited amongst the fair sex is somewhat amusing at these shows, as the words "I will beat you next year" are often heard amongst them. It was a feature of the rules of the society I have above alluded to, that when inspecting the gardens we were also to inspect the lower rooms of the different cottages comprised in the competition. This proved to be of some assistance in determining the real merits of the case, as it gave the inspectors an opportunity to judge of the habits of both man and wife; and generally speaking, where there was a well-kept garden the house was equally well ordered, and in many cases scrupulously clean, an allowance always being made where there was a young family. We can all understand the humanizing influence of a clean well-ordered cottage when a man returns from his daily labour—how it gives a fresh stimulus to increased activity, and makes him doubly anxious that nothing on his part should be wanting to maintain the same harmony of action. Understanding this, then, is it not surprising that more extended efforts are not made to see these men better housed and altogether better paid? No wonder that in every county there is a scarcity of farm labourers; and this state of things must last until dire necessity compels the employers to check the continual stream of young men who are leaving the plough and the sickle because the wages are not sufficient to induce them to stay. There is much, very much, to be done to improve the moral and social condition of these people, by instituting societies similar to that I am now advocating. But all those who make an effort to do so should remember that they are Englishmen, and therefore very susceptible of being driven to undertake anything that does not bear upon the face of it pretty strong evidence that it will ultimately be the means of benefiting them. Therefore, in any attempt that is made to assist them, they should be given to understand for whose benefit the thing is started, and he left to take their own course of action; for the better informed amongst them will undoubtedly embrace it. Seeing this, the less hopeful ones will soon follow, and as they begin to understand its purpose they will appreciate in a grateful manner all that is done for them.

Such is my experience of the working of a cottagers' society, and if these remarks should prove interesting to only a few readers, I shall be abundantly rewarded, as it is a subject about which I feel some interest.

J. C. CLARKE.

VENTILATION OF VINERY BORDERS.

The instructions usually given for the formation of vinery borders never include the means of providing a supply of pure air to the roots. You will not find one vinery in fifty with any provision whatever made for an element so essential in producing richly coloured, highly flavoured fruit; and as the mode of applying it is extremely simple, let me attempt to explain a cheap plan for the consideration of any of your readers who may be altering their borders or forming new ones. I will suppose that the space has been excavated to the required depth, and, as the first thing to be attended to in our uncertain climate, drained in the most thorough manner. Whether hotted with concrete or not, before any stones are put down, let 4-inch fireclay pipes (or anything better about their diameter) be placed upright close to the outer edge along the front of the border, say at distances of 5 ft., fitting into others with a "knee" or bend. With the latter will be connected common field pipes, running towards the vinery, and at right angles from the joints over the whole border, communicating with the interior border of the house, through which bring up neat pipes to correspond with those in front outside. The upright ones (outside and in) should project slightly above the level of the border, and be fitted with valves or a simple cap, to be opened or shut at pleasure. If done in this way the cost is very trifling. A bed of clean stones broken small is next laid down, then the previously prepared soil, and the border is complete. With such a simple contrivance an abundant supply of pure air can as often as required be furnished to the roots, a thing as necessary to the health of fruit-bearing plants as water itself. But beside this, when the sun shines and the upper sashes of the houses are opened, in two minutes the caps are taken off, and a gentle stream of warm air passes at once under all parts of the border. Before sunset the whole are again shut, and the heat thus imparted to the soil is kept there, thus raising the temperature of the border by ten or twelve degrees for whole months together. Of the effects on vines, peaches, and figs I saw the best possible proof last season at a place in the south of Scotland, where with ordinary care and attention, Muscats and other fine grapes are grown, as I was informed, "as easily as potatoes;" and certainly for regularity, size of bunch and berry, and delicious flavour, the heavy crops there were matchless. The intelligent head of the establishment just remarked, "there is no secret about it; utilize what Providence provides, and let every grower of grapes take advantage of this by a thoroughly ventilated border."—*Field*.

The literary style of asking for a slice of ham at dinner is, "I'll thank you for an elegant extract from Bacon." The author has been exiled to Ham, and wishes he had, by silence, saved his bacon.

COLLECTING AND SELECTING.

Amateur cultivators, who are not bound hand and foot to the delusions of the bedding system, find exhaustless amusement in collecting representatives of various families of plants adapted to the means at their command for keeping and cultivating them. Where the bedding system reigns in its full severity, this is impossible, for greenhouses, frames, and nursery beds are all filled to overflowing with the monotonous round of subjects that are to be planted in May, that are to bloom in July, that are to be ragged in September, and that are to be housed in October, leaving the places they occupied empty and cold till May returns again. Collecting allies horticultural recreation with botanical science, affords scope for the exercise of thought, and occasionally quickens inquiry and research; it instils into the mind a larger knowledge, and into the heart a warmer love of plants than is possible where the garden is kept as a place for a mere display of colour during three or four months of the whole year. It is next to impossible to avoid collecting when an interest has been created for certain forms of vegetation. The lover of ferns is always in want of certain species and varieties; the cultivator of succulents, of bulbs, of hardy herbaceous plants, of choice trees and shrubs, finds that his possessions are so many keys to the vegetable kingdom, and at every advance of knowledge accomplished by their aid, he learns how many more interesting and beautiful plants there are in the world which he has not yet obtained, and which he would rejoice to possess. Collecting is, in fact, an exciting pursuit, and we could sooner forgive a man for wasting his substance in riotous gardening, when this passion had seized him, than if he were under a geranium or verberna spell, revolving only amid half-a-dozen species of plants, and deriving no higher pleasure from his garden than repeating upon its surface the designs he is already tired of in carpets, chintzes, and wall-papers. For the public promenade, as for the great garden, where there is room for everything, and ample means to boot, good bedding is one of the necessities of the decorative part of horticulture; but in the small garden, which is like an extension of the drawing-room, or a sort of outdoor parlour, something more is wanted than daubs of yellow and red, which,

"Like the borealis race,
Flit ere you can point their place."

We want entertainment the whole year round, beauty for the eye, and with it fragrance, agreeable associations, variety, and something to engage and interest the mental faculty. In place of the scrubby evergreens that are tolerated—because the bedding, like the Dragon of Wantley, swallows up everything but itself—we ought to see in private gardens a considerable variety of the most beautiful shrubs and trees, deciduous and evergreen; the first so various in form and leafage, and many of them so magnificent when in flower; the second warm and rich in the depth of winter, making the place look like home, so that a glance from the windows neither chills nor repels, as must be the case when a person of any taste looks out upon a dreary parterre that is known to be of use only in the height of summer, when mere colour is least wanted, and when, in many cases, the family are away, and see nothing of it. And in the borders in advance of the trees and shrubs we should see mixtures of all kinds, spring flowers in abundance, and in all the delightful variety in which they may be obtained, the gems of the vegetable creation that appeal to the pleasantest memories, and in their subdued and refined colorings seem to be almost musical in their speaking prettiness. And for summer and autumn, and even for winter, the hardy plants comprise myriads of fine subjects, some showy enough even for a vulgar taste, but many more beautiful in the true sense of the word, with grace of form and delicate harmonies of tintings, and characters so individual, that every one deserves to have a history, and to have that history told to all admirers. And when winter comes again, the variegated-leaved and berry-bearing shrubs that are within the reach of English cultivators would suffice to effect an apparent change of climate. It is enough for us to be frozen to-day and roasted to-morrow in this wayward, changeable, ungenial, unfriendly clime; we need not make our gardens lugubrious to increase the horror; yet this we do, and only at rare intervals do we meet with examples of what English gardens might be in warmth, cheerfulness, richness, and variety, even in the very depth of such winters as make havoc of human lives. Our ten years' repetitions of such arguments as these may, for all we know, have somewhere produced an effect by this time; but whether there be results or not, we shall probably continue, as occasions offer, to direct the attention of our readers to the undeveloped resources of ornamental gardening in this country, and do our best to point out the several subjects that are best fitted to make our gardens worthy of the spirit and the means and intelligence of the English people.

We begun with remarks for collecting, yet we should hope that very few of our readers are devoted to the profitless task of indiscriminate gathering together of the members of any family of plants. It is not every member of the vegetable kingdom that is adapted for cultivation in gardens, and amongst the most beautiful and useful species and varieties some are better than others, and the wise man will, if possible, select the best and leave the rest to nature. As for ugly plants—and there are such—they are generally relegated to the botanists, which is a form of sarcasm founded on the too often professed admiration of would-be botanists for things that persons of taste find nothing in to admire. Far better than collecting is selecting, and in this amusement we are constantly endeavouring to assist our readers, by directing attention to the best species and varieties in the several classes of plants that are adapted for the embellishment of our gardens. Hardy plants would never perhaps have been at a discount, as they have been for many years past, if cultivators of them had taken care to sift out the best and toss the rest to limbo. No one, for example, amongst the uninitiated, would care to grow Michaelmas daisies, after having seen an ordinary mixture of them in an old-fashioned border, for a considerable proportion of the immense number of species entered in the books are rubbish, their ragged weedy look is completely matched by their miserable flowers; so of many other families, yet the true collector can pick out a few that perhaps are unparalleled for beauty, and if amateurs would grow only what is good, they might serve the cause of art in this direction; for good herbaceous plants, and indeed good shrubs, good bedders, recommend themselves when seen, and bring into good repute the classes they belong to. Those who grow ugly plants do harm to horticulture, and the very many ugly things that have been tolerated and that are tolerated in English gardens make it appear to the passing crowd that in geraniums, calceolarias, and verbenas alone are beauty and interest to be found.—*Floral World.*

AMONG THE TOMBS.

I have had a thorough treat this afternoon. Have you? What, have you been to a flower-show? No. Have you had a long ride with the missus, ay? No! Had a botanizing stroll along the hedges and ditches somewhere? No! Well, come then, Chitty, tell us what it is. Very well, I will in as few words as I can. I took the 1.13 train from Ludgate Hill to Bromley, expecting when I got there to find a conveyance to take me on to Knockholt. Not finding the conveyance ready, and learning further that I should have three hours to wait before I could go on, I took a stroll into Bromley churchyard in preference to walking about the town, for there is a great resemblance among fishmongers' shops, and bakers' shops, and linen-draper's shops, and shops of all sorts, in every part of the country, and it is rare that any new feature of interest presents itself in that style. But a churchyard anywhere, especially an old churchyard in the country, has at all times many features of interest. Not the least is the certainty that from these repositories of the dead the Great Redeemer will win for Himself immeasurable glory by the reclamation from decay and destruction every human body which has here been committed to the keeping of mother earth. Then, again, one often gathers from a single sentence inscribed upon the gravestone the whole history of the life, death, and character, making it a very interesting thought that one is walking among the remains of many who have occupied important and influential positions among their fellows while living. And, to my taste, a very interesting feature, more especially in old churchyards, is that one meets with mossy lichened stones, surpassing in the beautiful arrangement of the various mosses, and the exquisite tracery of the innumerable touches (so to speak) of the first growths of lichen, anything that the most finished skill of man can produce. Well, but what has all this to do with the treat you so thoroughly enjoyed? I'll tell you. Strolling round the churchyard, among other interesting monuments, the contemplation of which gave me much pleasure, I came upon two flat stones which presented a very startling and novel appearance. The inscriptions upon these two stones were all cut in Roman letters about an inch and a half in length, and every letter upon one stone, and the upper portion of the second, was beautifully embossed with moss of the brightest and liveliest green imaginable. For some yards before I came to them, I perceived every letter clearly defined, and standing up about three-sixteenths of an inch above the surface of the stone, like so many bright green velvet cushions. These cushions are the growth of several years, as you will perceive by the dates (I enclose an exact copy of each inscription), and are most favourably situated under the dense foliage of a horse-chesnut, which completely covers them, so that in the summer time I should think they hardly ever dry up, because, in addition to the close shelter of the umbrageous foliage, a close fence runs near to them, and in consequence they are not exposed to such draughts as would wither and dry up the beauty and greenness of their exquisite colouring and outline. Fortunately, there was not a single flaw in the tracery of either of them. Some sacrilegious foot had slightly scratched the slime of the un-inscribed part of the lowest stone, but not the slightest damage had been inflicted upon the integrity of the letters. Once more, for I really cannot get these moss letters out of my eye, let me say that they were as clearly defined as though they had been shaped in a mould, and turned out plump upon the surface of the stones. They were quite unique, and gave me more real pleasure than anything of the sort I have ever looked upon.

Another very old tombstone, on the opposite side of the ground, beautifully wrought, and having a skull at each corner, was mossed on three sides with the cushion moss, the moss intruding itself into those cavities in the skulls representing the eyes, ears, &c. The fourth side was nearly covered with sphagnum, the upper growths of which resembled miniature groups of Lombardy poplars, pushing their way upwards, and promising in a few years to occupy every portion of the surface. Isn't it a pity that you are banishing such sources of interest from your churchyards in the city of London? I entirely endorse the sentiments of "Passer-by," inserted in your widely circulated and useful magazine some time since, and I hope they will not be without their use, in connection with some similar remarks I have seen in the leading journal, in staying the progress of such abominable desecration.

MATTHEW THOMSON, ESQ.,
Of Maningham Lodge,
Yorkshire.
Died at Hastings, the 23rd
Day of September, 1847,
In the sixty-seventh
Year of his age,
And was buried beneath this stone.

ELIZABETH SARAH,
Widow of Matthew Thomson,
And daughter of the
Rev. William and Mary Atkinson,
Of Thorparch, Yorkshire.
Died in Dorset Place, London,
The 20th of June, 1859,
And was buried here.

Sacred
To the memory of
THOMAS CAREY PALMER,
Of Clay Hill, Beckenham,
And late of this Parish.
He died 24th of March, 1835,
Aged 57.
And of
ELIZABETH REBECCA PALMER,
His wife.
She died 9th February, 1856,
Aged 74.

The latter part of this inscription was not filled up cushion fashion, not having been cut so long as the first part, there has not been sufficient time; but every letter was beautifully inlaid with a perfect covering of the loveliest green, and if undisturbed will in a few more years present the same embossed appearance as the first part.

WILLIAM CHITTY.

ROSES AND ROSES.—No. IV.

I promised my friend to say a few words about some pot-roses he saw in my place two years ago, and which were brought forward in the "plunging system," and made a very beautiful display some time in advance of the flowering of roses in the open ground. Before I have done with roses this season, I hope to say something about pot-culture in general; but I intend now only to speak of these roses in particular. Two years previous to the said roses being potted, they were budded on short briars in a nursery piece, and were regularly pinched in their early growth, after the same rule that we pinch pear-trees, &c. As they were in strong soil, and the briars were young and established, they made a very great growth the first season. The next year they required but little pruning. They were in fact only slightly shortened in; but again they were pinched several times during the season. We used to go into the piece, and while a man worked with the fork to prick the ground over and throw out weeds, I went on with a knife to cut out suckers, and slightly shorten in strong growths, and pinch out flower-buds to get shoots instead. In the autumn of that year the best proportioned were taken up carefully, and potted in a mixture consisting of the top crust (crumbs) of a great heap of clay, good turfy loam, and hotbed manure not quite rotted to powder—rather fat in fact. The roots were slightly shortened, and the heads trimmed a little, but not hard pruned; and they were potted in pots of 8, 9, and 10 inches diameter, according to their size; and sometimes, owing to the roots being (nursery fashion) one-sided, we had to put the stems close to the sides of the pots. Well, they were all plunged to the rim in a bed of leaves, and taken very little notice of till the middle of April the next year. Then a great bed of long dung was made up *in the open air*; the bed two feet deep in a sheltered spot, in fact on the south side of an old hedge, consisting of plum, privet, and a mixture of such stuff, about fifteen feet high. When the bed was nicely warm, but at what precise temperature I cannot say (perhaps 60°), the pots were plunged in it nearly to their rims, and every night a few cans of water were plunged as well, and out of these cans those that wanted water were supplied next morning. They were never searched for maggot, they were never washed or dusted for fly, they were bright as new waxwork from the first leaves they pushed, and the young wood came thick as lead-pencils, with thumping flower-buds in plenty. As soon as the buds were showing fairly we began to help them with guano, but in a very rough way. I used to take a little out of the bag, and put about a tablespoonful into a two-gallon can every night when the cans were filled and placed on the plunge-bed. As soon as a few flowers were open the guano was discontinued, but plenty of water was given, and a few of the rather wiry-growing kinds were assisted by means of twigs and ties to carry their blooms nicely, but as a rule they held their flowers nobly, and took care of themselves. A few frosts occurred late in the season, but they were untouched; the hedge sheltered them, and the constantly-escaping warmth of the bed preserved about them a genial atmosphere. At the end of May there was a good show of flowers, and the bed was cold. They were then transferred to a sheltered fore-court, where a display of some sort is always required, and were there plunged to the rim; and they flowered freely till the end of June, and were then beginning to lose their looks through being under the shade of trees.

The next process consisted in removing them back to the plunge-bed, but before they were placed upon it they were slightly pruned and pinched, then plunged as before, without the aid of artificial heat, but with all the assistance of a cool and constantly-moist condition of their roots. Now guano was used again, and as fast as flower-buds appeared they were nipped out. By the end of September they were quite at rest, and were lifted out, and only just in time to prevent a second growth, for the roots were pushing into the plunge material, and a warm autumn would have renewed their activities. They were now carefully pruned with a view to the formation of handsome round heads. They were next shaken out, the roots moderately shortened in and repotted—some in the same pots they came out of, some in pots a size larger, and in every case an endeavour was made to get the stems in the centre, as they were now to be considered pot roses in the properest sense of the word. They were housed in a cool, clean, light pit, were fully exposed to the weather till Christmas, and were then placed in a large light pit on a bed of warm leaves, and they began to push nicely. About the middle of February they were placed in a

Pot Rose Coupe d'Hebé.

house with a low-span roof, the pots standing on a wooden floor over which was strewed a couple of inches of rotten hops. A service of 4-inch pipes kept this house at an average of 45° by night and 50° to 60° by day, according to weather. Very little air was given for some time, but as the season advanced air was admitted freely on fine days. A temperature of 70° was allowed sometimes, when the wind was in the east and the sun shone brightly, and syringing was practised daily. Once more, as soon as the flower-buds appeared, a pinch of guano was put in the water-can as before. In the month of April the house was as rich in leaves and flowers as any rose garden in July—richer, in fact, for roses properly forced are ten times more lovely in both leaf and bloom than the best that can be grown in the open air. The sorts included Teas, Perpetuals, and Bourbons; and I subjoin a picture of one of them, from a sketch made at the time they were at their best—several of them were sketched, in fact, because of their great beauty and the very simple manner in which they had been produced. If O P Q is

inclined to do this sort of thing, his first care should be to buy-in potted plants that have been kept in pits, and have never tasted heat, and as soon as they come home set to work to make up a bed to plunge them in. He may take his choice of plunging in the open air or under glass. If the most perfect beauty be desired, we must use glass for roses, for this rude elime smites their delicate cheeks too sharply, and it is only when sheltered that they become bright and fine in leaf and flower, without a stain or blemish.

S. H.

MY ORCHID HOUSE.—No. XII.

THE MILTONIA.

I do not intend, in the few words of praise that I shall bestow upon this truly magnificent genus, to assert that it should obtain a predominance over and above all the other orchidæ; but I think it ought to be more extensively cultivated, for it is worth the attention of the most fastidious. Upon questions of floral excellences, it certainly is by no means so easy to grow as some others, neither will it bear such rough-and-ready usage as some of the

commoner species and varieties of *Oncidiums*, *Stanhopeas*, and other orchidaceous plants that I could enumerate, were it either necessary or desirable to do so. What I mean by rough usage is, the species cannot be grown with the same degree of success in a low temperature, or in make-shift places—such as vineries or cucumber-houses, where they would have to submit more or less to the treatment required by the other occupants of the house—as they can in a house and temperature expressly devoted to the culture of these and other orchids. I should not recommend their culture being attempted without the advantages of a proper orchid-house, as it would in all probability only lead to disappointment. I do not say that the *Miltonia* cannot be grown anywhere but in an orchid-house, for I have grown some of the species in the pine-house, for that bears a very close approximation; but it is uphill work, and much best to confine the collection to hardier kinds; but when there are suitable places for growing them in, the extreme richness and beauty of the flowers are more than sufficient to repay every item of care that could be bestowed upon them. They have a remarkably dwarf and compact habit, and the flowers are thrown just sufficiently high above the foliage to show them off to the best advantage; and they are not flimsy with a washy appearance, like a common out-door annual—like some species grown in the orchid-house—and, moreover, are thought very grand, and considered of vast importance in the world comprised under the heading of these papers. To a novice I should say (and I care not who questions the soundness of the advice), get a good stock of *Miltonias*, bestow a little pains upon them, so that they receive suitable treatment, and there will be no disappointment in the amount of beauty they will furnish, and at the same time afford a pretty clear indication as to what stage of refinement as regards these matters the proprietor's mind has arrived at. The species comprising this genus grow capably in shallow baskets, for they do not require a great depth for the roots; but they are not suitable for suspending from the roof—they grow too close and compact for that purpose. The flowers could not be so readily seen as it is desirable they should be; they could, of course, be taken down from the roof, and put on the stage during the time the plants are in bloom. If grown in the ordinary flower-pot, which is as good a way as any, the pots should be filled to within a few inches of the level of the rim with large pieces of crock and a layer of small ones on the top, and the plant must be kept several inches above the level, say from three inches upwards, proportionate to the size of the pot and plant. I cannot too strongly urge the importance and necessity which exist for the base of the bulbs to be well elevated above the rim of the pot, to prevent the possibility of the least amount of stagnant moisture accumulating about them. A neglect of this precaution in potting the *Miltonia* is likely to result in a loss of a great part of the plants. I have tried several things for growing this genus in, and I find sphagnum suits it best. It favours the free development of the roots, which are rather fine and unable to penetrate a closer material so readily as the thick fleshy roots of some genera. In potting, the sphagnum should be pressed firmly about the roots, and as the plants have a very strong tendency to push out all the young growths in the same direction, this must be counterbalanced in each shift, or the plant will in a very few years get to one side of the pot, instead of the centre of the plant being in the middle. The only thing necessary is to bring the old part of the plant to the side, and thus keep the growing portion in the centre. As regards watering, great carefulness is required. Very little will satisfy its want through the winter; enough to keep the bulbs from shrivelling is all that is necessary, and sufficient only to keep the mass in a nice healthy condition, even when in full growth, will be enough. It should never through the summer get thoroughly dry or saturated; either extreme is decidedly injurious to the welfare of the plants. Syringing overhead should be avoided as much as possible, at all times. It is impossible to prevent a little water going over them when syringing the other plants, and it is not desirable to consider any one particular genus that requires rather peculiar treatment to the exclusion of all the others. The *Miltonias*, like the majority of orchidaceous plants, are propagated by division. The best time to do this is in the spring, immediately the young growth begins to push, but before they get too far advanced. A mean temperature of 65° through the resting season, and 75° to 85° through the like period of growth, will suit them. I think I have now said all that is necessary upon the culture of this beautiful genus, and at the same time I feel assured that the undermentioned species and varieties will, if they receive the treatment I have advised, thoroughly satisfy the cultivator that the amount of praise I have now meted out to it is by no means too much or undeserved.

M. candida is a splendid kind; the sepals and petals are yellow brown, with a pure white lip finely marked with pink. *M. Clowesii* is another fine species. *M. Morelli atrovirens* is a grand thing; sepals and petals purple, with a fine dark lip. *M. spectabilis* is a very good species; the sepals and petals are beautiful cream colour, with a large purple lip. There are also a few very good varieties of

Spectabilis that would be an acquisition to an extensive collection, but the four I have named would be enough for a small one.

GEORGE GORDON.

BEAUTY OF FORM IN THE FLOWER GARDEN.

Some of the best flower gardens in existence are annually embellished by plants of graceful and ornamental leafage, of which not one was to be seen in like positions half a dozen years ago. Of course everybody remembers when a flat-series of beds, with nothing more graceful or elegant in them than a mass of geraniums or verbenas, was considered the climax of successful flower-gardening; indeed, it is impossible to forget it, because that is the style that yet prevails in thousands of places to which a trace of this commendable taste for arranging verdant and graceful forms of leafage among the low-lying and brilliant flowers has not yet penetrated. The system of using plants distinguished by beauty of form (a higher beauty than that of colour, by the way) was first developed in continental gardens, and was much in vogue in Paris before we knew anything about it here. We were so much attached to loud colours, that nobody thought of introducing the system till Mr. Gibson first took it in hand at Battersea Park, and with a result with which most of our readers are probably familiar. And those who have not seen this display at Battersea cannot do better than pay it a visit some time during the coming summer or autumn, and they will probably confess that of all the garden scenes they have ever witnessed it is the most beautiful.

We may briefly describe it as a flower garden laid out in the irregular or gardenesque style, well sheltered and surrounded by a rising grove of trees, with many snug and receding bays here and there, where shade-loving subjects may find their wants supplied, and here and there sweeps of grass, dotted over with beds of the most diversified character, both as to shape and planting. There is an abundance of brilliant flowers of all kinds to be seen; but these are everywhere "set off" by a profusion of green and noble leafage: the eye, after being gladdened with colour, is soothed with the elegant verdure of arching Palm-leaves, and dwells with satisfaction on tropical foliage of all kinds, from large metallic-leaved *Caladiums* to tall *Castor-oils* and *Ferdinandias*, which have leaves of enormous size, and, growing to a considerable height, carry the eye up to the surrounding and intermingled trees. From the whole an impression is obtained which we might look for in vain from any flower garden of the ordinary type in which naught is to be seen but a spread of colour, as a rule, displayed in a tawdry and glaring way.

It needs but little consideration to discover the cause of the success of this mode of planting a flower garden. It is an approximation to nature's own plan of arranging vegetable beauty, whereas the ordinary one is in violent opposition to it. Among plants in a wild or untrammelled state the beauty of their colour is usually set in abundant green, and, even in the case of mountain and meadow plants of one kind that produce a wide blaze of purple or golden colour at one season, there is intermingled a spray of pointed grass and other leaves which tone down the mass, and quite separate it from the rude style of gardening that we deprecate.

But if we come to examine the most charming examples of our own indigenous or any other wild vegetation, we find that they are founded on flower and fern, trailer, shrub, and tree, sheltering, supporting, relieving, and beautifying each other, so that the whole array has an indefinite tone, and the mind is satisfied and delighted with the refreshing mystery of the arrangement. We may be attracted by the wide spread of purple on a heath or mountain, but if we go near and examine it in detail, we find that its most exquisite effect is by the side of a brook, where the long moss cushions itself beside it and the *Polypody* fronds peer forth from around the mass of heather. Everywhere we see nature judicious in the arrangement of her highest effects, setting them in clouds of verdant leafage, so that the eye is never palled, and monotony never produced—a state of things that it is highly desirable to attain as far as possible in the garden. It would not be wise to attempt its attainment by a literal copying of wild nature: that would not be creditable to the horticultural designer, and far from convenient. But the artist, while avoiding all literal rendering as base and useless in his compositions (which would not be compositions at all were they mere literal imitations), is still more careful not to outrage nature, and that too should be our plan. We may enjoy all the grace and verdure of the grove without making our gardens any the less manageable or convenient; but we may not with impunity, or with any hope of giving pleasure to the tasteful or educated eye, extract, so to speak, all the colour from our flowers and lay it down in unmitigated daubs. Such a course is too well calculated to give us all our pleasure at once, and make the garden as monotonous and unchangeable during its best season as the house-carpet; for, depend upon it, the first flush of flower on those beds is the highest beauty we shall see from them, and, no matter how long the months they continue in the selfsame state, there is none of the true and refreshing interest of the garden to be had from them. How are we to enjoy it then? By the culture of a tenfold greater number of plants in the first place (at present many flower gardens present but very few kinds), and by a tasteful arrangement and combination of the finer flowering plants with those of graceful habit, fine leafage, interesting associations, or distinct beauty, and by so arranging the garden and its plants that there may be a continuity of beauty and interest from the dawn of spring till the close of autumn. But in this essay we have only to deal with a portion of what is called the summer garden, and we will therefore glance through our catalogue and see what plants of fine foliage, graceful or peculiar leafage, may be used for the flower garden with good effect, taking hardy, tender, annual, biennial, or perennial plants as they come, and indicating the best way of raising each kind from seed.—*Carter's Vade Mecum*, 1867, Part I.

A CHEAP BAROMETER.—A countryman in the neighbourhood of York has discovered a natural barometer, being no other than a spider's web. When it is about to rain and he windy, the spider shortens considerably the last thread to which his web is suspended, and leaves it in this state while the weather remains variable. If the insect lengthens its thread, it will be fine, and the fineness may be guessed by the length they attain to. If the spider remains inactive, it is a sign of rain; if, on the contrary, it begins to work while it rains, it betokens a speedy change for the better. The spider alters his web every twenty-four hours, and if these alterations are made a little before sunset the night will be fine.

What is the difference between a tunnel and a speaking trumpet?—Why, the one is hollowed out, and the other is hollowed in.

Calendar.

WORK FOR WEEK COMMENCING MARCH 30.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—There cannot be too much vigilance now in keeping down weeds, hoeing between crops, earthing up peas and beans, and promoting growth by any other means that suggest themselves, such as top-dressings of soot and guano, &c. Our climate affords us but a short season, and it is our duty to make the very most of it.

BROCCOLIS to be sown in variety and quantity for use in autumn, winter, and next spring. Sow *Walcheren*, *Snow's Winter*, *Knight's Protecting*, *Dilcock's Bride*, and *Wilcove Late*. Others if needful, but these are first-rate.

CAULIFLOWERS may be planted out in southern and western districts, but in cold or damp places it is as yet too early, as if cold weather occurs many will be destroyed, and the rest will be crippled. Plants pretty strong in seed-pans will be greatly benefited by planting them out in frames on a slight heat, or they will do without it if in light rich soil, and carefully managed as to giving air, &c.

CELERY standing out will now begin to bolt, so to save some as late as possible, take up the remainder of the crop, and lay it in by the heels in a shady corner, or pack it in dry sand in a shed till wanted. Plants in seed-pans in a forward state to be pricked out on a bed over fermenting material giving a gentle heat; the surface soil to be light and rich. In the absence of any source of heat, make a bed of dung and leaf-mould on a hard foundation; put a frame over, and prick out the plants in it.

LETTUCE to be pricked out from seed-pans as advised for celery and cauliflower. The winter bed may now be thinned out, putting the plants on well-manured ground, but leaving some in the bed to supply a few small hearts earlier than those planted out will do.

ONIONS.—Sow main crop.

PEAS.—Sow succession crops, and earth up and stake any that are ready.

BEANS to be earthed up; successions to be sown. Sow none but *Windsor* now, if quality is of any consequence.

Flower Garden.

CHRYSANTHEMUMS struck from cuttings now will make fine plants, and growers are advised to prepare at once for raising the whole of the stock required for bedding and other purposes.

CLEAR UP everywhere and everything that has a touch of untidiness about it. At the first break of genuine sunshine the ladies will be exploring the garden, and there ought not to be a withered leaf, or a broken flower-pot, or a scrap of stick, or cast-off tally anywhere visible. Make all bright and firm with broom and roller, and thin out dead wood from all trees and shrubs. This is a time to edge off lawns, and give beds and borders a final pointing over.

EVERGREENS.—This is a capital time to move them, and to plant beds, borders, and edges. If the weather is dry, water freely, or, better still, mulch heavily; after planting, give no water at the root, but syringe overhead two or three times a day while they are making new growth.

AURICULAS to have abundance of air; shade during strong sunshine; water enough to promote healthy growth and free bloom.

BEDDING PLANTS to be shifted if needful, but generally speaking the business of importance now is to get them hardened off by transference to pits, cradles, &c. Some who have to deal with large quantities, put them into trenches dug as for celery, and lay boards, old lights, or mats over at night.

IVY on walls and fences should now be stripped of its leaves and loose shoots; any gaps to be filled up if possible by nailing in, and the whole to be left as a close feltwork of bare stems. It is a good time to put in cuttings.

CHRYSANTHEMUMS are growing freely, and must be shifted on and stopped as required without any delay beyond the proper time. It is the securing an *early* growth that is the key to success in forming fine specimens and obtaining an abundance of bloom.

ROSES to be pruned if not yet done; no danger now in any part of Britain, and trees may be pruned with the rest; the young shoots are the most valuable, and these must be left a sufficient distance apart to allow light and air to benefit them equally.

CARNATIONS AND PICOTEES FROM SEED.—The best mode of raising seedlings is by sowing the seed in pans in April in good sandy soil. Let it be sown half an inch deep. No heat should be used, as it is the cause of their damping off. Too much moisture must not be given, and shading from the midday sun must be afforded. Keep clear from weeds, slugs, and green-fly. The latter are easily destroyed by dusting strong snuff over the plants. They may be planted out about the first week in August, in rows about ten inches apart, in good soil. Water them carefully until they have become established.

IVY BORDER.—To make a nice ivy border is a very easy affair, and this is the best time of year to do it. The ground should be dug and well broken, and some manure added. The breadth of ground broken and manured for the purpose should be at least a foot wide, better if eighteen inches. Procure a supply of pot plants of Irish ivy three to five feet high. These may be obtained from almost any nursery at from one to two shillings per plant. Cut them all to three feet in length, and plant them three feet apart. When planted, train them all one way, and peg them down, placing the branches six inches apart; they must be planted firm, and have plenty of water when the weather is dry all through the first season, after which they will never want watering. When they begin to grow, have all the old leaves cut off, but without damage to the young shoots. Let them grow as they like all the season, but assiduously peg the new shoots so as to cover the ground regularly. The after management is a matter of clipping and pegging to taste. Common English ivy makes nice edging, but is not so quick or luxurious as the Irish. Where expense is no object, we should prefer for a green ivy edging *Hedera helix taurica*, a beautiful small-leaved ivy; and for a silvery edging *Hedera helix argentea*, the most showy and free-growing of the variegated kinds. But for all ordinary purposes the Irish ivy is the best, and a well-made edging of it is beautiful after having been planted three years. In districts where manure is not easily obtainable, it may be dispensed with, for the fact is ivy will grow in any soil; moreover, if variegated ivies are planted manure is not wanted, as it might weaken the variegation. Nevertheless, for a fine rich growth of any of the green-leaved kinds, deep digging and manuring are the *proper* steps to take.

Fruit Garden and Orchard House.

FRUITS IN SEASON DURING APRIL.—*Apples*: Alfriston, K; Ashmead's Kernel, D; Boston Russet, D; Brabant Bellefleur, K D; Brownlee's Russet, K D; White Calville, K; Cockle Pippin, D; Coe's Golden Drop, D; Cornish Gillyflower, D; Court Penduplat, D; Dutch Mignonne, K D; Forman's Crew, D; Golden Harvey, D; Gooseberry Pippin, K; Hambleton deux Ans, K D; Holbert's Victoria, D; Hubbard's Pearmain, D; Lamb Abbey Pearmain, D; Lemon Pippin, K; Minier's Dumpling, K; Newtown Pippin, D; Nonpareil, D; Norfolk Beefing, K; Northern Greening, K; Northern Spy, K D; Ord's, D; Pile's Russet, D; Pinner Seedling, D; Reinette du Canada, K D; Reinette Grise, D; Reinette Van Mons, D; Ribston Pippin, D; Ross Nonpareil, D; Royal Russet, K; Screveton Golden Pippin, D; Spring Ribston, D; Striped Beefing, K; Sturmer Pippin, D; Sweeny Nonpareil, K; Tulip, D; Wheeler's Russet, D; Winter Pearmain, D; Winter Quoining, K D; Wyken Pippin, D.

Pears.—Angélique de Bordeaux, D'Avril, Bellissime d'Hiver, Bergamotte d'Espere, Bergamotte d'Holland, Beurré Bretonneau, Beurré de Rance, Bezi de Bretagne, Bezi Goubault, Cassante de Mars, Easter Bergamot, Josephine de Malines, Morel, Prevost, Uvedale's St. Germain, K; Van de Weyer Bates, Zephirin Louis Gregoire, Inconnue, Easter Beurré, Ne plus Meuris, Commissaire Delmotte, Aglaé Gregoire, Colmar Delabaut, Prince Albert, Madame Millet, Doyenné d'Alençon, Bezi Mai.

Grapes.—Of last year's crop there may still be good bunches of Lady Downe's Seedling, Kempsey Alicante, Trebbiano, and Trentham Black. The earlyinery may now supply one or all of the following: Chasselas Musqué,* Muscat Hamburg,* Purple Constantia, Red Frontignan, White Frontignan,* Black Champion, Black Hamburg,* Black Prince, Trentbam Black, Early Black Bordeaux,* Grove End Sweetwater, Early Chasselas, Muscat Lierval,* Early Auvergne Frontignan, Early Smyrna Frontignan,* Golden Hamburg, Royal Muscadine,* White Sweetwater. As this is a good time for planting vines (the very best months are March and June), we have attached an asterisk to a few that are particularly well adapted for early forcing.

Straubberries.—The first batch of forced plants may supply ripe samples of Black Prince, Keen's Seedling, British Queen (seldom good before May), Prolific Hautbois, Prince of Wales, Sir Harry, Victoria, Cutkill's Princess Royal.

Peaches from the forcing-house may now be looked for; the first supplies will probably be any or all of the following: Red Nutmeg, Small Mignonne, Early Grosse Mignonne, Early York, Abec.

Nectarines.—Fairchild's (second-rate, but early), Elruge, Rivers's White, Bowden.

Gooseberries.—The following may, in early districts, supply green berries for culinary purposes: Early Sulpbur, Early White, Keen's Seedling, Miss Bold, Wilmot's Early.

Figs.—Though it is early yet for supplies of ripe figs, the following varieties may furnish the table towards the end of the month: Angelique, Black Provence, Early Violet, Marseilles, White Ischia.

GRAFTING to be proceeded with, and any lately done to be looked up; as if the clay cracks, and is neglected, the grafts will probably fail as soon as they begin to start.

Greenhouse and Conservatory.

GREENHOUSE.—A general clearance may now be made of all such plants as can be removed to turf pits, frames, and other cool receptacles. This will make more room for spring flowers, and give a better chance to Pelargoniums and other specimen plants now growing into shape and size. The best shading for plants in flower is tiffany hung inside in large bag-like festoons. Hitherto shading has not been wanted, but it will be henceforth, and should be got up while the house is in process of re-arrangement.

CAMELIAS require careful attention now. As soon as the new growth begins there is an end of bloom, and any unopened buds that may remain may as well be removed. The temperature for growing plants is 65° by day and 55° by night; the atmosphere moist, and the position shady. But there must be no coddling; give air at all favourable opportunities, or the new growth will be long and weak, and the next season's bloom of necessity inferior.

HEATHS AND NEW HOLLAND PLANTS.—Repot as required, using fibry peat and plenty of drainage. Newly-potted plants to be carefully watered until they begin to make new growth, which is always a sign they have taken hold of the new soil.

CACTI and succulents generally require attention now if they have not yet been dressed up for spring. It is a mistake to suppose that, like the chameleon, they can live on air, or like some fishes on water only. The fact is they want liberal feeding, and as long as sunshine is abundant ought to be grown freely, and then be rested perfectly, and the result will be they will bloom abundantly. Those that are pot-bound may have a small shift; some of the old soil to be picked out from the roots; the potting to be done with care, plenty of drainage, the soil equal parts broken brick and chalk of the size of walnuts, good turfy loam, and rotten cow-dung. Those not in need of a shift should have a little of the old soil removed and replaced with mixture; give plenty of water while they are growing in earnest, and as much light as possible.

BALSAMS to be kept growing freely; if starved they are spoiled. Let the soil be sweet, light, and rich, with plenty of fibre and thoroughly decayed manure. Keep the plants near the glass, and let them have plenty of water.

DAHLIAS may now be struck in quantities with the greatest ease, and they will root quickly. It is a good plan to put the cuttings into pots in which there is a small empty pot inverted, then fill up with light stuff, and put an inch of sand on the top. From this they may be removed with nice bundles of roots.

HERBACEOUS CALCEOLARIAS will be smothered with green-fly now that the weather is mild, unless they are well looked after. The best preventive is to keep them growing freely; and if any need to fumigate, do it promptly and effectually. Tobacco tissue answers admirably for soft plants of all kinds, as it delivers a killing cloud of pure tobacco smoke, and there is no danger of the nitrous gas, which tobacco paper so often contains too much of, and the operator need not make himself sick, as all he has to do is to set the stuff going with a few hot cinders, and then shut up the house and go away.

FUCHSIAS are growing freely, and must be shifted as they need it. Over-potting, usually to be avoided, is not an evil with Fuchsias, if they are warm and are not soddened at the root. A moist atmosphere is needed

to make good specimens. Put in a few more outtings to make small plants for late bloom, and pot off any newly-rooted cuttings as soon as possible.

PLANTS IN FLOWER IN APRIL.—*Cinerarias*, *Cytisus*, *Primulas*, and *Azaleas* are now in their full splendour, in houses that have only fire enough to keep the frost out. In mixed collections of first-class character, we expect during the month to see some of the following in bloom: *Chorozema augustifolia*, *Hagelii*, *Henschmannii macrophylla*; *Acaëus conferta*, *Dillwyniifolia*, *rotundifolia*, and several others; *Abutilon striatum*, *Anthocercis viscosa*, *Berkheya obovata*, *Cantua bicolor*, *Aotus inoana*, *Cytisus nubigenus laniger*; *Actinotus helianthi*, *Athanasia tomentosa*, *Kohium patrum*, *giganteum*; *Hindia alba*, *violacea*; *Daviesia angulata*, *polyphylla*, *genistoides*; *Datura Waymannii*, *Echoveria secunda*.—*Frame*: *Narcissus bulbocodium*, *nanum*, *poeticus*; *Dielysia spectabilis*, *Russian* and *Neapolitan violets*, *Scilla siberica*, *Ornithogalum umbellatum*, *Arabium*, *pyramidalis*, *Leucojum vernalum*.—*Ericas*: *dilecta*, *Banksiana*, *Cliffordiana*, *arborosa*, *echiniflora*, *fuscularis*, *metuliflora*, *nivea*, *persolata*, *perspicua nana*, *costata*, *racemosa*, *Smithiana*, *triflora*, *campanulata*, *trossula*, *nivea*, *Cistifolia*, *daphnoides*, *sulphurea*, *moschata*, *hybrida*, *mirabilis*, *obovata*, *Patersoniana*, *quadriflora*, *expansa*, *princeps carnea*.

ORCHIDS IN BLOOM IN APRIL.—*Saccolabium miniatum*, *Vanda insignis*, *V. suavis*, *Arpophyllum giganteum*, *Burlingtonia fragrans*, *Leptotes serrulata*, *Cattleya Skinneri*, *Phalenopsis Schillioriana*, *Ærides Fieldingi*, *Dendrobium aduncum*, *D. anosum*, *D. chrysanthemum*, *D. clavatum*, *D. eripidatum*, *D. Dalhousianum*, *D. densiflorum album*, *D. fimbriatum*, *D. fimbriatum oculatum*, *D. lituiflorum*, *D. Pierardii latifolium*, *D. primum*, *D. triadenium*, *D. Wallibianum*, *Epidendrum bicornutum*, *E. macrochilum*, *E. macrochilum roseum*, *Odontoglossum Poscatorei*, *Oncidium ampliatum majus*, *O. sarcoodes*, *O. sessile*.

SOLANUM CAPSICASTRUM.—The cultivation of the scarlet-berried *Solanum* is so exceedingly simple that any one with ordinary appliances and ordinary skill may have a grand display of them in the autumn in the conservatory. There are several species and varieties which produce red berries; the one commonly grown hitherto has been *S. capsicastrum*; but far better, because it makes a bolder bush and bears larger berries, is *S. pseudocapsicastrum*. To get up a stock of this proceed as follows: Place an old plant in a warm house, and frequently syringe it. When the young shoots are two inches in length, take them off and dip them into sand in a heat of 60 to 70 degrees. When rooted, pot them in light sandy compost, and give them a moderate heat until they begin to grow; or sow the seeds in light soil, and place in a steady heat. The present is the proper time to begin with either seeds or cuttings. From that time gradually inure them to ordinary greenhouse temperature and to fresh air, so as by degrees to get them quite hardy by the middle of May. Then plant them out in a piece of rich light soil, in the full sun, fifteen inches apart; give plenty of water all the summer, and slightly train them out, so as to form open heads. They will require to be twice stopped by nipping off the points of all the shoots in June, and after that must grow as they please. About the middle of September take them up very carefully and pot them. In this process the roots must be preserved from injury, and as much earth kept about them as possible. When potted, stake them out neatly; shade for a week, and after that keep them in the sunniest part of the greenhouse. If you follow this prescription, their appearance in November ought to be that of neat shrubs, two feet high and eighteen inches through, completely smothered with bright scarlet berries, full double the size of holly-berries.

Stove and Orchid House.

STOVE PLANTS should have free ventilation early in the day, when the weather is bright, with westerly winds, which will allow of shutting up early, to reduce the firing. Plants that have flowered, and are not yet cut down, must have immediate attention, for the tendency of everything now is to grow, and the growth from the first should be as we wish it; far better than allowing growth at the tops of shoots that are to be cut off, for that compels the plant to make a second start from buds lower down, which is debilitating. Plants cut down need a bottom-heat of 75° to 80° to start them into growth, and when growth has commenced they must be shaken out and re-potted.

ACHIMENES started into growth may now be put into pans for flowering, and have a little bottom-heat to give them an impetus to extend their roots.

ORCHIDS demand an increase of heat, with more syringe, and the atmosphere some degrees more moist. Beware, however, of overdoing the watering where succulent spikes are rising, and, as far as possible, do not allow water to lodge in the hearts of the plants. All kinds of vermin are now active, and must be trapped, or the mischief they will do to the new growths will be disastrous. Shade from the midday sun.

Forcing &c.

CUCUMBERS will be greatly benefited by judicious ventilation in the morning when the sun shines. Stop the principal shoots as soon as they reach the sides of the frames, and then stop all laterals one joint beyond the fruit; and where two fruit show nip one away. Be careful not to break the leaves in any of these operations. An occasional thorough soaking of the bed is desirable, but it must be done when the weather is bright and warm.

CHERRIES require more water and air after the fruit is stoned, which may be known by their commencing to swell again.

MELONS advancing to a fruiting state to have a good temperature by linings or otherwise, and though they require less water and more light than cucumbers they must not be too dry, or the red-spider will get possession. Young plants lately turned out must be kept rather close, to encourage free rooting, but as soon as growing freely to have air, or they will get drawn. In thinning the shoots, endeavour to promote a regular growth, evenly spread out and rather thin, so that every leaf will be fully exposed to the light. The night temperature to be 60°, rising by day to 75° or 80° at the utmost; if beyond 75°, give air to reduce the heat. This is a good time to sow for succession, and also for those who must depend chiefly on sun-heat for their produce.

PEACHES that have got through the stoning process to have more water at the root, and occasional syringing to keep down red-spider and help the young growth. Those lately set to be thinned moderately, remembering that in the process of stoning a considerable quantity of fruit will fall.

PINES swelling their fruit will be benefited by clear soot-water; when ripening to be kept rather dry. The fruiting-house to range from 65° to 80°, the utmost day temperature to be 85°, and that only when there is a strong sun-heat. Succession stock may go down to 60° at night, and

rise to 80° by day. Plants newly potted to be watered with great care until they begin to make new roots, but dew them frequently to keep them fresh.

STRAWBERRIES must have as much light as possible in every stage of forcing, and never suffer through insufficiency of water. A good heat may now be allowed. Where the berries are acquiring colour, give less water at the root, and none overhead.

VINES in the first house may be supposed to show fine bunches changing colour. The temperature may be raised, and this will allow of freer ventilation; neglect now will cause the fruit to be badly coloured. Vines just showing fruit to have the bunches thinned as soon as possible, and with the greatest care. Tie up the shoulders carefully, and avoid all rough usage of the bunches, and do not allow the hand to touch the berries, as rust is commonly the result of such contact. Ply the scissors so as to leave plenty of room for berries to swell, and to give the bunches as fine an outline as possible. Remove useless shoots; stop laterals; see that the border is moist enough a foot below the surface.

THE POTATO DIGGER'S SONG.

(From "Poems by T. C. Irwin.")

Come, Connal, aculella, turn the clay,
And show the lumper the light, gossoon,
For we must toil this autumn day,
With Heaven's help, till rise of the moon.
Our corn is stacked, our hay secure,
Think God! and nothing, my boy, remains
But to pile the potatoes safe on the fure
Before the coming November rains.
The peasant's mine is his harvest still;
So now, my lad, let's dig with a will—
Work hand and foot,
Work spade and hand,
Through the crumb'y mould:
The blessed fruit
That grows at the root
Is the real gold
Of Ireland.

Och! I wish that Maurice and Mary dear
Were singing beside us this soft day!
Of course they're far better off than here;
But whether they're happier, who can say?
I've heard when it's morn with us it's night
With them on the far Australian shore;
Well, Heaven be about them wid visions bright,
And send them childer and money galore.
With us there's many a mouth to fill,
And eo, my boy, let's dig with a will:
Work hand and foot,
Work spade and hand,
Through the brown dry mould;
The blessed fruit
That grows at the root
Is the real gold
Of Ireland.

Ah, then, Paddy O'Reardan, you thundering Turk,
Is it coarting you are in the blessed noon?
Come over here, Katty, and mind your work,
Or I'll see if your mother can't change your tune.
Well—youth will be youth, as you know, Mick,
Sixteen and twenty for each were meant—
But, Pat, in the name of the fairies, avic,
Defer your propoals till after Lent;
And as love in this island lives mostly still
On potatoes—dig, boy, dig with a will:
Work hand and foot,
Work spade and hand,
Through the harvest mould;
The blessed fruit
That grows at the root
Is the real gold
Of Ireland.

Down the bridle-road the neighbours ride,
Through the light ash shade, by the wheaten sheaves;
And the children sing on the mountain side,
In the sweet blue smoke of the burning leaves.
As the great sun sets in glory furled,
Faith, it's grand to think, as I watch his face,
If he never sets on the English world,
He never, lad, sets on the Irish race.
In the west, in the south, New Ireland still
Grow up in his light. Come, work with a will—
Work hand and foot,
Work spade and hand,
Through the native mould;
The blessed fruit
That grows at the root
Is the real gold
Of Ireland.

But look!—the round moon, yellow as corn,
Comes up from the sea in the deep blue calm:
It scarcely seems a day since morn;
Well—the heel of the evening to you, ma'am.
God bless the moon; for many a night,
As I restless lay on a troubled bed,
When rent was due, her quieting light
Has flattered with dreams my poor old head.
But see—the baskets remain to fill!
Come, girls, be alive—boys, dig with a will:
Work hand and foot,
Work spade and hand,
Through the moonlit mould;
The blessed fruit
That grows at the root
Is the real gold
Of Ireland!

THE STRUGGLE FOR EXISTENCE.—One of the greatest pests of New Zealand (on the cultivated lands) is the common English Sheep-sorrel (*Rumex acetosella*), called by the natives the red sorrel, and said by them to be a native of Tasmania. This plant spreads with singular rapidity, its roots forming a perfect mat, and the smallest fragment throwing up a stem. Where it is present in the ground, scarcely any of the ordinary crops can be obtained. All the usual processes of cultivation, such as fallows, &c., utterly fail even to mitigate the evil, and farmers were in despair until it was found that in the "struggle for existence" even this weed could not make head against the greater vigour of the white clover. I have seen hundreds of acres of broken-up land so completely overgrown with this plant as to appear like a uniform red patch in the landscape, but upon which, at the end of two years, after it had been "laid down" with white clover and Italian rye-grass (which by itself would have done no good), scarcely a specimen of the sorrel could be found.—Travers, in *Natural History Review*.

Correspondence.

SHADING.—My lean-to greenhouse, 30 by 12 feet, used for a mixed collection of plants and four vines, is covered with 21 oz. glass, 20 by 15 inches, and shading for summer is a serious matter. I was advised to dissolve a piece of lime as big as a hen's-egg in a little hot water as possible; then take a quart of skimmed milk and put in the slaked lime, stirring well; and whitewash the glass inside "or outside," on a dry day about the middle or end of April. If put on the outside, the autumn rains will wash all clear for winter. This I tried last year; it answered very well inside, but at times the house would get hotter than I wanted. In September, a clean brush and water made the glass all right for winter work. Can you, Mr. Editor, or any of your readers, tell me of a better or cheaper shading? Mine cost me one penny for milk, and about two hours labour whitewashing.

POLLY.

Replies to Queries.

B. Pratt.—The frosted potatoes, apples, and other refuse, had best be put at the bottom of a trench in the kitchen garden.

Renovating Old Lawn.—H. W.—In sowing grass-seeds to mend an old lawn, the best mode of procedure is to have the bare places dug over and enriched with good rotten manure, and all the stones and lumps raked off preparatory to sowing. Then sprinkle the seed pretty thick, and cover with fine earth. It is a good plan, when the job is only a small one, to sift the earth over the seed; but when there is a large space to be operated on, the workmen have a few good heaps of fine soil and throw it with the spade. In a majority of cases old lawns may be revived by simply sprinkling with nitrate of soda two or three times in the season. If a growth of clover is desired, it may be obtained generally by giving a good surface-dressing with superphosphate of lime.

Seedling Hollyhocks and Picotees.—H. W.—Plant them out as soon as the weather is mild and open—the sooner the better after March is out.

Nitrate of Soda and Superphosphate for Lawns.—S. R.—We have not recommended solution of nitrate of soda for grass-lawns, but the dry salt spread upon the surface, leaving it for the rains to wash it in. The best proportion in which to apply it is at the rate of 4 lbs. to one square rod; or if another method of proportioning will better suit persons unaccustomed to land measure, say 4 lbs. to every thirty square rods. This is at the rate of about 6 cwt. to the acre. Now the usual rule of applying such a manure as saltpetre is at the rate of 2½ cwt. to 3 cwt. per acre, so that we feel bound to say we have used saltpetre at the rate of 4 lbs. per square rod with the most satisfactory results. Lawns that were flinty, patchy, and sour, became soft and springy with the abundance of fibre produced, and the sward acquired a beautiful freshness and closeness of growth. Until we had used this large quantity, and patiently waited for the result, we advised the use of only 1 lb. per square rod; and that we can say is enough to work wonders, but the dose should be repeated at least twice—say three dressings in all, in April, May, and June. On some lawns there is plenty of grass and no clover, and during very hot dry weather such lawns become burnt and unsightly, whereas clover does not quickly burn. To promote the growth of clover, any of the salts of lime may be used. Even siftings of lime core from the builders' will be good as a top-dressing, but a quicker result may be obtained by the use of superphosphate of lime in the same proportions as we recommend the use of nitrate of soda, that is, from 1 lb. to 4 lbs. per square rod, according to the state of things to be remedied.

Geraniums attacked by Grubs.—Subscriber.—It is certainly not usual for geraniums to be attacked, as yours have been, by a grub eating its way from the base of the stems upwards. Yet there is nothing novel in the event, for the most experienced cultivators are sometimes caught in this way. You have probably used some newish turf or other material in the compost in which the eggs were concealed, and your chief matter is how to get rid of them. The surest way to proceed would be to knock them all out and repot them. Preparatory to doing so, as probably all your compost is foul with the eggs or grubs, it would be prudent to prepare sufficient for the repotting, and subject it to strong heat in an oven, or by any other method most convenient. Or if you could saturate the whole with boiling water, and then spread it out on a flue, or wherever it would dry quickly, you could repot and be rid of your plague, and by a little nursing the stock would soon recover. There is a yet more simple method of dealing with plagues of this sort, which we ourselves were driven to last year to save our pot-plants of *Raphanus caudatus*; and that was to plunge them to an inch or two below the rim of the pot for several hours, by which the grubs were drowned and floated out, and the plants were none the worse for the operation. We do not recommend this course with geraniums, but it might be safely done with tepid water on a fine day, and a little common salt in the water—say at the rate of one pound to four gallons—might increase its efficacy without hurting the plants.

Altering Greenhouse, &c.—J. L.—Without a sketch we cannot understand your case. You do not say where the boiler is. If at west end of greenhouse, you can easily enough heat the propagating house alone or in conjunction with the greenhouse. Without a sketch we cannot advise with any satisfaction, but it matters not how rough the sketch is.

Mistletoe.—Ernest.—The simplest and surest way to obtain a growth of mistletoe is to squeeze the seed and pulp out of the skin of the berries, and apply it to the bark of apple-trees in the month of March. This is the way in which nature spreads the plant. The mistletoe thrush cleans his beak on the bark, and here and there leaves a seed glued on. The customary method with gardeners is to make an incision in the bark and introduce the seed, but this is a customary failure; hence much talk about how to grow mistletoe, but little mistletoe to be seen. Your letter was sent unpaid, and quite by accident was paid for, it being the rule in our office to refuse unpaid letters.

Potato Planting.—R. W., Boston.—You ought to have planted during the fine weather in the latter half of February. On your cold wet soil, it is no use to attempt to plant now. Wait for fine weather, and plant when the ground is dry enough to crumble. If potatoes are planted in mere dust, they may do well, but if stuck in paste, growth is out of the question.

Forced Vines.—W. Watson.—We do not pretend to say that giving "front air" is the cause of your grapes shanking, but the gardener who holds that opinion may be right, as he judges on the spot, and we know nothing of the shape or size of your house. If draughts of cold air blow over the bunches, their shanking may be expected, and "front air" may

be the cause of it. There is no doubt, however, that in your practice the mistake is an excess of atmospheric moisture. We fully believe you might benefit by giving less air and less water; do not for the present give air earlier than eight a.m., and shut up about two, with a temperature of at least 85°. As to the best practice in giving air, front or back, it matters not which way fresh air reaches the vines; but it does matter that it should not come as a cold blast, but should move over a warm surface on its way to the vines. Covering the border with boards to throw off snow and rain is certainly a commendable practice. The best hook on the vine is that by Mr. William Thomson of Dalkieth.

M. P. may hear of the things inquired for by applying to Mr. Cannell, Fuchsia Nursery, Woolwich.

Roses eaten.—M. P.—The holes in the stems of standard roses are probably caused by the grub of the wood-leopard moth. There is no cure for the mischief done; some of the roses so attacked will probably die. When dwarfs are attacked, the loss amounts only to the branch the grub bores; when that is cut down, it is soon replaced by another.

Pæonies and Pyrethrums.—G. B., Blackburn.—This is a good time to buy and plant, though the autumn is to be preferred. Your position, climate, &c., are all that these things require to do well; the fact is, they are first-rate flowers for the suburbs of towns. Since your ground is well drained, you may reasonably expect to grow pæonies, pyrethrums, dahlias, and hollyhocks well. For tulips it would be advisable to improve the staple by the admixture of rotten dung and sand. We cannot advise you whether to buy the cheapest or the dearest kinds of pyrethrums and pæonies; you are the best judge of your own purse; but the most expensive kinds are as hardy as the cheapest, and occasion no more trouble to grow them well.

J. H., Woolwich.—We have made inquiries for you, but without success to our own liking. Perhaps you had better advertise.

Vinegar and Water as an Insecticide.—Inquirer asks if any of our readers have tried vinegar and water as a means of preventing insects depositing their eggs on the leaves and bark of trees, &c. Some time ago we gave an extract from the minutes of the Society of Practical Horticulture of the Rhone on the subject, and have heard nothing since.

Fern-case, London Flowers.—Lilian.—It is against our rule to recommend dealers, but you may find amongst those that advertise in this work several who supply fern-cases. The following are good subjects for a London garden: *Chrysanthemums*, double white *Pyrethrum*, and the new florist's *Pyrethrums*, which Mr. Selter keeps in great variety; *Oenothera Fraseri*, *Iberis sempervirens*, *Alyssum saxatile*, common white *Lily* and *Martagon Lily*, *Solomon's Seal*, *Achillea millefolia* roses, *Achillea ptarmica*, *Spiraea filipendula*, herbaceous *Pæonies*, *Dielytra spectabilis*, *Everlasting Pea*, *Veronica spicata*, *Campanula carpatica*, *Campanula persicifolia*, *Campanula nobilis*, common *Spiderwort*, or *Tradescantia Virginia*, *Centranthus rubra*, *Hemerocallis flava*, *Helianthus angustifolius*, *Helianthus latiflorus*, *Lysimachia nummularia*, *Sedum acre*, *Sedum fabarum*, *Sempervivum montanum*. These are all good things, and will grow and flower well wherever they can get a bit of sunshine. They may all be obtained in pots or tufts from the open ground at a nursery where hardy plants in any great variety are kept. We can advise you of a few hundreds more, but perhaps these will suffice for the present. Any that you determine to have, procure and plant at once.

Ivy Leaves.—J. E.—No. 1 is *Hedera helix marginata argentea*; that is the old silver-margined. No. 2, *helix aurea maculata*, the gold-blotched English. No. 3 is *helix marginata elegantissima*, the most elegant margined English. No. 4 is *helix minor marmorata elegans*, the small elegant marbled leaved. No. 5 is Irish, or *Hedera canariensis*; the English is much smaller, less richly coloured, and more distinctly veined. No. 5 is an incomplete leaf, very much indeed like *Algeriensis*, the Algerian ivy, which is always a lighter colour than any other. Much obliged for the hint about the *Araucarias*.

CATALOGUES.

A. FORSYTH, STOKE NEWINGTON, LONDON, N.—*Catalogue of Chrysanthemums, Dahlias, Fuchsias, and Geraniums.*—This useful list is prefixed with a short paper on the Cultivation of the Chrysanthemum, of which it is well known Mr. Forsyth is a perfect master. Having but lately had Mr. Forsyth's practice before them in his own words, our readers will be prepared to find in this catalogue useful hints and advices; and they will not be disappointed.

GEORGE RAWLINGS, WATERLOO ROAD, ROMFORD, ESSEX.—*Catalogue of Dahlias for 1867.*—Being a large grower of this flower, and the raiser of a very large number of the best varieties in cultivation, purchasers may depend on Mr. Rawlings's descriptions and estimates of merit. Dahlias are cheap now to what they used to be. There are in this list only two varieties entered at anything like old-fashioned prices, namely, *Aurora*, a superbly formed flower, the colour delicate rose, and *John Sladden*, a large bold flower, nearly black, and the best dark dahlia out. These are offered at half-a-guinea each; as for the rest, they range from 3s. to 9s. per dozen; so lovers of dahlias need not go short of gratification.

AUGUSTE VAN GEERT, GHENT.—*Extract of General Catalogue of Plants.*—This contains a good selection from the general catalogue, and is prepared expressly for English customers. The subjects comprised are various, comprehending, in fact, every department of stove, greenhouse, and hardy plant growing.

JOHN SALTER, WILLIAM STREET, HAMMERSMITH, LONDON, W.—*Catalogue of Chrysanthemums, Dahlias, Pæonies, Pyrethrums, Geraniums, Variegated Plants, &c.*—This is always an interesting catalogue, and quite different from every other. In the list of novelties are all the chrysanthemums we reported on in the MAGAZINE of Dec. 1, last year, and some few others added. The lists of pyrethrums, pæonies, phloxes, and pentstemons are first-rate. The list of geraniums, though copious, omits a good many that ought to be there. The list of hardy variegated plants is the best of the kind extant.

AMBROISE VERSCHAFFELT, RUE DU CHAUME, GHENT.—*Price Current, No. 79, for Spring, 1867.*—A capital small catalogue, indicating the range of selection in the several classes of stove, greenhouse, and hardy plants. There is a long list of moulan pæonies.

SENT with a couple of ducks to a patient by the celebrated Dr. Jenner:—

"I've despatched, my dear noddam, this scrap of a letter,

To say that Miss Wilson is very much better;

A regular doctor no longer she lacks,

And therefore I've sent her a couple of quacks.

The Gardener's Magazine.

SATURDAY, APRIL 6, 1867.

TULIPS WITH VARIEGATED LEAVES have hitherto been scarce, but the Dutch cultivators are bestowing their attention on such eccentricities, and in the course of a few years we shall probably have at our command a quite long list of varieties so characterized. It will be seen by a report on new varieties of hyacinths and tulips, in another part of this sheet, that in inspecting a series of new varieties in the nursery of Mr. Burley of Bayswater lately, we met with several handsome varieties with well marked variegated leaves. These cannot fail to be useful when they can be placed in the hands of cultivators at moderate prices. They are, of course, at present rather costly; but tulips differ from some other bulbs in that, if we once obtain them, we never need lose them, and may, in fact, keep and increase them nearly as well as the most experienced of the Dutch growers. It happens that we are rather in want of tulips with variegated leaves, that is to say, to gratify a love which the abundance of variegated-leaved plants has created or awakened. At the time of year when early tulips are at their best, variegated-leaved plants are for the most part at their worst. It is in the summer and autumn, generally speaking, that we see variegated leaves in perfection; to few of them is it given to show their best colours in the months of January, February, and March; and to few also it is permitted that beautifully variegated leaves shall be succeeded by gorgeously painted flowers. Two good qualities, then, are offered us in the best of the variegated-leaved tulips, and we have to thank Mr. Burley for becoming the expositor of Dutch notions, and the diffuser of Dutch improvements here; for we cannot know too soon all about these novelties, which offer a quite new element for the embellishment of our conservatories in the early spring, and our gardens at the dawn of summer. Some of the varieties we have seen at Mr. Burley's are good in every respect—in leaf and flower—in form, colour, habit, readiness to comply with forcing—in all the several qualities for which early tulips are valued. Perhaps we may seek far and wide to supersede such a noble variety as *Imperator Rubrorum*, with its glaucous leaves nearly three inches across, and its finely-formed vermilion and orange-yellow flowers. But a bold sulphur or creamy stripe on the leaf is a matter of no small consequence, and if the new variegated-leaved varieties can be distributed at a rate not greatly in advance of that realised by established favourites, we can promise our Dutch friends that as fast as they can propagate them the English will buy them, and for several years to come there will be no abatement of the demand. The new hyacinths brought forward by Mr. Paul, and the new tulips brought forward by Mr. Burley, prove that the English have no monopoly of the passion for advancement in floriculture.

ANDROPOGON SORGHUM, to which Messrs Hooper and Co. directed the attention of our readers in their letter in defence of Mr. Hullett (March 23, page 130), is much more likely to become valuable as a cereal than either *Sorghum Tartaricum* (?) or *Sorghum (Holcus) saccharatum*, judging from what we know of the first and last named of these three grasses, for of the second we know nothing. Should this *Andropogon* prove to be a good corn-producing plant, Mr. Hullett will have done some good by indirectly awakening an interest in its cultivation, even though his own pet *Sorghum Tartaricum* should prove, as we still anticipate it will, to be quite incapable of ripening its seeds in any part of Britain in average seasons. We speak from knowledge of this particular plant, having frequently grown it as an ornamental grass, and as a corn-food for poultry. We have now some samples—that is to say, complete plants with their ripe fruit not shelled out—that were grown at Stoke Newington in 1859, and on examining the ears we find a sufficient amount of good grain to illustrate in a very promising manner Messrs. Hooper's recommendation. We leave *Sorghum Tartaricum* to find its level; we know nothing of it, but Messrs. Hooper have obligingly furnished us with a sample of the seed, and we hope to know all about it in due time. That it is distinct from *Sorghum saccharatum* we may infer from the difference observable in the seed, but it is a sorghum doubtless; and we can no more expect to ripen its seeds with such certainty as to become an established corn-grass in this country, than we can expect to naturalize the sago-palm or the sugar-cane. We have, in truth, scarcely any curiosity about *Sorghum Tartaricum*. If it should

No. 101, NEW SERIES.—VOL. X.

prove to be the boon it is represented, we will be among the first to give Mr. Hullett his due. The reason why we are not persuaded by his eloquence in behalf of his farinaceous protégé, is that we have got hardened to his descriptions of wonderful plants, and have never been softened by seeing any of them. But in *Andropogon sorghum* there is some hope; and we recommend those of our readers who are fond of novelties to sow a patch of it some time before the 20th of the present month, and wait patiently for the result. It is a tall robust-habited grass, producing a club-like head, the seeds in which are black and glossy. It requires a deep, rich, warm soil; and if sown in rows, they should be at least three feet apart, and the plants should be thinned to a foot apart in the rows. Whether good for bread or not, those who grow a crop need not waste it, for any animal that is partial to corn will eat it, and cattle will gladly chump every scrap of the succulent foliage, which remains green for some time after the seeds have ripened.

ENGLISH BEET-ROOT SUGAR.—The following observations on the culture of beet-root in England for the manufacture of sugar are from a daily paper: "An experiment has recently been made of growing beet-root for the manufacture of sugar in Illinois. About 400 acres of fresh prairie were planted, and 4000 tons of beet raised, which is in course of being worked up, and is expected to reach nearly 400,000lb. of refined sugar. The United States have been, like ourselves, the most important consumers of cane-grown sugar, the Continent generally having long accepted the beet as the raw material of their supply. But if the Americans and the Germans and French can grow their own sugar, why should not we do so? Beet-root is not like sugar-cane, an article only to be reared in tropical or semi-tropical countries. We raise it in England of excellent quality, and not only do we raise the crop, but of the sugar we consume about one-sixth part (according to the *Produce Markets Review*) is beet-root sugar imported from the Continent. There seems no reason why this additional branch of industry should not be added to the many enterprises of the country. While the beet has been planted for purposes of sugar-making on the prairies of the West, the cane is being vigorously cultivated in the colony of Queensland. It is estimated that upwards of a thousand miles of alluvial soil on the coast-line of that colony is in every way adapted to the cultivation of the cane. The attention of all countries seems to be directed more and more to the supply of sugar. We used to be dependent for our supply upon the West Indies, just as we were upon America for our cotton, but every day the sugar question is becoming better understood, and in spite of our scale of duties, the West Indies will be compelled to feel more and more the influence of competition, and the necessity for exerting themselves accordingly."

New Plants.

In the recent issues of the *Botanical Magazine* occur figures and descriptions of the following:—

Tapeinotes Carolinæ.—A beautiful Gesneriaceous shrub with ornamental leaves and handsome white flowers. It will be a valuable plant for the stove and for exhibition.

Angraecum citratum.—This pretty orchid is a native of Madagascar, whence it has been obtained by Messrs. Veitch. The flowers are closely set on a raceme three to five inches long; they are primrose white.

Impatiens latifolia.—An Indian perennial balsam, with large rosy purple flowers.

Clavija fulgens.—A handsome myrsinaceous plant from South America. The trunk is short, the leaves ten to fourteen inches long, and the flowers numerous on racemes four or five inches long; they are deep orange-red with yellow discs.

Mesospinidium sanguineum.—A pretty orchid, with nodding racemes in the way of *Rodriguesia secunda*, but larger and handsomer. It has been long known, but has recently been obtained and cultivated by Messrs. Backhouse of York. "It appears to be quite at home in what may conveniently be termed the Peruvian house, as meant to include the coolest and dampest section of temperate orchids, while the Mexican house would indicate a climate somewhat warmer and drier than the last, but still cool."

Barleria Gibsoni.—A pretty acanthaceous shrub from Central India; it is of neat habit, and produces handsome purple flowers.

Pteroma sarmentosa.—A superb species, well adapted for greenhouse culture; the flowers are numerous and large; the colour deep violet shading to cobalt blue.

Sarcanthus erinaceus.—An exceedingly pretty orchid, producing numerous racemes of minute flowers, which are primrose-white touched with yellow; the lip rosy pink.

Siphocampylus Humboldtianus.—An elegant plant, with bright green ovate leaves, and large tubular flowers of a bright orange-red colour.

Oncidium serratum.—A remarkable species, with fantastic flowers, which have somewhat the appearance of *O. crispum*, borne on twining scapes, which in strong plants attain a length of nine or ten feet. It is a native of Peru, and must be regarded as a moderately cool orchid.

Synadenium Grantii.—A curious euphorbiaceous shrub brought home by Captain Grant from Central Africa. It is of robust growth with thick leaves, and the inflorescence is variously coloured, green, rose, red, and brown.

Peperomia arifolia vargyreia.—A beautiful variegated-leaved stove plant, now pretty well known amongst cultivators.

Saccolabium giganteum.—This magnificent orchid has been established in this country through the energy of Messrs. Veitch, who have obtained fine plants from Rangoon. It is a stately and brilliant subject, more agreeably perfumed than *S. violaceum*, and the flowers last full three months in perfection.

Cordyline Australis.—The true *C. australis* is the commonest of four or six species that inhabit the New-Zealand group. The one formerly figured under this name, in the *Botanical Magazine* is not identical with Forster's species; the present one probably is so.

Tinnea Ethiopica.—A beautiful labiate plant from central Africa, which flowered freely in Mr. B. S. Williams's Nursery, Holloway, last winter. It is elegant in habit, with bright green ovate leaves; the flowers copiously produced in the axils or in terminal spikes; corolla dark maroon purple, showing a curious and beautiful contrast to the green of the leaves. The flowers emit a delicious violet odour.

Dictyopsis Thunbergii.—A beautiful climbing plant of slender habit, with bright green leaves, and clusters of small greenish yellow flowers.

Dombeya Mastersii.—A beautiful stove shrub, with large cordate ovate leaves, and large clusters of pearly white flowers.

In recent issues of *L'Illustration Horticole* occur figures and descriptions of the following:—

Lilium hamatochromum.—This is believed to be a hybrid. It is of Japanese origin, and is in every sense a noble plant. The flowers are of great size, the colour deep chocolate shading to black, with bright lines of cinnamon colour.

New Varieties of Gladiolus.—1. *Impératrice Eugénie*: outer segments white, with mauve stripes; inner segments mauve, with shades of pink; very beautiful. 2. *Reine Victoria*: white, with stripes of rose; inner segments white, with rosy-purple feather. 3. *John Waterer*: small, but neat and showy; orange red, with purple feather on a white base.

Rhododendron marginata punctatum.—A fine hybrid adapted for the conservatory. The flowers are of medium size, in large trusses; cream colour heavily spotted on the top petals with crimson chocolate spots; the other petals spotted on the edges only.

Larix Kämpferi.—A not very good figure of this beautiful larch, but amended is made by an able series of analytical figures by Mr. Fitch.

Gastronema sanguinea.—A superb ally of the *Hippeastrums*; the flowers elegantly formed, colour vermilion, throat yellow.

Maranta rosea-picta.—An exceedingly beautiful maranta; the leaves dark green, edged with a row of zigzag marks of a pale pink colour; the mid-rib bright carmine.

Camellia Constantin Pretiakoff.—A noble flower of large size, most beautifully finished in outline and petal; colour delicate blush deepening to delicate warm flesh.

NEW HYACINTHS AND EARLY TULIPS.

The Dutch florists appear to have lost none of their old enthusiasm and matchless skill in originating and multiplying superb varieties of certain classes of flowers. Of late they have manifested quite a revival of their historical renown, and have distributed new varieties of hyacinths, tulips, and other bulbs, with a liberality unwonted during recent years, and quite reminding readers of the history of floriculture of certain chapters that are more startling than pleasing. But there is nothing startling or dangerous in the modern revival of Dutch floriculture. The movements of the cultivators are subordinated to the demands of the market, and possibly commercial more than artistic considerations weigh heaviest in determining the course of their labours. During the season that has just closed (we mean the season of the hulk trade) the thrifty Hollanders have not met with their customary share of encouragement from English buyers. The monetary panic of 1866 had a visibly depressing effect on the hulk trade at the close of the year. Hence, possibly what we have seen in the present spring of the progress of improvement in the hyacinth and tulip rather foreshadows than fully indicates the nature of the operations that are in progress for the enriching of our collections of those most useful, most beautiful of spring flowers. But what we have seen has deeply impressed us with the fact that English cultivators are not alone in the exercise of skill in hybridizing, or of taste in selecting new varieties of florists' flowers. Mr. William Paul has brought forward a few superb new hyacinths and tulips, and a few novelties in both these classes have been shown at provincial exhibitions. But the most extensive, and at the same time most interesting, collections of novelties of this kind were some that were imported and flowered by Mr. Burley, of Albert Nursery, Pembroke Place, Bayswater, and which included several handsome early tulips with variegated leaves, varieties that we have no doubt will become extensively popular for conservatory decoration, and perhaps also as spring bedding plants. Having made notes upon these several novelties, we purpose now to enumerate and describe them, that cultivators of these things may be, through these notes, *au fait* on the progress of two most important decorative and exhibition subjects.

NEW HYACINTHS.

Lord Shaftesbury.—Single white; the spike rather loose, yet not to a fault, for on loose spikes we see all the outlines of the bells, and if they are elegant, looseness up to a certain point is a gain. In this variety the bells are of great size, and very beautifully formed, wax-like in substance, and emit a fine spicy odour. It is altogether first-rate, even when compared with the best whites in cultivation.

Blondin.—Single blue; the spike is quite full, but scarcely crowded, in size and proportion quite majestic, and borne on a stout pillar from amidst an abundance of fine bright green fleshy leaves. The bells are large, finely rounded at the base, the points elegantly recurved; the colour a most delicate shade of violet grey, at once peculiar and exquisitely beautiful. There is no variety known that can surpass this, and very few, if any, to equal it.

Prince Albert Victor.—Single red; the spike is close and solid, but finely proportioned, and of full average size. The bells are nicely formed, but in no respect remarkable for beauty, though smoother and neater than is usual with high-coloured reds. Their colour is brilliant red, with a darker stripe on each segment.

Linneus.—Single red; the spike is crowned, and the bells are small, and instead of recurving, as in the fine bells of some white and pale red varieties, the segments are incurved, and until the spike is considerably advanced they are tipped with green. Nevertheless, this is a brilliant

variety, and certain to become a favourite on account of its colour, which is brilliant crimson. It may be added to the series of richly toned varieties in which we find *Lady Sale*, *Robert Steiger*, *Von Schiller*, *Vuurbaak*, and others of the strong reds.

NEW TULIPS.

Brutus Rectifié.—This is a fine feathered variety of one of the best old bedding tulips, and well deserves attention, as vying with some of the late tulips in its splendid and tolerably correct markings. The ground is bright yellow, and the feather is hold and sharp, the colour intense crimson scarlet. This was shown by Mr. Paul at Regent's Park. All the rest that follow have been seen by us only in the nursery of Mr. Burley.

Queen Victoria.—Fine form, white ground, and rich carmine feather. There is an old white variety under this name, from which the present differs considerably.

The Bride.—Very large; petals nicely rounded at the ends; colours white with broad bold stripes of carmine.

Princess Marie.—Large; petals too long; superbly coloured; rich carmine with white base.

Beauty Supreme.—Small and neat; rich cerise, white edges.

The Circassian.—Very large and bold; rich yellow, with large, bold, fier red flame. A grand flower, and first-rate for show or decoration.

Belle Alliance.—There is a good old dwarf red variety under this name, which is largely employed for massing. The variety now before us has immense leaves that are more like the leaves of a canna than a tulip, and the flowers are small, double, dull purplish red; altogether inferior.

Maria.—Dwarf and neat; brilliant carmine red; with white stripes; first-rate.

Golden Standard Variegated.—The leaves superbly margined with pale sulphur; flowers gold yellow; a fine variety.

President Lincoln.—A grand double flower; deep red edged with orange; fine hold leafage; first-rate.

Silver Standard Variegated.—Leaves elegantly edged creamy buff; flowers rich carmine with white stripes. This is unquestionably a variegated-leaved form of the old *Silver Standard*, but in becoming variegated a new break has occurred in the flower, which is more heavily coloured than the old variety.

Golden Standard.—Grand habit of leaf and flowers; the colours are rich gold and hold red flame, heavily laid on.

Butterflower.—A most beautiful clear yellow self, quite distinctive and eminently desirable.

Edouard d'Argent.—Habit objectionably tall; leaves finely-edged creamy white; flowers double, pale lilac rose.

Feu d'Empire.—Leaves edged with clear sulphur-yellow, and the flower superb in size and form, gold base and brownish crimson flame; a very fine tulip.

Double Proserpine.—We have here the beautiful violet and rose colouring of *Proserpine* in an exceedingly double flower. It is certainly a valuable addition to the double class; but its name compels us to reflect upon the great difference in respect of grace of form between good singles and the best doubles. The first are as flowers, emblems of elegance; the second as puddings, emblems of quantity.

Lac Bonifol.—The leafage of this variety is superbly variegated with a broad margin of pale sulphur or cream-colour; the flowers single; colours purple, red, and white, in not very distinct arrangements.

Pallas.—An extra fine variety; lively yellow and gold. Quite new, and extra good in habit, form, and colour.

Duc Van Thol Rose Bonté.—Very early; yellow and crimson, striped and flaked, like the family to which it belongs; very dwarf and easy to force, and a very good addition to the already long list of sports of the "Duc." S. H.

NEW CHRYSANTHEMUMS.

The following are the names and descriptions of the new varieties offered this season by Mr. Salter, of Hammersmith:—

LARGE FLOWERS.

Ali Baba (Salter), red with golden black, very double and large, incurved show flower.

Cadie's Perfection (Cadio), bright red with orange back, very double, and finely incurved.

Countess of Warwick (Salter), sulphur white or primrose, large and finely incurved, of excellent habit and foliage, a beautiful show flower.

Dr. Lindley (Salter), large dark orange with amber centre, broad incurved petals, a first-class show flower.

Faust (Pethers), bronzed crimson purple, incurved and very full, extra fine dwarf habit and foliage, a great acquisition to the specimen class.

Fingal (Davis), large rose violet with lighter back, very double and symmetrical, petals wide and finely incurved, a noble show flower.

Isabella Bott (Pethers), delicate pearl white tinted rosy lilac, very double, large and conical, with finely incurved petals, having a wax-like appearance, which, together with fine form and habit, renders it a perfect gem.

Lady Talfourd (Salter), delicate rose lilac with silvery back, petals beautifully incurved, and of a shell-like form, very double, and of medium size, one of the most symmetrical flowers ever offered, a lovely plant equally suitable for specimens or cut blooms.

Lord Stanley (Salter), large orange amber, finely incurved.

Mrs. Heale (Heale), pure white, very large and of exquisite form, a *fac simile* (except in colour) of the beautiful and highly-prized "Princess of Wales," of which it is a white sport.

Ossian (Pethers), large rose, incurved, very double and free, an attractive conservatory plant.

Prospero (Salter), dark violet purple, very full, incurved and free.

Purpurea Elegans (Salter), rich purple violet or crimson, with half-incurved petals, of medium size, very double and free, a scarce and most attractive shade of colour, and both for specimens or the conservatory a great acquisition.

Rosa Mutabilis (Salter), delicate peach-voined rose, broad incurved petals, dwarf habit, and fine for cut blooms or specimen plants.

William Edward (Salter), canary yellow with short, stiff, and finely incurved petals, very full, and first-rate show flower.

Yolande (Salter), creamy white tinged with lilac, broad incurved petals, a very fine and choate flower.

POMPONS.

- Aglai*a (Poole), blush with very high white centre, a fine free flowering anemone.
- Christabel* (Salter), bronzed rose and fawn centre, dwarf and fine.
- Little Creole* (Salter), brown orange, very dwarf compact habit, and free.
- Little Kate* (Salter), blush with primrose centre, fine form and compact habit.
- Madge Wildfire* (Salter), vivid red and large golden tips, distinct novel colour and very attractive.
- Peri* (Salter), dark yellow and red points, very dwarf and free, flowering pyramically.
- Saint Michael* (Salter), very bright gold, equal in colour to "Jardin des Plantes," full size, dwarf habit and very fine.
- Stella* (Salter), rosy purple and high-bronzed centre, a fine full-sized anemone.
- The Countess* (Salter), blush tinted lilac, a beautiful little pompon, flowering in compact bouquets.
- Zobeide* (Salter), light rose and high centre, a fine free anemone.

NEW BEDDING POMPON.

Louise Honnoraty (H.), dark rose, small, free, and of exceedingly dwarf bushy habit, from ten to twelve inches high, quite a gem.

The following are offered by Mr. Forsyth, of Stoke Newington:—

LARGE FLOWERS.

- Mrs. Geo. Rundle* (Morgan), pure white, very high centre, close and compact; one of the most beautiful incurved flowers ever offered.
- Dr. Sharpe* (named after the raiser), fine magenta; unequalled for specimen growing (a novel colour much wanted).
- Hetty Barker* (Slade), fine pearly white, full, free, and early; a fine incurved show flower.
- Mrs. Heale* (Heale), described above.

ANEMONE.

Princass (Howe), a sport from Prince of Anemones; certainly the finest pure large white Anemone ever sent out.

POMPON.

James Forsyth (Forsyth), colour fine orange crimson; a most useful, distinct, early, and free flowering Pompon.

The following is offered by Mr. Chapman, of Crescent Road, Great Warley, Essex.

Alfred Chapman (Chapman), a neat Pompon; flowers medium, perfect in form, blush deepening to soft pink; most beautiful.

MR. CHARLES TURNER'S NURSERY, SLOUGH.

This nursery enjoys a world-wide reputation for its extensive collections of the choicest plants of all kinds, and its masterly treatment of subjects sent to exhibitions. It has been said that florists' flowers have no general home—that they are to be found only in the small gardens of a few enthusiastic amateurs, who are as archæologists in the regions of Flora—and that their day is altogether past and gone. There may be a glimmer of truth in these statements, for the bedding mania has driven many good things out of cultivation for the present; but THE GARDENER'S MAGAZINE and THE FLORAL WORLD, by their persistent and consistent advocacy of things beautiful and interesting—by their happy and faithful representations of the intellectual features of decorative gardening—will certainly keep within the pale of recognised favourites many beautiful plants that have been sadly threatened with extinction. But I reflect upon the assertion that this and that are going out of cultivation, and in the midst of my reflection I enter this nursery, and I presently begin to doubt if there is any truth at all in what I hear of the decline of florists' flowers. Moreover, I am not here many minutes ere I feel myself on charmed ground; for I am not only in the nursery of Mr. Turner of Slough, who makes a bright mark in the annals of every first-class flower show, but in the midst of florists' flowers—in the midst of collections so vast that every good flower is fully represented, and the stock appears to be enough to meet all the demand that must arise when the revival that is promised has really dawned upon the floral mind. Well, I propose to look about me, make my purchases, and carry away in my mind a few notes of what I have seen. Now I shall begin by saying that nurseries differ in many respects, and no two are alike. There are two peculiarities about this nursery. It is, in the first place, remarkable for cleanliness. Whichever way I look I see everything bright; and, to use a homely simile, one might eat one's dinner off the floor of any of the plant houses, or even off the potting benches, without being vexed with a particle of grit. I had heard people say, "What a clean place Turner's is!" but the saying conveyed to me no such idea as I derived from a sight of the place, which is like a nursery in a picture-book or pantomime, save and except that it is a real nursery—but I mean as respects the neatness, order, and finish of everything. And the word "order" reminds me of the other peculiarity, and that is the admirable arrangement of the whole scheme. Wherever you take your stand to look about you the surroundings are all of a kind. You do not go out of a steaming stove into the midst of slush, or into a confusion of broken pots and packing stuff, as in some nurseries I could name; but the whole affair is ordered like the chapters of a master treatise on any subject, and objects that are nearest to each other are always in some way related. I would beg of all our young gardeners to bear in mind that Mr. Turner is not only a hero at exhibitions, but a master of small details: he knows how a stage of pelargoniums ought to look, and he knows where the sticks and ties, and the pots and the crocks should be; he is like the general of an army—he can lead in a great advance, and he can at the same time consider the health of his troops and the care of their ammunition. We ought to learn from such examples that the study of trifles, when demanded by utility, is consistent with the working out of a lofty ambition.

Bricks and mortar are increasing at Slough, as everywhere else in the neighbourhood of London, yet there is much true rurality visible on every hand, and the atmosphere is most salubrious, which is a circumstance favourable to the extensive collections of florists' flowers, which need a pure air, especially where they have to be propagated largely as a matter of business. And it adds much to one's enjoyment of a visit to this charming place that we are removed from the din and roar of traffic that we hear so much of in London; in fact, it is but a short walk from the railway station to the nursery, and the sudden quiet and rurality are as magic. I found my way into the nursery through the seed shop, where many hands were busy in packing

seeds for customers, and it was evident at a glance that plants are not the only subjects of demand here, for an immense activity prevailed in the seed department. Mr. Turner has done quite as much for our good in this part of his business as in the growing of specimen plants, and his bold speculation in new varieties. It should be remembered that we are indebted to the good offices of the great cultivator at Slough for the valuable series of improved varieties of peas raised by Dr. Maclean of Colechester, as well as for many other most excellent things that have been distributed through the same agency. The Cottager's Kale, one of the few Brassicas that withstood the late terrible winter, was a protégé of Mr. Turner's. But let us go on and find our way amongst the plants.

One of the most interesting of the many structures is that called the "long house," now filled with a stock of young pelargoniums, which are as clean and healthy as can be imagined, and in a state and shape suitable for specimen growing or conservatory purposes, having been stopped and encouraged to break nicely, showing a free growth of side branches. Most of them were in four and five-inch pots and quite ready, when transferred to the purchaser, to be shifted into larger pots, by which means they will make unique little flowering specimens this season. From this house we pass on to the houses in which are growing the specimen plants that are to adorn our forthcoming exhibitions of 1867. The building being commodious, the plants are allowed plenty of room for light and air, with the view of equalising their growth, and as they are somewhat elevated, the spectator has an excellent opportunity of observing their general configuration and dimensions; and the mode of training pursued is such as will produce the best effect when staged at an exhibition. I owe many thanks to Mr. Frost, the manager of this department, for the courteous manner in which he replied to my inquiries respecting the various properties of the pelargonium. I found the following to be favourite varieties both for exhibition and decorative purposes, and of most of them large stocks were grown, to meet the demand which is great at this time of year: *Show*: *Alba formosa*, *Alabama*, *Atalanta*, *Ariel*, *Bacchus*, *Beadsman*, *Boniface*, *Caliban*, *Charles Turner*, *Cœur de Léon*, *Conflagration*, *Decision*, *Display*, *Elegans*, *Empress Eugénie*, *Fair Rosamond*, *Fairest of the Fair*, *Festus*, *John Hoyle*, *King Arthur*, *Lady D. Canning*, *Lilacina*, *Lord Clyde*, *Leviathan*, *Mariana*, *Mary Hoyle*, *Nabob*, *Norma*, *Osiris*, *Peacock*, *Pericles*, *Pulchra*, *Queen of the Gipsies*, *Rose Celestial*, *Sir Galahad*, *Sir Colin Campbell*, *Sanspareil*, *Talma*, *Vestal*, *Viola*, *William Hoyle*. *French*: *Achille*, *Archimidee*, *Cuvier*, *Dr. André*, *Dr. Blanchett*, *Duchesse de Morny*, *Empereur des Pelargoniums*, *General Fleury*, *Guillaume Severeys*, *Lady Franklin*, *Madame André Dreux*, *Madame Corbay*, *Madame Rendatler*, *Marquis de la Ferté*, *Neptune*, *Octavie Malet*, *Pliny*, *Rubens*, *Théophraste*, *Victor Lemoine*. *Fancy*: *Acme*, *Anne Page*, *Blair Athol*, *Carminatum*, *Cloth-of-Silver*, *Clytie*, *Crystal Beauty*, *Godfrey Turner*, *Hebe*, *Lady Boston*, *Maroon*, *Miss in her Teens*, *Modesta*, *Mrs. Ford*, *Princess Helena*, *Princess of Prussia*, *Silver Mantle*, *Venus*. This may appear to be a long list, but it does not comprise a tenth part of all the varieties that are grown here. Strange to say, although I have selected the most popular kinds, and arranged them alphabetically, a selection made from them, by taking every third or fourth or fifth name, according to the number wanted, will secure as much variety of colour as if we were to go through the lists again, and classify them in colours for selection.

From the specimen pelargonium house I went on to a range of low span-roofed houses. In these I found more pelargoniums, chiefly of the spotted kinds, most of them showing well for a fine bloom. These have been grown expressly for early flowers, and consist largely of the French varieties, which are earlier than the show kinds. In one of the houses of this range I saw a grand collection of variegated and other kinds of zonale pelargoniums, and, again, in another house a vast assortment of the nose-gay race. I was gratified to learn that large stocks are being prepared of *Duchess of Sutherland*, *Lady Constance Grosvenor*, and *International*, three of the most striking of the new varieties shown last year, and which have been described in the "Garden Oracle" as amongst the finest nosegays known.

Bedding plants are grown here in immense quantities, and they may be seen in all stages from myriads of mites, just pushing out roots into comfortable beds of silver-sand in propagating houses, to thumping plants, almost bristling into bloom, such as in the trade would be called "nice young stuff." The verbenas were particularly healthy and strong, and of geraniums the quantity was enormous. The long rows of frames and pits were all filled with hedging plants, and it being a cold day and dusk approaching, they were all covered with mats to keep them from danger. One thing I noticed as worthy of remembrance—that there were many hundred pots of the glorious *Lilium auratum* of various sizes; these were plunged beneath the stages on each side of one of the span-roofed houses. The bulbs are treated just as was described by Mr. Prosper in the Magazine a few weeks back, and as a rule they are forwarded gently, no attempt being made to force them. This is a great convenience to buyers, who during the spring months can have bulbs just started into growth, but yet not advanced beyond the production of an inch or two of the rising crown, in which state they travel safely, and there is no risk of the bulb refusing to start or proving to be dead, as may sometimes happen with bulbs that have performed a long voyage. They have here several good varieties of this liliun; indeed, in respect of sportiveness, it appears already to have taken its place amongst florists' flowers, for there are at least a dozen (probably more) distinct forms of it, some snow-white, others having red instead of yellow stripes.

We were now conducted to the early rose house, and here I spent a very pleasing and instructive half-hour in surveying the plants and conversing with the manager of this department on their respective qualities and adaptations for the purposes for which they may be required. The health and cleanliness of the plants visibly contributed to the production of the fine buds I there saw, many of which were showing colour; but as soon as they are expanded they are cut, as the firm has a great demand for cut blooms. The specimens intended for the spring exhibitions were all trained, and had their buds quite prominently developed. With them, as with the pelargoniums, plenty of open space was allowed from plant to plant. There is another house in which some large specimens are but as yet only just pushing into growth, being but little forwarder than roses in the open ground.

Having bid farewell to the roses, we now arrived at a spacious house, the inmates of which are those gigantic plants of azaleas which annually excite the wonder of the crowds who behold them at our London flower shows. With the exception of Mr. Veitch's collection at Chelsea, there are not, I believe, anywhere plants to be found to match these monsters, either in magnitude or perfection of training, in the known horticultural

world. I observed to the person who superintended their training and culture, "What would our country cousins say when informed that only two of these plants could be packed in a van measuring 14 feet by 8 feet?" The circumference of some of them was upwards of 18 feet and in height from 6 to 7 feet! In fact, they are unique for size, splendour, and perfection of cultivation. The mode of training adopted may be styled crinoline fashion, with cross bars at intervals to support the hoops in position. Although it has a very formal appearance, they say it is far more beneficial in preserving the vigour of the plant than when they had to resort to the use of numerous stakes. There is also another house devoted to the growth of lesser-sized specimens, and to the cultivation of the newer and other varieties for sale. By way of finishing my view of the nursery, I took a stroll through the conservatory or show house, which was gay with forced and early spring-flowering plants, all of them in what will be understood as in Mr. Turner's style of treatment. In thus concluding my pleasing but instructive visit to this nursery, I wish to thank the heads of the several departments for their very courteous and obliging manner; and I would only say, by way of an appendix, that it would afford the means of edification to all engaged in gardening, if they would pay a visit now and then to such nurseries as are eminent for the superior growth of certain classes of plants.

JOHN F. M'ELROY.

BEDDING GERANIUMS.—No. XXXVIII.

My friend Horatius says with a quiet sarcasm, *Curtæ nescio quid semper abest rei*; and I confess I am in dreadful want of a little batch of plants that appear to be indispensable to human happiness,—they are geraniums of the proper zonale type, with true florists' flowers; the top petals as broad as the lower ones, the outlines circular and smooth, the substance that of camellia petals, the colours good; the plants altogether emblems of vegetable nobility. I remember, to be sure, the very sage observation of the same delightful person, *Denique non omnes eadem mirantur amantque*, and it does not follow at all that any of our readers should be in precisely the same condition of longing, or wish to be directed into any such channel of exhaustless wants. But on the speculation that there may be a few interested in the same hobbies as myself, I will hastily call over the names and the qualities of the plants, just as one might toss sixpences from a carriage window at the risk of their being picked up by appreciative fingers, or as, a week ago, I threw a handful of flowers into a lady's lap all at a venture, and was rewarded by the loveliest smile of approbation ever seen on this side of heaven. To provide for every appetite and to anticipate every taste are things impossible; but to say so much is only to repeat in prosy terms that which Quintus Horatius Flaccus sets forth in his second epistle (Lib. 2) as bearing upon the whole philosophy of life:—

*Gemmas, marmor, ebur, Tyrrhena sigilla, tabellas,
Argentum, vestes Getulo murice tinctas,
Sunt qui non habeant; est qui non curat habere.
Cur alter fratrum cessare, et ludere, et ungi
Præferat Herodis palmatis pinguibus; alter
Dives et importunis, ad unbram lucis ab ortu
Sylvestrem flammis ac ferro mitiget agrum;
Scit Genius, natale comes qui temperat astrum,
Naturæ Deus humanæ, mortalis in unum—
Quodque caput, cultu mutabilis, albus et ater.*

I therefore leave every one of our friends to the enjoyment of perfect freedom, that is, if guided by genius and governed by the stars, and circumstances consistent with freedom at all, and content myself with announcing that at the head of my list of desiderata for 1867, are the three large-flowering zonales raised by Mr. Groom of Ipswich, who has entered into this hobby with an enthusiasm worthy of so good a cause. One of those three is so good that it might be offered the first season at a guinea a plant, with perfect justice to the buyer, if the raiser could be content with the figure, as I presume he might be. Let me briefly describe it. The habit is robust but compact, freely branching and leafy, so that it soon makes a plant, and there is much to look at. The leaves are of medium size, orbicular, and slightly lobed; the zone broad, sharply defined on the inner boundary; the colour nearly black, with a disc and margin of deep grass-green. The flowers of course are the main feature. They are larger than crown-pieces and quite as flat; the edges smooth and sharp as if stamped in cardboard; the petals are one full inch wide, and they overlap so freely that the circumference of a good flower does not exceed six inches, but every one will make that measure in a well-grown truss. If there is any difference in the breadth of the several petals, it is this: that the top petals are the broadest, sometimes measuring $1\frac{1}{2}$ inch from right to left, and the trusses will usually measure 5 to 6 inches in diameter. The colour is a kind of dull solid pink, it may be a reddish pink or a pure pink; it is impossible to find terms for all the shades of colour we meet with in nature, and I can perhaps best describe this as Beauté-du-Suresne colour with a slight wash of red added, and with not a trace of white in the top petals. It only remains to give the name, which is *Miss Martin*. Whoever the lady be, she never need regret having had so noble a flower associated with her name. I believe it for the present to be the best variety for 1867. Next to this in the same series we have a red: it will by some be called scarlet, by others crimson; the proper designation is, in my opinion, *Red*.

Now we have very few red geraniums: Rubens comes near it, but is not true red. The rule seems to be that nature mixes so much orange with the red as to make it scarlet, or so much indigo as to make it crimson, or subdues red and blue together into the elegant innocent-looking compound we term pink. Here is no trace that I can discover of added blue or yellow, and we have the very colour for which in former papers of this series I have uttered many expressions of longing. But let me not forget the quality: a great round flower, thick like velvet, smooth as marble, the petals an inch wide and overlapping, the truss immense, the leaves boldly marked with a brownish olive zone. The name of this is *Sir Fitzroy Kelly*. No. 3 in the series is a charming dwarf white, with flowers like White Perfection, and I am inclined to believe broader in the petal, and with a finer finish. Here, indeed, appears to be a perfect bedder, and if it has a good season to make its *début* it will become popular; but a bad season may do for it, as many a good thing has been done for—that is, do for it in the popular meaning of the term, for the success of a bedder depends very much on first impressions. The leafage is very neat and abundant, with very dark rich zone shaded black and chocolate; the flowers come in good trusses, and are pure white, without a trace of colour. Whether they will keep white during a term of six weeks' torrid weather we have yet to see—also if we shall have torrid weather any more in this country. We have tasted the cold lamb minus mint-sauce of the month of March, and while I write this the lion is roaring, and looking ridiculous, with sleet on his mane, which is now no emblem of main-force. The name of this No. 3 is *Floribunda alba nana*. The plant is better than its name, and will do credit to my recommendation.

I now turn to Mr. George Smith's list, remembering that in Chieftain, Sir Robert Peel, Great Eastern, and Christabel, last year, he stood bravely for the florists, and justified those friends of his who aver that he never sent out a bad thing. Now he offers seven zonales, and I pitch upon *Warrior* as the best of them. This is a true scarlet, of fine quality, and the outline a true circle, the petals extra broad and stout, the leaves faintly marked with olive zone, the style generally quite soldier-like, brave, and handsome. *Hector*, in the same list, is also scarlet, of a deep, heavy, rich tone; the leaves have a dull greenish zone; the habit first-rate. We shall have to call this *Smith's Hector* hereafter, to distinguish it from Bull's *Hector*, which is a charming variety with puce-coloured flowers.

The next I note as a desideratum is *Pink Globe*. This was raised by Mr. Windsor, and is not to be confounded with one bearing the same name from the seed-bed of Mr. Frost. You will find the exact truth in the "Oracle," where Frost's *Pink Globe* is described as "a commonplace pink," and Windsor's as "leaf large, zoned, large trusses of pink and white flowers; fine." I repeat the last word, FINE, and pass on to another series, but without forgetting that somewhere there is a pretty seedling of Mr. George Smith's called *Lillo*, about which I shall inquire when I next meet my worthy friend.

From Messrs. Downie, Laird, and Laing's set I should select *Fair Helen*, a very beautiful large-flowering variety, which reminds one of the prevailing muslin-like style of the fancy pelargoniums, the colour being blush-pink, and the flowers most abundantly produced. *Lord Lyon*, from the same, will make both a bedder and a pot-plant; it is not A 1 for the florists, but makes amends by peculiarly useful qualities, being a good grower, and most profuse of flower; and the flowers are as good as those of *Attraction*, which is a good type of an intermediate race—good enough for pots, yet never too good for beds. If this were put in competition with *Attraction*, it would beat it at every period of the season by its vastly more abundant flowering; so it is pre-eminently a variety for the people. *Mrs. Menzies* is first-rate in form and character, and the first of the salmon-class we have met with in this summary: the colour is clear rosy-salmon, the form is perfect, and in this respect it is especially worthy of notice, because the best salmon flowers are generally rather inclined to narrowness of petal. Last in this series, but not least in merit, is *Sambo*, a splendid thing, though it is but a scarlet. The form is in accordance with the most finished type of a florists' flower; the truss large and globular, the colour intense glossy scarlet, quite novel in tone, though the term scarlet is so commonplace in this connection.

Let us now look at Mr. Salter's lot. Here I begin with *Aurora*, a showy variety with vermilion flowers and properties nearly perfect—a fine thing for the conservatory stage. *Phœnix*: green leaves with sometimes a trace of a zone, the flowers nicely formed, top petals scarlet, lower petals scarlet shaded crimson. *Pink Pearl*, large, round, and smooth; colour a delightful shade of pink, with white spots on top petals; the leaves dull grass-green. If I had not resolved to speak of such only as are first-rate for pot-culture, I should add here *Queen of Denmark*, a capital dwarf-habited variety, which quite supersedes Madame Barró. Mr. Salter says it is without the white blotch; but did Madame Barró ever have a white blotch? If it has, or had, my memory is failing;

for the present I hold to the belief that it is the most self-coloured of all the pinks.

Next I turn to Messrs. F. and A. Smith's lot, several of which I flowered at home last year. There are some good things here in the broad-petal way, and some new things too, as, for example, *Queen of Beauties*, a painted flower, the predominating hue cerise, deepening at the base to vermilion, and then giving place to a white eye. The flowers are large and round, and in huge trusses. A well-grown specimen of this will have a remarkable appearance. *Magnificent* is grandly built, the trusses noble, the colour brilliant scarlet. *Perfection* is in a new shade of colour, a mixture of pink, cerise, and salmon; as to form and all the rest of the properties, equal to anything known. *Clio* is a lady's flower, of most chaste colouring and elegant construction: the colour is orange-salmon edged with white or blush. I think *Amelina Griseau* must at last give way before this beautifully painted flower. In form and truss first-rate. Add to these, if you are not yet satisfied, *Eclat*, a very showy scarlet of the finest form, which also answers, and is first-rate, for bedding. *Cynosure*, superbly painted, according to the prophecy in a former paper of this series, blush-white with vermilion centre. *Masterpicce*, cerise glowing up to flame-red; and *Mr. Bowley*, brilliant cerise, and all that could be desired as to form even by an auricula grower.

As no collection is complete without a few of the best of the double flowers, I must name a few for present purchase; and as many collectors of zonales have not yet, because of their high price, ventured into this region, I shall not be so strict as to the newness of the kinds brought forward. The old Roman sages had a proverb, *Ignoti nulla cupida*—"no desire is felt for that which is unknown;" but the case is altered the moment we have heard of something that is represented as affording delight to some section of humanity. So with the doubles: many country growers know nothing of them yet, but they must have felt the kindlings of desire. First then I name *Martial de Chanflour*, *Triomphe de Clermont*, and *Triomphe de Gergoviat*, as identical; and I think we cannot do better than know this variety by the name under which it was first published, that is *Martial de Chanflour*. This is a nice variety, though it varies much. When poorly grown, the flowers are chaffy and quite semi-double; when well grown, they are fashioned like a double Chinese primula, and the colour is a fine deep vermilion red. Hitherto the temptation to grow it poorly has been strong, for everybody has wished to seed it, and the likeliest way of doing that is to keep it on a hot shelf in the full sun, in a starved condition as to soil and water. But grow it in a mixture of equal parts loam, leaf, and rotten dung, with a good proportion of pounded oyster-shells and sharp grit added, and give the hottest shelf in the house all the early part of the season, and when it blooms late in the summer the flowers will be fine. *Triomphe de Thumesnil* is a remarkable geranium; the most remarkable of all the doubles, and quite essential, not only to see, but to be talked about. The flowers number fifty to seventy in a truss; the petals are as large as in the single kinds, and there are about twelve in every flower; the colour is rosy violet shaded carmine. You may now obtain a plant of this for half a guinea; can there be a cheaper floral joy? I should think not, but, as remarked above from Horatius, tastes differ, and Persius (4th satire) gives us the philosophy of the case in a most harmonious couplet:—

*Mille hominum species et rerum discolor usus
Velle suum cuique est, nec voto vivitur uno.*

Gloire de Nancy, of Lemoine's, flowered finely last year, and was gloriously double, and the best double undoubtedly of all that were sent out prior to 1866: the colour is a deep rose-red of a most pleasing shade. Still better is *Surpasse Gloire de Nancy*, which has larger flowers than its parent (for this is a seedling from *Gloire de Nancy*); the form is fine, and the colour brilliant rose carmine. This "Surpasse" you may obtain for half a guinea, so at least Mr. Salter tells me, and it is down in our list for this season's purchase. *Capitaine l'Hermitte* is another good one, the habit peculiarly dwarf, and the flowers more abundantly produced than in other doubles. The colour is rose-pink with crimson shade. I fully believe this will be a bedder—we want double bedders to obviate the nuisance of free seeding—and all who can afford to give this a trial out of doors should do so in 1867. There remains but one more, and that is *Auguste Ferriere*, one of the first of the double series, and now pretty well superseded. But there can be no harm in throwing it in at the end, for it will only cost a couple of shillings, and it is the most likely of them all to give a few seeds, every one of which will be worth a crown at least.

S. H.

SWIFT AND THE PEACHES.—Swift often coined proverbs to answer his own purposes. When he was one day walking with some friends in the garden of an avaricious old man, who was very particular about his peaches, he suddenly stopped at a standard tree, and exclaimed, "It was an old saying of my grandmother's, 'Pull a peach when it's in your reach,'" which he did, and the example was followed by all present.

ROSES AND ROSES.—No. V.

O P Q treated himself a short time since to a set of the first series of THE FLORAL WORLD, in order to read with care the series of papers on roses which I contributed to that work from 1858 to 1865. One of the first things that struck him was a suggestion for carpeting the ground with rose-blossoms, and upon this subject he asks for further advice. I dealt with him as I deal with you, in the plainest possible manner, saying that if I were to write fifty essays on carpets of rose-flowers, I could not do better for lovers of roses than I have done already in "The Floral World" and in "The Rose Book." There are people who like to hear the same story over and over again. There are some little friends of mine who beg me, every time they can fix me in an easy chair, to tell the story of Marmontel and the golden violet of Toulouse, though they have heard it a dozen times already, and actually anticipate me in some of the details, as, for example, when I say, "he saw through his tears the arms of an aged man stretched towards him," they interpose with much hurry, "That was Father Molasse." So I suppose, if I go into this matter now, some of our friends, and O P Q amongst them, will ejaculate at certain points, "The old wood you cut away, yes"—"peg down the long-rod, yes"—"like long-rod vine-growing, eh?" &c., &c. However, here goes. You require, in the first place, a broad space on which to make the display, and there is nothing so suitable as a slope, say the face of a bank, rising very gradually; a steep bank is quite unfit, because the summer rains would escape from it, but a very gentle slope will catch the summer rains. On the side of a promenade is a capital position, and I should prefer to make the rear boundary of the bank an irregular plantation of evergreens—something in the way of the subjoined arrangement, in which you must make allowance for the supposed undulating line, which is the best the printer's types will do. In the actual working out of the scheme we should draw that line in flowing curves, varied with a few bold prominences, and at those prominences some suitable specimen trees would be planted. In the front line there might be a narrow ribbon, consisting of *quiet colours*, to finish the work—such things as *Cerastium*, *Golden Balm*, *Viola cornuta*, *Viola lutea*, *Oenothera prostrata*, white *Verbena*, *Heliotrope*, and *Ageratum* would be suitable; but no scarlet or rose or purple should be allowed there.

Background of mixed shrubs.

Roses pegged down.

Ribbon planting.

Walk.

The ground for the roses should be thoroughly well prepared. To every space of 200 square feet one good load of half-rotten dung should be allowed with deep digging, and in the case of clay as much leaf-mould as the proportion of dung should be added, if possible. As to the planting, there must be a little thought before hand whether the colours are to be harmonised by rule or by accident. I never say any more than I can help on matters of taste, always desiring my friends to please themselves; but if any body wants to know how I should arrange the colours, I have to say I should not arrange them at all; I would, if in any perplexity, call in a blind man and tell him to take the roses at random, and place them all over the ground at a yard apart every way. But the sorts must be thought of, for we cannot proceed without suitable plants. Now, the more they are mixed the better, I think: we want *Teas*, *Noisettes*, *Bourbons*, *Perpetuals*, and for the front part of the planting some of the *Bengal roses*. The rule in ordering should be to give the preference to those that bloom abundantly and grow freely. At the end of this paper I will give a list of sixty that will serve for this sort of work for this season, and for at least ten years to come, no matter how many good roses may in that time be introduced. Plant them a yard apart; if they are *Manetti roses*, plant deep enough to cover the work at least two inches, and you may practise notching, as taught in "The Rose Book," to quicken the formation of roots above the work. But if you can obtain the necessary plants on their own roots, do so, even if you pay three times as much for them. Having planted them, and trod them in firmly, let them grow as they please the first season, keeping the ground clean the meanwhile; and if the piece has a poor appearance, sow in the intervals between the roses a lot of showy annuals. In the following winter, during dry weather, prune them and prepare them for the next season's work. You will find them to consist of hard wood, on which flowers were produced, and young strong rods of the previous year's growth. You are to cut away from the very base as many of the old

shoots as you can spare. If you can cut them all away the better, but you must save enough new and old to cover the ground when they are pegged down; and in some cases old rods must be kept to flower a second time, just as in the long-rod system of grape growing a rod is sometimes fruited a second time. Having removed with the knife as much of the old wood as you think you can spare, proceed to shorten the longest of the young rods. As a rule, you may take off a fourth or fifth of their length. The next thing to be done is to lay down over the whole piece full three inches depth of half rotten dung; after which there will be nothing more to do till the beginning of March following; then have ready a great heap of strong pegs. I have never had any difficulty in finding stuff for pegs amongst the prunings of trees; every peg should be a foot long, and should end in a fork. Those not used to cutting such pegs will soon learn how to do it by five minutes spent in experiments, and at the worst they may buy a few bundles of new pea-sticks, and make pegs therefrom *ad lib.*, and the leavings will still do for staking peas. With these pegs fix the long rods to the ground, bending them this way and that way, with a view solely to cover the ground equally, not with a view to spread out the branches of any particular rose, according to system; for it matters little how the branches cross each other, they will all be cut away the next year, and when the roses are in full growth, the pegs and rods will be alike hidden by leaves and flowers. I shall not dwell upon the result of all this; I leave it to your imagination, if you know nothing about it; and to your pleasures of memory, if you have ever carried out the plan in a spirited manner; it will suffice to say that the ground should be quite covered with roses and green leaves.

As the flowering season comes to an end, new rods will be rising freely. Let them rise. Some of them will attain a height of ten feet, most of them will make five to seven feet of growth. In the autumn you may find it necessary to thin out some parts of the plantation, and actually to leave the stools two yards apart. At all events, you must now cut away all the wood that flowered, bearing in mind, however, to keep it to flower a second time in cases where there is not enough of new wood to take its place. You must next lay down a coat of manure, and you must then wait till the first week in March, and peg down the long rods as before. Thus the wheel turns round. If you want to introduce new roses, you have simply to lift so many old ones to make room for them. If you want to make a great change, you can replant them in lines, curves, or clumps of separate colours. But here again we come upon matters of taste, on which, for the present, I shall say no more. I am bound to say, however, that though I have seen many examples of this mode of displaying roses, I have seen only three good examples of it, except such as I have carried out myself, both at home and in gardens that I have laid out and planted for others. I have seen it well done by Mr. Chitty, who gave an account of his mode of procedure in the third volume of "The Floral World" (p. 103). I have seen it well done in the garden of Miss Burdett Coutts at Highgate, and I have seen it well—more than well, grandly—done in the garden of Mr. C. J. Perry of Castle Bromwich. I can tell you how to do it badly. Choose poor ground, and humbug it—that is, scratch instead of dig—and manure with washed-out stuff that has been lying about for years, as the people in a certain part of Britain make their soup from

bones tied to a string, and that are lent about from house to house for years together. To complete the process, select weak wiry growers, and having done it, move away. Now for the sixty, all of them adapted for the work, and good autumnal roses.

Hybrid Perpetuals.—Admiral Nelson, Alex. Beechmeteff, Anna de Diesbach, Anna Alexieff, Baronne Prevost, Cardinal Patrizzi, Centifolia Rosea, Charles Lefebvre, Charles Margottin, Colonel de Rougemont, Deuil de Prince Albert, Duchess de Medina Cœli, Empereur de Maroe, Eugène Appert, Exposition de Brie, General Jacqueminot, General Washington, Glory of Waltham, John Hopper, John Grier, Jules Margottin, Louise Darzens, Madame Alfred de Rougemont, Madame Knorr, Madame Charles Verdier, Madame Elise Vilmorin, Madame de Cambaëcrès, Madame Gustave Bonnet, Madame Victor Verdier, Madlle. Betsy Haiman, Madlle. Berthe Levêque, Maréchal Souchet, Paul de la Meilleray, Princess Mary of Cambridge, Sénateur Vaisse, Souvenir de Lady Eardley, Victor Verdier.

Hybrid Bourbon.—Louise Odier, Modèle de Perfection, Acidalie, Gloire des Rosomenes, Queen, Sir Joseph Paxton, Souvenir de la Malmaison.

Noisette.—Celine Forestier, Desprez à Fleur Jaune (otherwise called Jaune Desprez), Maréchal Niel, Triomphe de Rennes.

Tea.—Alba Rosea, Devoniensis, Gloire de Dijon, Naresse, Niphotos, Président, Vicomte des Cazès.

Bengal (for front line).—Archduke Charles, Fabvier, Marjolin du Luxembourg, Mrs. Bosanquet. The pretty *Noisettes* Feltenberg and Aimée Vibert are also well adapted for the front line.

O P Q is always in a pretended perplexity about the proper time to plant roses. I say pretended advisedly, because no one can read a page of any respectable book upon the subject without learning something substantial under that head. As to the planting of such a bank as I have herein suggested, the month of May is the best time, or if the bank had been made ready a month ago, now would be the best time, provided the roses could be obtained in pots, and had never known the taste of artificial heat. And in an extreme case, I would as soon take up strong roses from the open ground now, or even up to the first week in May, if I wanted to gain a season in planting. My out-door roses have been cut about some-

what by the winter, and I am now having them all lifted, rearranged, and replanted, in order to get rid of the cripples, and put a new face on the matter. What I can do anybody else can do; and I will warrant there will be plenty of roses here—that is, for the space they cover—next July, more perhaps than if we had left them untouched. Our reason for doing this job so late is that there has been too much of other work to permit of its being done earlier.

I was amused last week when I opened the Magazine, to find Coupe d'Hébé represented as a dark rose. I soon discovered how it came about. In my hurry, I had forwarded to the printer the wrong woodcut, the same, in fact, as was employed to illustrate Mr. Clarke's paper, published on the 8th of December, 1866 (page 546), and which represents General Jacqueminot, as we did it with the plunge-bed out of doors. I now beg pardon, and present Coupe d'Hébé, in its proper shape and colour, as a model for all ambitious rosarians.

S. H.

Pot Rose Coupe d'Hébé.

THE Rev. Henry Ward Beecher, describing his now organ, says: "The swell died away in delicious suffocation like one singing a sweet song under the bed-clothes."

PET BEDS FOR LADY FLORISTS.

The following short list of useful flower-seeds for bedding are given with a view to assist the fair readers of these pages in attaining an object we know they often desire—that of filling a few beds with flowers of their own raising. For want of knowing what to choose to make a lasting display for the season, and how to grow them when chosen, they frequently give up in despair a task that might be full of delights. Many ladies have perhaps tried and succeeded in so far as to secure from the ordinary list of annuals a few weeks' run of flowers, but at the expense of seeing their beds nearly if not quite empty by the time the ordinary bedding plants are at their best. But such is the fate of many of our most popular annuals when sown, as most people are anxious to sow them, early in the season. Mind, this is not depreciating annuals; I am only reflecting how inexperienced people take them up and are disappointed with the result. The fine flattering descriptions we too often read in the announcements of the seed trade, which the unwary are not always prepared to look upon with the same amount of caution as the old practitioners, lead many astray, and the result is injury to horticulture. But now to my subject with all speed, and I shall choose first the

CALABRIAN SOAPWORT (*Saponaria Calabria*).—A better thing than this we have not in the whole list of annuals, it being easy to raise, not at all particular as to soil or position, and, above all, one of the most abundant flowering plants known, as it will last in full bloom far on into the autumn. When grown in a circular or oval bed with the centre somewhat raised, it has a very pretty effect. I say pretty advisedly, because it is never gaudy, but throughout the season it continues to present a complete mass of flower. Its growth and habit, too, are so regular, so free from all ugliness, that I cannot say too much in its favour. It may be sown at once in the open ground, in a deep pulverised soil that has been well exposed to the weather during winter. The seeds should not be covered more than half an inch deep, and sown pretty thickly, removing some of the plants if they come up too thickly. At the same time a little seed should be sown in some six-inch pots and carefully attended to. These will come in useful should the seeds in the bed come up irregularly, as they may be used to fill up any gaps that occur; or the seed in the first instance may be sown in pots and planted out, the same as ordinary bedding plants. But for myself, I give the preference to plants raised in the open ground. It is not a gross-feeding subject, therefore does not need strong stimulants, but it is greatly benefited by a few good soakings of water in dry weather, which should be given from a fine rose.

SCARLET FLAX.—The next subject, and amenable to the same course of management, is the *Linum grandiflorum*. This is another continuous-flowering annual. It will grow and flower vigorously in a rich deep bed of soil, and is eminently adapted for lady cultivators, as the growth of the plant has a kind of refinement about it such as is generally admired by all our fair readers. There are three kinds—a blue, a white, and a scarlet. The last-named is the one I recommend. I have succeeded best with it when I used to sow about three seeds in some fine light earth in thumb pots. I have placed them in a cold frame early in April, and planted them out in May. But at the place I grew it our position was low, and consequently our soil was damp and cold in the early spring. In warm dry soils, I see no reason why the seeds should not be sown in the open ground, using the same precautions as to securing a few plants in pots, to fill up any gaps that may occur, as advised in the case above.

PURLANE.—I shall next name an old but too much neglected favourite—the *Portulaccas*. The constant accessions to the number of our bedding-out plants have quite driven these out of the field, but I trust this notice may induce some of our readers to bestow upon them a share of their favour, as they are deserving subjects. It is true they are somewhat more troublesome to raise than the hardy annuals, but their beauty more than repays for any amount of trouble they may take to bring them into use; and, as compared to the little extra trouble, the beauty of these plants is an important consideration. Indeed, I cannot imagine anything half so chaste and beautiful in the whole list of annuals, being quite distinct from any commonly grown; and their neat habit of growth, and the chaste markings of the flowers, render them most fit of all to be favourites with the ladies. But to grow them satisfactorily they must have special treatment. In the first place, I may say, that if it is desirable to have a perfect bed, the seed should be had in separate colours. Messrs. Carter and Co. of Holborn used to supply me with a collection of twelve different colours, out of which I could select at the time of flowering eight sufficiently distinct to warrant their being separated, but the remaining four differed so little from the others, that a casual observer could hardly assign to them any peculiar distinctness. That, however, is of but little consequence when compared to the advantage of knowing that you can depend upon the majority coming true to the colours given, as when planting you can the better balance the colours, by arranging the most distinct at such distances as will secure an even distribution

of the most prominent tints over the bed, and by filling in the doubtful ones between, all risk of there being a predominance of any colour over one part of the bed will be avoided. For those who might not care to take the trouble to raise them in separate colours, a shilling packet of mixed seed will be sure to repay the cultivator for all the pains he may take with them. In preparing the pots or pans in which to sow the seed, let them first be thoroughly cleansed and dried, and then half filled with broken potsherds for drainage. Next pound into dust some old mortar, and some old bricks into small nodules, about half the size of hazel-nuts. Take equal quantities of these pounded bricks, silver-sand, and dry leaf-soil. Fill the pots to within an inch of the rims with this mixture, and give it a gentle soaking of water. When this is drained away, sow the seed (which is very fine) thinly on the surface, and cover with a very little dry silver-sand. If the pots are placed on a warm shelf in the greenhouse, and carefully shaded, they will not require any water until the young plants are showing themselves; or they may be raised in a warm room with a southern window. But here they may require water once or twice before the seed germinates, as the air of a room is usually more drying than that of a plant-house; and the water must be given with a very fine rose. From the first to the middle of April is a good time to sow the seed. It will be important to remember that water is the greatest enemy of these plants; but from the time you can detect the first appearance of the seeds germinating, you cannot give them too much heat, as they delight in a dry heated atmosphere, and thrive best when they have but little water and an unbroken continuance of brilliant sunshine. When the plants are well up, in very bright weather give them water twice a week, not more; and not through a rose now, but lay a small convex potsherd just over the rim of the pot, upon this pour the water gently from the spout of a small water-can, and by tilting the pot or pan gently on one side, the water will distribute itself over the whole surface without damping the succulent leaves of the young plants. When I used to grow them, I never pricked them off from the seed-pans; I rather prefer to sow the seed thinly, and grow them on in these pots until the first week in June, when they may be bedded out. Now for the bed; and on the proper construction of this depends in a great measure the success of the cultivator. In the first place, take away all the soil in the bed twelve inches deep, and place in the bottom six inches of brick-bats or flints; upon this put another six inches of the same mixture as advised above for sowing the seed in, but this need not be broken up so fine; into this prick out the plants three inches apart, give a little water, and shade for a couple of days if the weather is very bright, and then leave them to fate. If the summer should be a favourable one, then the result will be a brilliant bed of colours that cannot be surpassed if the whole range of annuals were grown and shown by the side of them. In an ordinary summer they will produce an effect that will surprise many who have never grown them. If we could foretell what the coming summer was going to be, and that it would be a bright sunny one, we might dispense with the drainage beneath the plants, and use the mixture only; but in the absence of any foreknowledge, those who intend to grow them had best adopt the precaution of using it, as a thorough system of drainage is at all times essential to success.

THE GALLARDIA.—*Gallardia picta* is another subject that gives a variety and change of colour, and continues to flower throughout the season. Sown now in a warm place and nursed along, they may be planted out towards the end of May.

JAPAN PINK.—This is the *Dianthus Heddwigi*, of which there are double and single varieties, all of them most charming things to keep up a lasting display. They should be sown in heat, if possible, at once, and planted out in May.

EVERLASTINGS.—For a tall noble subject that will give flowers from July onwards, we have the *Helichrysums*, or everlasting flowers. They make a grand display if planted in deep rich soil, to say nothing of the handsome bouquets they make for in-door decoration during winter.

The above short list contains some of the best of annuals adapted for bedding; but I have not yet exhausted the list, which I may return to some other time.

J. C. CLARKE.

SELECT LIST OF ANNUALS, WITH NOTES ON THEIR CULTURE, &c.

For several years past the demand for greenhouse bedding plants has been on the increase, and the cultivation of annuals has been on the decline. There are at the present time but few gardens in which there is any attempt at the culture of a general collection as formerly, although seedsmen's catalogues enumerate endless varieties. Yet I will venture to say of the many there described but a very few are now inquired after. This is to be regretted to some extent, because among them are to be found some real gems of the floral world. As regards showy and striking colours, they are not to be surpassed by the majority of our bedding plants, so that I do not think it is wise to entirely banish them from our gardens. Then comes the question as to the selection of the best, so that we may ensure a few out of the many that partake of the most useful properties

for all purposes; and as we consider they are indispensable in all well-cultivated gardens, we will, without attempting to classify them, speak of a few, as our memory aids us, with descriptive notes.

SWEET PEAS.—Instead of first sowing these in pots, and afterwards transplanting them into the borders, we would advise the drawing of a drill of some length in a convenient part of the kitchen garden that is easy of access without disturbing the general crops. They would make a very good screen as they grow, if needed. They are very valuable for cut flowers on account of their fragrance. If the soil is very rich, give them taller sticks than usual; always take care they are well supported when growing, for if their tops are allowed to hang over by reason of their weight, it will shorten the duration of their flowering season.

VIRGINIA STOCK.—Common as this annual is, it is yet very beautiful, although it does not last long in flower; still it is to be prized on account of its early blooming. If sown as an edging round a bed, or in a line as a border, it has a very pretty effect. When past flowering, it can be removed to make way for the growth of other plants that will flower the same summer.

CALLIOPSIS.—For a mixed border nothing is more desirable, as they continue to flower more or less during the season, and are very showy, being rich in colour. All the varieties are good.

LUPINS.—A few years since these were favourite flowers in almost every cultivated garden; but now you may range through many grounds in the kingdom before you will obtain a sight of one of them. *L. Cruikshankii* has a very noble appearance; it grows tall, and throws up splendid spikes of flowers. It is well adapted for planting in the back rows of a mixed border. *L. Nanus* is a very neat dwarf plant, and blooms in profusion; it forms a pretty edging, or an excellent bed if needed.

CONVOLVULUS MINOR.—Where there is space sufficient to sow patches in the border, nothing can possibly exceed the grand display these make on a fine summer morning, producing as they do large quantities of rich blue and purple coloured blooms. Always thin them, leaving from three to five plants in a patch, and if possible plant them on the north side of a window, as they turn their faces always to the south, and will therefore be seen from the window with advantage.

MALOPE GRANDIFLORA.—Very showy and free flowerer; in every way suitable for sowing in patches in the back row of a border.

ERYSIMUM PEROFFSKIANUM.—There are very few plants that can boast of so decided an orange colour as this annual. This makes it the more attractive. Growing in patches in the border, it has a very pleasing effect, as it continues in flower for some months.

NEMOPHILA INSIGNIS.—This well-known annual requires no comment from my pen in its favour, as it is already an established favourite; but it is not generally understood that it will make a very showy and effective bed early in the spring. My plan is to sow it in drills in November, affording sufficient width to plant bedding plants betwixt when it is in flower in May. To ensure strong plants and good blooms, bestow some care on the thinning of the rows or patches.

SAPONARIA CALABRICA.—There is something very interesting and dazzling as you gaze on this striking annual when in full bloom; it literally appears to clothe the surface of the earth on which it is growing with a countless multitude of starry pink coloured flowers. It continues a long time in bloom, and forms a very neat edging if used as such. It is seen to great advantage when growing on a slope or bank.

I could extend this list threefold; but my object is to create a taste for the cultivation of those that are really desirable. JOHN F. McELROY.

CANDLEMAS DAY AND THE SUBSEQUENT WEATHER.

Some time ago Sir J. Herschel recommended persons who attend to the "signs of the weather," and put faith in any particular weather-adage often repeated, to keep a note-book and set down, without bias, all the instances in confirmation or in contradiction of the same; and he added that he would be very glad to enlarge his own experience by the obliging communication of such memoranda (*Good Words*, January, 1864). One of these popular maxims has had a remarkable fulfilment in the present return of winter.

Sir Thomas Browne, in his *Vulgar Errors*, quotes a Latin couplet as follows:—

Si Sol splendescat Maria Purificante,
Major erit glacies post festum quam fuit antè.

That is, "Should the sun shine out at the purification or churching of the Virgin Mary, there will be more ice after the festival than there was before it."

The adage is thus paraphrased in the popular Scottish rhyme:—

If Candlemas-day be dry and fair,
The half o' winter is to come and mair;
If Candlemas-day be wet and foul,
The half o' winter's gane at Yule.

Now last Candlemas-day (February 2nd) was a remarkably fine day in London, and, as far as I can ascertain, much about the same throughout the country. I noted it at the time with the view of verification.

In Germany there are two proverbial expressions on this subject: 1. The shepherd would rather see the wolf enter his stable on Candlemas-day than the sun. 2. The badger peeps out of his hole on Candlemas-day, and, when he finds snow, walks abroad; but if he sees the sun shining he draws back into his hole.

It has been deemed not improbable that these notions—like the festival of Candlemas itself—are derived from pagan times, and have existed since the infancy of our race.

Forster, a very patient and accurate observer, states that he has "noticed this to be a critical time of the year with respect to the weather," and that, when mild and wet, winter is actually gone, and we may calculate on no more frost, quoting another version of the proverb:—

If Candlemas-day be fair and bright,
Winter will have another flight;
But if Candlemas-day bring clouds and rain,
Winter is gone and will not come again.

Probably Candlemas-day was only the prominent day selected to fix the characteristic of the period, extending back to the 23rd of January, by which time the utmost rigour of frost is usually expended, followed by westerly gales, "mild and wet"—in countries where the seasons are more regular than in England. Fine and frosty weather at the period would therefore indicate a continuance of wintry weather. A. S.

Calendar.

WORK FOR WEEK COMMENCING APRIL 6.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—Successional sowing may be made of all leading kitchen crops, and where the work of the last month has been delayed, seeds got in early will not be much behind those sown last month. Sowings should also be made of Horn carrot, Savoy, Brussels sprouts, Scotch kale, broccoli, cauliflowers, and cabbages, for autumn use; a succession of such things being preferable to a glut all at once for the private grower. The main crop of cabbages should be up by this time, and must be hoed between when the ground is in a fit state. Beet should be sown this week or next, in ground deeply dug, but not manured; the main crop of celery should be sown on a rich warm border, the surface to be made light and fine; sow thin, and merely dust the seed over. Sow also onions, lettuce, radish, small salad, seakale, and asparagus; the two last in drills, one foot apart, and one inch deep for asparagus, and two inches for seakale. Another mode of raising seakale plants is to sow in four-foot beds, the seed to be in patches of eight inches in diameter, and two feet apart, and about eight seeds in each, the plants to be thinned to three plants in each patch; the ground should be rich, well drained, and deep. Beds may also be formed now by planting roots, but the best plantations are those raised on the spot from seeds. Those who purpose raising seedling rhubarb plants should sow about the middle of the month in shallow drills, eighteen inches apart, dropping the seeds in patches six inches from each other. Potatoes not yet planted should be got in without delay, and towards the end of the month scarlet runners and French beans may be sown; the runners should have a warm dry position until the 1st of May, when they may be sown in almost any soil or situation without risk, but, like most other things, yield the best crops on ground well dug and manured. The main crop of carrots should be got in about the fifteenth of the month, and there is still time for a crop of parsnips, but they must be sown directly. Slips of kitchen herbs may be put in any time this month, and will root quicker if planted in a rather dry sandy border.

CELERY.—Sow for the last time, in seed-pans, and place on a hotbed; but if no convenience of that kind, sow on a warm dry border, and it will come up in time to make good plants for a late supply. When there are no conveniences for growing celery in trenches, useful plants may be had for soup by sowing any of the red kinds on a warm border, and when large enough, planting them out in beds, six inches apart every way. These need not be earthed up at all, as the earthing is intended to blanch it, and for soup that is not necessary. This plan is recommended for poor shallow soils where fine heads of celery for table cannot be produced. Prick out, on a bed of three parts rotten dung and one part loam, the plants from the last sowing; and pot off singly, in 60-sized pots, the plants for the first crop, which encourage with a moist heat in a cucumber pit. We always turn out from the pots our first crop of celery, and obtain fine heads early in the season; it is a method which occasions no check to the plants.

ONIONS for salads to be sown frequently. Fork over the beds of main crop, and if no blade appearing, or if the blade is thin, make up your mind whether you ought to sow again. Onions sown last autumn may now be transplanted to rich beds, in rows nine inches apart, and be helped with occasional sprinklings of guano on the surface.

POTATOES.—It is not too late now to get in the main crop, but it had best not be longer delayed.

TOMATOES, CAPSICUMS, &c.—Pot off as fast as needful, and keep them growing vigorously. It is not too late to sow if they have been neglected.

VEGETABLE MARROW sown now will produce almost as early as those sown a fortnight or a month since. It is best to get the plants on singly in pots, as they are shorter and stronger when turned out than if grown several in a pot and allowed to sprawl about and spindle away their strength.

OUTDOOR WORK.—The month of April is one which generally tests severely the cultural capabilities of the gardener, as well as his ways and means. The weather may be summer one day and winter the next; and inexperienced hands may easily be led astray by the temptations of warm showers and sunshine to regret afterwards the havoc caused by sudden frosts, storms, and even snow and hail. In the general work of the garden, many of the directions—especially as to sowing—given last month apply to this, and more particularly to those who live in exposed districts. Those who live far south, in the almost Italian climate of Devonshire, will often have things up at the time we are instructing them to sow; while residents on the bleak Northumberland coast, or in the eastern parts of Scotland, will always be a fortnight, sometimes a month, behind us.

KIDNEY BEANS.—Sow a small lot of Newington Wonder or Fulmer's forcing beans on a warm border at once, and in ten days make another sowing. Sow Negro or Speckled Dun the third week, and runners the last week of the month.

BEANS to be dressed with soot or wood ashes, and hoed up quite to the lowest leaves. Sow for succession; they like a rich retentive soil.

CUCUMBERS.—Sow for ridging out, and get the plants forward in pots. They turn out better when singly, in 60 or 48 pots; they should have no check. Shift those already forward. Splash water about the beds of fruiting plants, and close early, so as to give the plants a good steaming, which they will enjoy.

Flower Garden.

FLOWER GARDEN.—Seeds of hardy annuals and perennials are to be sown early, and towards the end of the month the more tender kinds may be safely committed to the ground; but very small seeds of choice things had better not be sown till next month, as heavy rains may wash them down into the soil, and they may be lost. Perennials may be planted out, and old stools of Phlox, Chrysanthemum, Sweet William, &c., may be parted. Dahlia roots may also be planted, and if the shoots appear before night frosts are over, they may be protected by flower-pots inverted over them, the holes stopped with tile. Box edgings should be clipped, and ivy may be out-in and trimmed, and fresh plantations made of last year's roots. Cuttings of ivy may also be taken and planted in a sandy border, only partially exposed to the sun. The cuttings should be short-jointed and trimmed of the lower leaves. Tigrida bulbs may be planted two inches deep. A light netting or some similar protection will be found useful now as a protection to tulip beds, and if the foliage gets frozen, water them with cold water before the sun gets on them. Walks

should be turned and rolled, and grass-plots dressed, so as to give an air of neatness and order to the whole of the ground.

LAWNS to be mown and rolled, and daisies spudded out before they scatter their seeds. Our grass has been once mown already.

PANSIES.—This is a good time to buy in stock of new kinds, and to sow for pot and border bloom. Cuttings of bedding kinds put in now will make nice plants to bloom all the summer; better than if propagated earlier.

ANNUALS of all kinds may be sown now in the open air; the hardy sorts will be up in from ten days to three weeks, and tender kinds in a month or six weeks. It is often a convenience to sow all kinds at once, in accordance with a general plan, and it may be done in April. Of course, Asters, Balsams, &c., rarely come to much good by this offhand method.

AURICULAS to be shaded as the bloom progresses, and have shelter at night by means of mats. Give plenty of water and plenty of air. Thin the pips in good time to the standard number, whatever that may be.

CHRYSANTHEMUMS for general purposes to be now propagated. Suckers are as good as cuttings; and there need be no disputes about the relative values. They do not require much heat to start them, and nothing better than a gentle hotbed on the old-fashioned plan. Old stools may be planted out in the borders.

HOLLYHOCKS planted now from store pots will bloom to perfection, and have no check from frost. Put a couple of spadefuls of rotten dung in each hole, plant firm, tally and stake at once; cover each plant with an inverted flower-pot for a week, and then remove it. Give plenty of water and liquid manure as required.

HYACINTHS must have abundance of water while in bloom, and for some time after; as long, indeed, as the foliage continues green and growing. After it begins to get discoloured, dry them off gradually, and lay the pots on their sides, where they will have morning and evening sun to ripen the bulbs.

VIOLETS planted now from young runners of Russian and the double-flowering kinds will make fine plants. Seedling plants generally bloom most profusely, and in most of the seed catalogues the best kinds are entered.

Greenhouse and Conservatory.

GREENHOUSE AND PIT.—If bedding stock is still in request, cuttings should be struck in a brisk heat, even as high as 90°; they will bear much more heat now than they would a month ago. China roses may be propagated in pots by taking off young shoots close to the old wood when four inches long, and plunging in a moderate heat. General collections should only have a moderate heat, and a strong healthy growth should be promoted by giving plenty of air, with a view to putting out the fires for the season. Many specimen plants will want liberal shifts, and all subjects not immediately required in flower should be regularly and frequently stopped, to induce bushy growth and form good heads. Water and liquid manure must be more freely given, and vigilant efforts must be made to keep down green-fly and thrips. Many of the less tender things may be removed to cold pits, to increase the room for other things that want continued protection to make fine plants. Young stuff from the propagating house should be potted as fast as rooted, and kept close till started afresh, and then be gradually inured in air and light, so as to be strong by the middle of May. All tropical plants required for summer blooming in the house should be got on without delay, and a quick growth promoted, so as to allow them as long a season as possible for blooming, and ripening their buds for next season. Where desirable, the house may be shut up with sun-heat to render fire unnecessary.

AZALEAS done flowering must be kept rather close, and in a moist atmosphere to favour a quick growth, as it is important to get the new wood well ripened when the growth is completed. Those that are cramped at the roots must be repotted in good peat and silky loam. Artificial peat is wholly unfit for such plants in pots.

CALCEOLARIAS coming into bloom must have plenty of water and free ventilation. Syringe the lower leaves and branches, but wet the blossoms as little as possible.

CAMELLIAS done blooming treat the same as advised for azaleas. Those coming into bloom must have occasional strengthening with liquid manure. Lanky plants will be improved by removing the top buds before they expand, to throw vigour into the lower branches.

BEDDING PLANTS.—If our advices have been followed, most of these are now in a forward state, and their pots full of roots. Shift any that are wanted large for centres of beds and back rows of ribbons. Now proceed to propagate variegated Geraniums and silver-leaved plants, which, as bloom is not of much consequence, need not be got on so early as the flowering kinds. *Cersium tomentosum*, cut up into bits two inches long, the lower leaves of the cuttings removed, and dibbled into pans of very sandy soil, will be in prime condition for planting at bedding-out time. It may be delayed another week if work presses hard. The same with variegated Mint—much better when struck late in spring from shoots truly coloured than if got forward too early. The variegated Arabis may be rooted quickly in the same way by dividing it into separate crowns. It is said to be shy of rooting now that it is in flower, but that is a mistake, as we know from having raised millions of plants at this time of year. If there is a moderate quantity of old stools, they may be divided and planted in tufts, with a bit of root to each, four inches apart, at the end of this month, and will meet and form a lovely yellowish-grey line by the middle of June. Verbenas and Petunias struck now will make good bedding plants, if encouraged to grow after potted off. This is the best time also to put in cuttings of bedding Tropæolums, which flower best and grow more moderately when struck late and planted out in poor soil.

CINERARIAS are very fine this season, and some good seedlings have made their appearance. It is a good time for beginners to purchase sorts in bloom to propagate for stock. Green-fly will annoy the plants, unless kept down with gentle smokings. Dung, three parts rotten, and mellow hazel-loam should be chopped over and laid up at once for potting the next lot, so as to be sweet and friable when wanted.

CONSERVATORY should now be very gay with hedges, csmellias, and forced deciduous shrubs and trees. Look out at once for the summer supply. Cannas are now fashionable for their fine tropical-looking foliage, and some new varieties of Ricinus will be much used to help the foliage effects of Caladiums, &c. *Datura Wrightii* is a charming convolvulus-like herbaceous plant for a warm house, and delightfully scented. Sow seed now in a brisk heat. Treat the same as balsam. We have some plants that have

flowered five years in succession, and have now large fleshy roots; it is therefore a mistake to call it an annual.

DAHLIAS for show ought now to be strong in 60 pots, and kept growing slowly. Cuttings put in now will make good plants. For large specimens, use old plants, to be started now at the bottom of a vinery or a cool part of a pine-pit.

PELAROONUMS to be encouraged to grow freely by the use of the syringe and regular tying out. Fumigate as soon as fly appears, or much mischief may ensue. Plants showing for bloom to have weak manure or soot-water at every other watering.

Fruit Garden and Orchard House.

WALL AND BUSH FRUITS should be hunted over now, to gather the first crop of young caterpillars. There is no process like hand-picking, and where to pick will be known by the curl of the leaves. Trees that were washed in winter, as we recommended, will probably be very clean in their first growth. Disbud and thin fruit with judgment, and remember that there is nothing gained in the end by taking too large a crop from a fruitful tree. In disbudding, do not remove too many buds at a time. First take off with finger and thumb those that are obviously ill-placed; a week afterwards select a few for laying in to keep up the furniture with young wood, and remove others that are again evidently not needed. This process will very much reduce the work of summer pruning, and strengthen the shoots left to form bearing wood. It makes one shudder to see how some gardeners lay in all the wood they can get, till their walls are literally felted, as if peaches and apricots were to serve the same purpose as ivy. Be in no haste to remove tiffany and other shelters from walls; but let the trees have air; they are as fond of it as you are.

ORCHARD HOUSE.—If this is crammed full of all sorts of things in pots, which is too often the case at this time of year, make a general clearance, for this system of making too much of the glass leads to mismanagement, and one common result is keeping the trees too close in order to help more delicate subjects. *Trees must have air*, and plenty of it. Let the wind whistle among the bloom, and it will set freely. Give plenty of water at the roots of the trees.

Stove and Orchid House.

ORCHID HOUSE.—An increase of heat and moisture will now be required for orchids of all kinds, in both Indian and Mexican houses, but water must not be applied directly to any until growth has fairly commenced. Specimens of *Cattleya*, *Calanthe*, *Phajus*, *Saccolabium*, *Stanhopea*, *Zygopetalum*, *Brassia*, *Dendrobium*, and *Sobralia* will require frequently syringing about their pots and blocks as the plants advance; in fact, the cultivator must now encourage luxuriant growth as early as possible, in order to get the bulbs well ripened in the autumn. Shading must be put up not later than the second week of the month, but a better plan is to have good roller blinds, so as to shade at will, if only for an hour or two, when there is a hot sun with an east wind. Growers of *Anæctochilus* usually place them on bottom-heat, and keep very close at this time of year, which is the very opposite of good practice. Bottom-heat causes too quick a growth, which results in weakness, and want of ventilation adds to mischief, and the two evils are frequently combined for the destruction of collections for which large sums of money have been paid. Ordinary stove temperature is all they require. Let the bell-glasses be always slightly tilted up; this will render necessary more frequent watering at the root, which the plants will enjoy from the present time to the end of September. Any not newly repotted this season should be repotted without delay, in a mixture of equal parts of sphagnum, chopped fine, and fibry peat with one-half part of sharp silver-sand. In potting, raise the collar a little above the soil and finish with a slight sprinkling of washed silver-sand on the surface.

Forcing &c.

FORCING must be continued with lettuce, mint, asparagus, and potatoes. Many of the complaints of failure which reach us are attributable to high night temperatures. All sources of heat that are under full control, such as hot water and flues, admit of being reduced or increased as required, and the temperature should always fall from five to ten degrees at night in hested structures of all kinds.

DANDELION, grown in Pascal's seakale-pots in a gentle dung-heat, forms an elegant and acceptable salad. Strong plants may be forced the same as seakale and asparagus, and must be thoroughly blanched, to prevent bitterness. Any old plants in places about the garden may be blanched where they are by turning a pot over them, and stopping the hole with a piece of tile.

PINES will want shade on bright days, and sir as often as possible, but the atmosphere about them must be kept moist, and the roots well soaked whenever the soil about them is dry. Red spider will now be getting active, and must be kept down. Keep also a good look-out for green fly, especially among young stock. Average temperature for pines, 70° by night, 80° by day.

PERIODICALS.

The Floral World for April contains a paper in continuation of the editor's remarks on Collecting and Selecting, the title of which is "The Arcanum of Perpetual Beauty." In this he gives an account of the method by which certain portions of the garden may be kept in a state of high embellishment all the year round, constantly changing in aspect, yet never deficient of beautiful combinations and interesting objects. Amongst the other portions of the bill of fare are articles on the Auricula, by Mr. Walsh; on plants of grand character for English gardens, by Mr. Proser; a selection of Herbaceous Plants, by The O'Shane; a list of the best varieties of *Polystichum angulare*, by the editor; a paper on the Cineraria, by Mr. Turner, from the "Gardener's Annual;" and the usual notes on New Plants, news of the month, &c.

The Intellectual Observer for April contains a most entertaining paper by Mr. Henry Woodward, of the British Museum, on shells and their inhabitants; a valuable contribution to experimental science, by Professor A. H. Church, on "Chemical aids to art;" a readable account of the natural history aspects of some parts of Shropshire, by the Rev. J. D. La Touche; and various contributions by Mr. H. J. Slack, Rev. T. W. Webb, Rev. W. Houghton, and Mr. N. T. Lynn.

Our Own Fireside for April is a good number. Mrs. Ellis continues to contribute, and Mrs. Beecher Stowe appears with an essay on "Fault-finding." In the scientific department are some interesting particulars of Esquimaux life, and a pretty batch of anecdotes of animals.

Correspondence.

EMIGRATION FOR GARDENERS.—I should feel greatly obliged if you or any of your correspondents could furnish me with some information as to the spirit of horticulture carried on in the United States of America, and in what part would be a likely place to get employment in our line, as I am desirous of emigrating to that prosperous country, and also of getting on in my occupation as far as my abilities will allow. I should be grateful for a word of advice through the pages of your GARDENER'S MAGAZINE.

A YOUNG GARDENER.

Replies to Queries.

Double Petunias.—J. and T. T.—The double varieties yield but small supplies of seed, and those are obtained from semi-double flowers. The flowers that are thoroughly double do not produce seed at all. To raise double varieties from seed requires only ordinary good culture, but the result is all a chance. Those who give their attention to the raising of such things grow thousands, and as fast as they flower they destroy them, unless they possess some superior qualities. It is true, an amateur growing a dozen or two might happen to obtain out of them a few extra fine varieties, but such luck is not to be expected. These things follow a law of their own.

Vines.—Polly.—It is not well to apply nostrums to the tender leaves of vines. What you take to be the eggs of insects are probably such warts as are commonly met with on vines that are in too warm and too moist an atmosphere. It is not good for vines to be thus affected, and we therefore advise more ventilation and less moisture. The other subject shortly.

Various Queries.—Scientific Amateur.—We do not know the "cherrycluck" set up in gardens for the purpose of keeping birds off fruit-trees. It must be some sort of miniature windmill. Perhaps Messrs. Bury and Pollard can give you some information on the subject. Messrs. Negretti and Zambra can probably supply the new Anemometer figured by M. Craveri in the Archives des Sciences of Geneva. *Hernandia sonora* has been registered as a plant in cultivation in this country for nearly two hundred years, but you might search far and wide to obtain it. Try Messrs. Veitch, Mr. Bull, and Mr. B. S. Williams. In Herschell's "Outlines of Astronomy" is the best account of the harvest moon that we can call to mind at this moment. There are some excellent maps of the stars in the Atlas published by the Society for the Diffusion of Useful Knowledge. These you might hear of by applying to Mr. Stanford, Charing Cross.

Bowood Muscat.—New Subscriber.—This grape requires a good heat to ripen it, as much in fact as any muscat. As your vines commonly produce plenty of promising bunches, yet fail to ripen them, we suspect there is a want of reciprocity between the roots and the branches. What to advise we do not know, because you furnish no particulars of the house or the border in which these vines are situated. But we have the right to guess that the roots are in a fat cold border, that they are neither dry enough nor warm enough, and that they consist chiefly of strong, fat, far-reaching, rope-like roots, instead of surface fibres close home. Our view of the case may lead you to discover for yourself the remedy for the evil of which you complain. The probability is that these vines will never do any good till they are lifted and replanted in a warm, comparatively dry, and not over rich border. For the present we advise you not to use liquid manure this season at all, and to give only as much water as is absolutely necessary to keep the vines going. For some time to come practise upon these vines as the Frenchman did upon his horse, but stop in time to avoid the Frenchman's disaster.

Messrs. Alexander.—We cannot spare time to test your chemical manure; if you wish to give it publicity, your best course is to advertise it.

A. B. C.—Your plant is the lovely African lily, *Agapanthus umbellatus*.

Orange-coloured Annual.—Commelina asks if we can recommend a dwarf annual of any effective shade, either of yellow or orange, that may be sown in autumn to flower the succeeding spring, along with *Silene pendula*, *Saponaria*, &c. Would *Leptosiphon aurea* be hardy enough? There is a yellow and white *Nemophila* which would do, yet I do not know its botanical name. Yes, *Erysimum Arkansanum*, which is like a golden phlox, will do precisely what you want. Probably *E. Peroffskianum* might also be useful, but we should prefer to trust to the first. A dwarf double wall-flower would be an acquisition for this sort of work, but we do not know of one that we can recommend off-hand.

Wood-lice.—J. H. P.—There is no mystery at all about getting rid of wood-lice; it is a matter of skill first and perseverance afterwards. The skill is a small matter; the perseverance almost everything. Wood-lice are fond of any juicy vegetables of a wholesome kind, and they love to lurk in dry dark places. It is therefore a most easy matter to trap them, and having trapped them, to destroy them. Your cucumbers are destroyed by them. Well, cut a cucumber, and humour their tastes by putting slices of it on some tufts of dry moss, which cover with clean pots or pans, or even with lids of baskets or pieces of board. If you cannot afford to give them a cucumber, use slices of apple or potato. If you have plenty of young lettuce-plants in frames, use the outside leaves as bait. Whatever is dry and dark will make a trap. Perhaps the simplest traps are small flower-pots, with a bait put in and covered very lightly with dry moss or shavings. Very soon the wood-lice will find out the treat and will nestle in the traps, and if they are examined daily (by daylight) the vermin may be quickly swept out of the traps into boiling water, and the place may be cleared of them in a week or two.

Varieties of Apples.—Centurion.—*Monstreuse d'Amérique* is a large, roundish, flattened apple of fine quality for kitchen use. The tree is a strong grower, and bears well. *Duchess of Brabant* we know nothing of. *Reinette Royale* we believe to be identical with *Reinette du Canada*, a fine large yellow apple with light red cheek; good for both kitchen and dessert. *Yellow Newtown* is a medium-sized conical apple, of a lemon yellow colour, good for both table and kitchen. *Newtown Nonpareil* we do not know; probably identical with *Newtown Pippin*. *Calville Rouge* is pretty well known as *Winter Red Calville*, a large oblong fruit, pale red with deep red cheek; a good culinary apple. *Calville Rouge d'Hiver* is the same as the last.

Ne quid nimis.—We make it a rule not to propose plans for the planting of beds, for the very good reason that we could not hope to please people, and could not bestow the time requisite to consider all the cases that would be submitted.

Book on Investments, &c.—Orion.—"Playford on Investing," published by Virtue Brothers, will probably suit you. Pray do not write again to ask the price; we do not know it. If you write to anybody, write to Messrs. Virtue.

Plant Labels.—Early Sub.—We do not know where to obtain the label you inquire about. You will find, on reference to "The Floral World," that we have written one very class of ferns almost every month for ten years past. As for the label business, it is all in a fog; the best labels at present are those made at home.

Gladioli.—M. D. S.—Sea-sand will do for gladioli if previously exposed for some time to the weather, or well washed to remove the salt. We have known sea-sand to be largely used in growing hyacinths without any washing—in fact, quite fresh from the beach, and the bulbs did well, in fact, extra well. It might be so with gladioli. Try it with a few bulbs, and let us know the result. But do not risk any that are valuable in any sea-sand until it is washed, when it will be quite safe and suitable. We are strongly of opinion that the washing is unnecessary, but cannot from experience recommend the use of unwashed sea-sand.

Heating Small Greenhouse.—H. F.—A small conical boiler, and pipes of two or three inches diameter, would produce the kind of heat you want. The boiler would have to be outside, and coke would be the proper fuel. The fact is, these small houses cannot be heated satisfactorily; and when correspondents expect us to settle the matter in a word like magic, they expect an impossibility. Nor can we advise you about the height and pitch of your house; why, you do not give the measure, or even say in what sort of position it is to be in. Now suppose yourself an architect, and a man writes to say he intends to build himself a residence, and wishes to know if it should be Gothic or Tudor, or Italian or Chinese, what sort of answer would you give? You would tell him to please himself, and that is the best answer we can give you. If you wish to grow great plants, have the roof high enough for them; if little plants, have it high enough for yourself.

Beds on Lawn.—A. B.—No. 1, large centre of geranium, *Kate Anderson*; broad band of geranium, *Flower of Spring*; edge of blue *Lobelia*. No. 2, *Calceolaria, Aurea floribunda*. No. 3, *Geranium, Christine*. No. 4, *Calceolaria, Bird of Paradise*. No. 5, *Geranium, Minnie*. Nos. 2, 3, 4, 5 to be edged with blue *Lobelia* or *Cerastium tomentosum*.

* * * The Editor can recommend a Gardener who could take charge of the grounds of a public asylum. The principal work would be in the kitchen garden, of which he must be a master. No forcing or fancy work.

FRUIT TREE PROTECTION.

Many, and often conflicting, are the opinions with regard to the necessity or otherwise, the advantages and disadvantages, of protecting wall trees when in blossom. That there is risk in leaving the trees to exposure and chance few, we think, will deny; that the material and mode of protection are often at fault, and a greater cause of injury than the evil they are intended to guard against, must also be admitted. As the season is now upon us, when the matter is uppermost in the minds of horticulturists, a few words on the subject will not be out of place. In the first place, it must be thoroughly understood that any protection that will exclude those important agents—air and light—from the trees will be positively injurious. Therefore, such material as will admit of the freest and least interrupted action of both, and, at the same time, secure a dry atmosphere about the trees must, undoubtedly, be, of all others, the most desirable. If the trees and blossoms be wet, the atmosphere charged with moisture, and a frost suddenly supervene, the bloom will be much more liable to suffer than under opposite conditions. Any one, then, who has old hothouse sashes or unused frame or pit lights to spare, will have the best of all material for protection. They may be got into position at once and fixed, just taking care not to put them close together, and to leave them open at the ends, in order that the circulation of air may be free. When once fixed, all anxiety may be laid aside, and the necessity of attendance to sudden or apprehended change of weather, as well as the trouble entailed and time lost in removing or running up by day and letting down at night, when other modes of protection are adopted, are altogether obviated.

It is not in many places, however, that sashes are available. It may here be a question after all, considering the cheapness of glass, if light, portable glazed frames kept at hand for the purpose, might not be after all the most economical, as they would, doubtless, be the best. They would be available for many other purposes, and among them one which, notwithstanding the stress laid on spring protection, is scarcely less important, though little thought of. We allude to autumn protection, and as aids to ripening the wood, more especially after a wet, cold, unless season, such as we had last year, and too frequently experience. But in the absence of glazed protecting material we must take the next most convenient. The thin flat spray of the spruce is often used, but care must be taken so to place it that a space of three or four inches may be left between it and the trees, and it be placed so as to admit as much light as possible. Canvas, calico, woollen netting, doubled, tiffany, all offer themselves for the purpose. If so adapted that the protecting agent can be run up and down like window blinds, or drawn to either side by rings like a curtain, when required, it will be all the better. We have seen another mode of protecting the bloom practised, and, as we are informed, with the best possible effect. Eschewing the use of protecting materials of any kind, the practice is this: As soon as the blossoms expand they are dredged with fine sulphur from an ordinary dredging-box or the sulphurator, so as to fill the cup of the blossom and cover the reproductive organs within it. The rationale of the success attributed to the practice is not very obvious, but we apprehend it may be found to lie somewhere in the direction of the insolubility in water and non-conducting properties of sulphur. We wish some few of our practical friends would give it a trial by sulphuring one half of a tree and leaving the other untouched; or what would, perhaps, be better, some of the alternate ramifications, marking those dressed with the sulphur and noting the results.

To conclude, one thing is certain, that if we may not err in being prompt in the application of protection at the proper time, we are still less likely to do so in being slow to remove it.—*Irish Farmer's Gazette*.

A MINISTER in Massachusetts lately took occasion to administer a reproof to old Joe for swearing. Joe listened attentively to his words, seemed to appreciate the exhortation, and, when he had concluded, replied as follows: "The fact is, parson, that I may swear a great deal, and you may pray a deal, but neither of us means anything by it."

The Gardener's Magazine.

SATURDAY, APRIL 13, 1867.

FLOWER SHOWS FOR THE POOR continue to multiply and prosper both in the metropolis and in all large and densely populated towns. It is impossible that the movement out of which these exhibitions originated can be otherwise than beneficial, and it is the duty, and should be esteemed the privilege, of all who can assist to lend a helping hand in a spirit of the most disinterested kindness. It does not, however, lie in the province of the horticulturist merely to initiate an exhibition of this sort. It is a social and domestic movement, it is far removed from the ordinary domain of science, and the horticulturist can assist only when the clergy and philanthropists associated with them have made a beginning, and laid the foundation for something tangible. To institute a horticultural competition amongst the dwellers in dark lanes and alleys, who, of all classes needing the refining influences of fresh air and vegetable beauty, are least able to obtain them, may be good in itself; but we can only seriously regard it as part of a scheme having for its object to ameliorate the domestic circumstances of the poor in great towns, by the inculcation of habits of sobriety, cleanliness, and thrift, and the diffusion of those religious and moral truths that bear directly on human welfare. It is in one part of the scheme that the horticulturist, as such, finds himself some work to do. And hitherto horticulturists have been for the most part rather astonished at the tasks allotted them; but it has been evident from the first that, without competent horticultural guidance and authority, these flower-shows must end in grief. In some cases, the promoters of these shows are so ambitious as to attempt an exhibition which shall attract the general public, or such of the public as, for the promotion of a good cause, can be persuaded to pay a fee for admission. Here the possessor of decorative plants comes in usefully, and it is his business, if proposing to assist in earnest, to "make a show." Another part of the practical cultivator's task is to advise about arrangements, and no small burden of responsibility rests upon him for impartial judgment of the competitive contributions. Now we beg, for all the poor people's exhibitions that are to be held this year, the generous consideration of horticulturists in the several districts in which the exhibitions occur. Let them not suppose that the interests of horticulture are in any way bound up with this movement. It is quite otherwise. But much more important interests are concerned—the interests of humanity; and whose loves flowers, loves also, we assume, his fellow-man.

He prayeth best who loveth best
All things, both great and small.

And every religious, moral, and social consideration that may engage the heart and mind of the true philanthropist, has direct relationship to the prosperity of this movement. To relieve distress, to teach the ignorant, to lift up all who are weary and cast down, is the duty, not of a class, but of all who possess the means of help; but the cultivator of plants enjoys the peculiar advantage of being enabled to make sunshine in the poor man's path, and it is with unfeigned pleasure we can say, in reference to this peculiar class of exhibitions, that horticulturists have not hitherto been slack of willingness and sacrifice in their behalf. We have seen men whose labours are commonly severe, in the midst of the busiest part of the exhibition season, devoting themselves generously and earnestly in this cause, and doing for it what none else can do, for at a certain point the philanthropist must step aside and leave the work in the hands of a gardener. The judging is indeed a strange task, for the subjects to be judged are such queer examples of plant growing; yet there is a spirited rivalry, and it needs a competent judge, not only to distinguish as to the merits of *bona fide* competitions, but to disqualify subjects that have no proper claim to compete. That a trick should now and then require to be denounced, should not prejudice the movement as a whole—for tricks are perpetrated at the greatest and grandest of flower-shows; and if these shows are not suppressed because of great sinners, neither should the more humble ones be because of little sinners. But, as a rule, the *bona fides* are well guarded by an essential part of the movement, which consists in visiting the poor at their homes, encouraging them in habits of cleanliness and the observance of religious and moral duties, and providing them with plants to make their rooms cheerful.

No. 102, NEW SERIES.—VOL. X.

The visitors become acquainted with the plants that are intended to be shown, and, generally speaking, every one can be identified when on the exhibition table, and therefore attempts at imposition are of comparatively rare occurrence. But now and then a fresh plant, purchased at Covent-Garden Market, or obtained by gift from a country gardener, finds its way to the show; and if the judge (one is generally sufficient) understands his work, it is picked out and referred to the committee, who proceed to ascertain if it has been in the possession of the exhibitor a sufficient length of time to fulfil the requirements of the schedule. A strict system of judging is one of the vital elements of an exhibition of this sort, not so much in its horticultural as in its moral bearings, and neither judges nor committees should ever wink at any intended wrong, however generous they may be, and must be, in other matters.

It is not at all surprising that a few mistakes should have been made in the machinery for promoting these exhibitions. In some cases subjects are entered in the schedule that are quite beyond the capabilities of the cultivators invited to compete. Usually, the committees consist of persons wholly unacquainted with horticulture, and therefore the mistakes are pardonable; but it would be well if in every case some person skilled in practical matters could be persuaded to take part in the proceedings as a promoter, for mistakes are injurious. The poor are easily discouraged, and when grievously disappointed, there is usually a feeling of suspicion aroused that they have not been fairly dealt with. A very great mistake was made in the autumn of last year in the distribution of the bedding plants taken up in the public parks to ragged schools and mission houses, for distribution amongst the poor. When our contemporaries were eulogising the benevolence of the Government, we had not a word to say, and only when the winter was close at hand did we consent to chronicle the fact, at the special request of certain of our correspondents. We are gratified now that we gave that movement no encouragement, and regret that we did not take an active opposite course, and warn our philanthropic friends to abstain from participating in the spurious boon. Where are all those plants now? Perhaps one in every thousand may be alive; we seriously doubt if the numbers that have survived the winter exceed that supposed proportion. Such a proceeding as an injudicious distribution of plants must tend greatly to check the progress of floriculture amongst the poor, who are sure in time to discover that they have been put under obligation for worthless gifts. A few thousands of thrifty young plants distributed now, amongst the denizens of courts and alleys, would give delight, would stimulate the recipients to careful cultivation of them, would quicken their enjoyment of such few glimpses of awakening nature as they obtain from the open spaces and gardens that are within view as they pass to and fro in the streets. It is a sad thing, however, that in all the central parts of London, where the poor most do congregate, open spaces and visible gardens are few; and wherever they belong to public bodies they are, as a rule, hideous to behold, and a disgrace to all concerned in their keeping. To improve the open spaces in great towns is as necessary a work, on the ground of philanthropy, as the promotion of tidy rooms and little flower shows.

VARIEGATED CONIFERS are frequently presented to public notice at horticultural exhibitions and in other ways; but it is seldom any of them actually take a place amongst cultivated varieties, or are ever met with beyond the boundaries of the garden in which they originated. One great difficulty in the way of their distribution is their propagation; but another difficulty, and, in fact, more than a difficulty, is the fact of the variegation "running out" in the young plants, so that when a stock had been raised, it was found to be, not a new variety, but the original restored. There are a few Thuas and Cupressus in cultivation that are exceptions to the rule; these are not only finely variegated, but pretty constant to their characters as variegated varieties in all stages of their progress, and under many differences of condition as to soil and climate. Mr. J. B. Hartland, of the Lough Nurseries, Cork, has been more than usually fortunate in producing, keeping, and multiplying variegated coniferous trees, and we have before us some specimens that give more than an average promise of making decided and delightful effects in gardens and plantations. One of these trees is a variegated *Wellingtonia gigantea*, the garden name of which is *Aurea variegata*. The original tree is about 12 feet high, and has a circumference of over 30 feet; in its proportions and outlines it is a true *Wellingtonia*, which is saying enough in respect of its heavy form. Its peculiarity as a variety is that it is richly variegated with strong gold-yellow; it is, in fact, a golden tree, a pyramid of superbly coloured vegetation, the richness of the golden hue bringing out with great distinctness the fine red of the bark, and the sombre green of the older leaves and those parts which are not variegated. The coloured figure of the tree, printed by Day and Son, is well worthy of a place in the portfolio of every amateur

arboriculturist. Another of the good things from the Lough Nurseries is a variegated *Cupressus macrocarpa*. This in its normal form is one of the handsomest of garden trees, and most delicately coloured. The variegated form of it is at once rich, decisive, and peculiar; the prevailing hue being orange-yellow, bright and pure towards the points of the shoots, but changing to green at their bases. Some 5000 plants have been propagated of this charming variety, all taken from one tree, which of necessity is now in a somewhat lean condition, but will have done its duty well in furnishing so many counterparts of itself, to light up the choice gardens of the British islands. Another interesting example before us is a variegated form of *Cupressus Lawsoniana*, the prevailing hue of which is a clear amber shading to primrose-yellow. From the sample forwarded, we should conclude this to be a valuable acquisition for decorative purposes, and well adapted to produce surprising effects in ornamental planting.

THE MANCHESTER NATIONAL HORTICULTURAL EXHIBITION proceeds so satisfactorily in its preliminaries, that it is now pretty well assured of success; it can scarcely be marred, in fact, except by some unforeseen and unusual occurrence, such as continuous bad weather or a revolution. No alteration has yet been made, either by the Royal Horticultural Society or the promoters of this exhibition, to remedy the evil of their mutual interference in respect of the last day of one exhibition and the first day of the other. Should the present arrangements continue fixed, we have no doubt exhibitors will find some way out of the difficulty; and those who have promised to show at Manchester will assuredly do so, even if they keep away from Kensington altogether, to maintain their honour. The plan decided upon with respect to the show, is to cover a great space with canvas, equal in extent to three times the area of the large exhibition-house, to enable visitors to inspect the whole without going from under cover. The railway companies have consented to carry goods for this exhibition at the rate of a single fare for the double journey. Manchester itself can show something in the way of horticultural power, for the suburbs of the city abound in well-kept gardens; and it will be a great benefit to the wealthy patrons of horticulture in the district to be placed in competition with the foremost exhibitors of all parts of the kingdom, and to see, side by side with their own productions, some of the best collections of exhibition subjects known. We have but to wish the undertaking the most complete success, and this with the more pleasure that the profits are to be applied towards the reduction of the debt upon the Botanic Gardens, a debt not quite creditable to the wealthy city, which, as much as any place in the empire, needs the influence a botanic garden must exercise in counteracting the materialism of a busy trade and excessive work. Mr. Findlay, the curator, who has done wonders for these gardens, appears to be the guiding spirit in the promotion of this exhibition. In his able hands may well be confided all that it is his part, and all that he has engaged to do.

CULTIVATORS OF PANDANADS will find much to interest them in a "Revision of Indian Screw-pines," by S. Kurz, Esq., in the April No. of the *Journal of Botany*. As a contribution to systematic botany, this paper is of the highest value and importance.

A HYBRID PALM is at least a novelty, but doubtless it is a fact. It is reported that M. Denis, of Hyères, has succeeded in crossing *Chamærops humilis* with the pollen of *Phoenix dactylifera*. The result is a plant combining some of the characters of both parents, but in which the characters of the male parent predominate; but the fruit (the immediate result of the artificial fertilization, not the produce of the hybrid plant) is strictly intermediate between the two.

MODELS OF ORANGES GROWN IN NEW SOUTH WALES are prepared for the Paris Exhibition of 1867. Samples represented by these models weighed respectively 22 ounces, 22½ ounces, and 25½ ounces. Two oranges grown on a single stalk in the orangery of Mr. George Oakes, at Paramatta, weighed together 32 ounces.

SOME BLIGHTED SPOTS IN ENGLISH GARDENS.

I have noticed, not alone in the English gardens, but in all parts of Europe, spots which do seem under a spell, and quite unproductive of vegetation. But I shall now only think of the English gardens, as I am writing this, to the best of my knowledge of your language, for the English reader. But it is to him who is a lover of beauty and who is the friend of improvement that I am now addressing, and we shall, if you please, walk through a garden together. You will see that the gardens near to great cities have most of the blighted spots, but some in the country are bad equally; so let us walk in a garden, whether it be town or country. What shall be said shall be to both useful. Now we are in the entrance, which is a court leading to an open platz before the house. Stop, stop, you are in such hurry; you have already dragged me past one of the blighted spots. Shall I not, keeping eyes open, and find what I am seeking? See here, in front of the long wall, and as an adornment to the path, are large bushes of *Aucuba Japonica*, *Holly*, and *Phillyrea*. I admire this much; it is a noble entrance, and within view in every part of this property are noble trees. But all the ground beneath the trees in the border between us and the wall is bare; you see that it was once edged with box, for there are a few scraps still living, but as an edging the box is gone, and perhaps many things that were originally planted in the border have perished in the heavy shade of the trees. Now I can clothe all that ground with beauty; I can make the skirting of the walk equal to its upper line, which is so good with trees and shrubs. I would first take away the few remains of the withered box-edging, that none shall say there has been a failure here. Then I would mark out a new line, to give the border greater width—that is, I would encroach upon the walk, which is ample, for the sake of forming a new edging somewhat in advance of the drip of the trees. But I want no new soil, I want very little; surely, if I want much, I shall not be allowed to clothe with beauty the blighted spots in English gardens. Now then I make a new edging, and it shall consist of little plants of *Euonymus Japonicus*. This is

secret No. 1. Now I hope it will be esteemed, for it cost me many years of experiment with various subjects to discover what would live in the shade of trees, and take the place of box for edging, and I can say that the *Euonymus* will do it; so if a green edging is desired in a great court where the trees are large, the reader will know what to do. In winters of such severity as 1860-61, and 1866-67, the *Euonymus* might be cut down by frost, but the next thing would be to cut it down with the knife, and in the next summer a fresh growth would arise from the roots, and the edging would replace itself. Now I shall tell you of other ways to make edgings under great trees. Gather a lot of holly-berries at the close of the year, and lay them in a heap mixed with sand, and thatched with straw. In the following March sow them in drills, in light sandy fibrous soil—not in loam if you can help it, but you may use peat or leaf-mould if you can; in some places fibrous soils are as plentiful as in others they are scarce. What I have always used for holly-seeds was a thin slice taken from a sandy waste, this thin slice consisting chiefly of fine grass turf, which was laid in a heap to kill the grass. Being sown on this kind of soil, the young plants may be lifted with abundance of fibres, whereas in loamy soils they soon form tap-roots, which are objectionable. In the month of May in the first year after sowing the seed—that is to say, fourteen months after sowing the seed—take up all the strongest plants and transfer them to your edging, but do not disturb the seed-bed, because many of the seeds do not germinate the first season. Make the edging with care, and if the soil is not good, use plenty of rotten manure and leaf-mould; the *Euonymus* will grow in any soil, but a hedge of seedling hollies should have something good to grow in. If you do not want all this trouble, go to a nursery and buy as many hundreds or thousands of three-year-old hollies as you will require; plant them in April or May, and as soon as they are planted, put down a line and cut their tops to it; the shears must not be used, but a knife, and the line must be put so that there will be no need to cut severely, as in the diagram, where A is the line, B the hollies, C the few tallest leaders that have to be cut.

Yet once more with this entrance court. More cheap and effectual than all else would be an edging of ivy. The common *Hedera canariensis*, which is here absurdly called "Irish Ivy," would answer well. The plants would have to be planted a yard apart, and trained and cut as required. In a small garden the ivy I should prefer is the Taurican, or *Hedera helix Taurica*, which is rather small, very rich green, and glossy. We shall suppose now that the edging is disposed of. Then I would plant in the best of the open spaces under these trees the following, to cover the ground: *Taxus adpressa*, a neat tabular-headed yew, which will thrive in very deep shade if the soil is strong loam or clay, but is no good in a sandy soil; *Ligustrum ovalifolium*, the oval-leaved privet; *Berberis dulcis*, the best of the race for places much shaded, and for any kind of soil (many other *Berberis* like shade, but generally speaking much judgment is required in planting them—at all events, I will not recommend the lovely *B. Darwinii* for the purpose, for I never saw it thrive except in an open peat bed); *Hypericum calycinum*, a pretty dwarf St. John's Wort, will grow anywhere under trees, and will be always spreading and improving in beauty; the common holly, *Ilex aquifolium*, and the noble dark green, very distinct "twisted-leaved" holly, called in the nurseries *tortuoso*, are the two best of the race for such places; the common *Daphne lauricola*; every kind of Butcher's Broom, *Ruscus aculeatus* and *Ruscus racemosus* being the best; also Periwinkle, *Vinca major*, and common Juniper, *Juniperus communis*. I shall quit this border by offering a hardy herbaceous plant that looks like a shrub. I shall call it the poor man's shrub for blighted spots, because one bit as big as the finger may in time be increased to cover acres; and though it is invisible in winter, its growth all the summer is like an evergreen shrub. The plant is *Aster fulvis*, a small-leaved dark green plant, which in October produces heads of pretty small copper-coloured flowers, but requires a sunny place to flower well. This, then, is a good subject to plant in a blighted spot for the sake of its foliage only.

Now I will go on with you. How neat, how bright, how harmonious is the scene! Surely we cannot find another blighted spot. Ah! here is one. Observe how these trees overhang the grass and kill it, so that on the margin of the lawn there are great semi-circular spaces covered with moss. Now, if the moss there were nice green moss, such as we find in woods, I would leave it alone; but it is ill-looking, more black than green, and is altogether sour and unsightly. The gardener says he can't help it; the grass never will grow there. Well, I know that; then why not try something else? I can see, by the fine grass in the open spaces,

and the vigour and health of the trees, that the soil is all right. I never want to dig up the soil to discover its quality; what I find growing on it will always tell me what it consists of. Now I shall say that the appearance of these bare places is most objectionable, and we must sacrifice formality for the sake of beauty. We will not alter the shape of the lawn; it is not my business to alter any one's designs, but we will cover the ground where the grass will not grow. First, then, I will have these places well dug and manured. Next I will plant them, about a yard apart, with tufts of *Ranunculus ficaria*, which you call the "small Celandine," also with the "Enchanter's Nightshade" (*Circæa Lutetiana*), with Russian violets, and English primroses. You may perhaps think also of periwinkle and ivy, but these I do not name, because they are too dark in colour. The plants I offer for the purpose will quickly spread, and make beautiful sheets of bright green herbage, in most perfect harmony with the grass all around them. The first two plants may not be known to all the readers of this; they are most common, most beautiful, and spread fast and luxuriantly in damp soil under trees. The Celandine produces at this time of year numbers of lovely golden flowers, far superior in beauty to any of the meadow ranunculuses. Another reason for naming these four subjects is that they may be mowed, if desirable, after spring is past, but I do not advocate mowing them; rather I would take the machine close enough just to touch them where they seem likely to encroach on the grass, so as to keep them to their proper districts. Nevertheless, if at any time late in the summer or autumn it is found desirable to pass the machine over these places, it may be done if the cutter is set high, so as only to shave their tops, and not cut close to the earth.

Now we have got upon the improvement of the lawn, the proprietor asks about the south bank or glacis on the further side, where from the terrace-walk we look down on a geometric garden. This south slope is so hot and dry in summer, that by the end of June it always turns brown, by the middle of July is quite brown, and thence till the end of September unsightly. It strangely happens that the soil here is quite sandy and poor, so there are two obstacles to the growth of grass. It has been several times sown with clover, but though this promised well for a time it perished at last. Now I can face that slope with as bright green grass-like herbage as can be found in the world, and I advise that it be planted with camomile and common yarrow. As vulgar names are not to be trusted, I wish it to be understood that the camomile I mean is the *Anthemis nobilis*, and the yarrow is to be *Achillea millefolium*. These may be mown like grass, and will continually spring again from the root; but the wise gardener will never mow hot dry banks and slopes very close, or very frequently, for in such places herbage lives in summer chiefly on dew, and if closely shaven, there are not sufficient condensers of dew as when there is some amount of leafage surface to attract and collect the watery particles. There is a much-contemned plant that might be frequently used to improve lawns, especially where the soil is damp and sour, and that is *Sagina procumbens*. To obtain it is easy enough, for it makes its appearance everywhere—in flower-pots, in little tufts, and on bricks, and in odd waste corners—not in England only, but all over Europe. I have never been in a garden but I could find it somewhere. Indeed, I have known many gardeners to call it Spergula; but the true spergula is a different plant, and a more elegant, but not so accommodating as this to form a close bottom amongst grass. If it is ever wanted in quantity, a bed or nursery should be prepared for it, and the best soil is that thrown out from flower-pots. When to be used to improve the lawn, it should be dibbled into the ground during showery weather in April, after the first mowing has been done. Roll the turf immediately afterwards, and the Sagina will soon begin to spread and increase.

Now we shall find in this garden some spots that, being near a rockery, a root-house, and some old brick structures, are so much infested by vermin that very few herbaceous plants thrive in them. But I can tell my friend of a few good things that vermin will not readily touch, and that may be planted under the shade of trees, and that will take care of themselves for ever. And I shall now in thought transfer myself to the garden of the poor man, in the vicinity of the town, for he has to contend with smoke, walls, trees, snails, and wood-lice. To him I would say, have a free current of air by all means, but consistent with that have as many trees and shrubs as possible; for a garden may be rich and delightful where they are, but cannot be so where they are not. I would rather have one fine birch or plane tree, or even apple, pear, or elm tree, than ten thousand flowers, if I could not have both; but that is my taste, and may not be yours. Nevertheless, I tell you now of a few beautiful plants that may be put in borders where shade, confinement, and vermin commonly destroy your pansies, asters, dahlias, and even your pretty *Saponaria ocymoides*, and other lovely borderers. First, then, the most beautiful *Ranunculus ficaria*, which I have recommended for the lawn. Put little bits of it everywhere in borders under trees, and leave them to spread. In the month of April every year they will shine with emerald green and purest

gold, and when they make large patches will be worth inviting friends to see, especially while the sun shines. I do not advise much use of the Enchanter's Nightshade now, because it runs and spreads much, and is not showy; yet it is quite acceptable to cover the ground in quite dark places where not even ivy or periwinkle would thrive, and it is neat and pretty. Next, we have choice of all the varieties of *Primula vulgaris*, some thirty in number; and lovely as are the double pink, double white, and double yellow, the common single yellow is a real gem, that bespeaks the plentifulness of beauty in the gardens which the Lord has planted; for He makes it to grow as a diffusive weed, in company with the violet and the pimpernel, and that sweet-scented weed the Wood-ruff or *Asperula odorata*. All the species of *Lysimachia*, and especially two, the *Lysimachia nummularia* or "moneywort," and the *Lysimachia thyrsoiflora*, a fine, bold, shrub-like plant, which spreads and spreads, and flowers richly all the summer, showing amongst the bushes its fine thyrses of yellow flowers. Then there is the Lily of the Valley, *Convallaria majalis*, which I am told many English gardeners cannot grow; but I say from experience that if they will now take up a quantity, and tear the roots asunder, and plant the pieces in all parts of the shrubbery, quite covering the crowns that are now rising (the end of March is a better time though), they will in a few years take hold of the soil and spread extensively, forming the most lovely summer surfacing that can be imagined, or that has ever been seen. The *Alchemilla pentaphylla*, *Alchemilla conjuncta*, and *Alchemilla vulgaris*—these are most beautiful plants, equally elegant in leaf and flower. The quaint Hoffman reports upon them, that they possess the power of preserving beauty, but that no plant has; but the love of plants may tend to preserve the beauty of the soul by keeping us in mind of the presiding Maker, who, in His infinite goodness, has clothed the lily of the field with more splendour than was seen in the gorgeous robes of Solomon, once greatest of Oriental princes. And here I am reminded of a most elegant plant, the Solomon's Seal or *Polygonatum multiflorum*, which I have seen grow with a vigour and beauty few plants could equal, in spots where it appeared a miracle a plant should live, and no snail or oniscus will touch it. There are many more species of *Polygonatum* which the amateur who wishes for variety may plant with satisfaction: I would name especially as worthy of a place in the choicest garden, *P. ambiguum*, *P. latifolium*, and *P. multiflorum fol. variegata*, which is one of the rarest gems of variegated-leaved plants, but very scarce, and I know of no one who has it, though I have seen it many times. But let us proceed. The Artemisias will live where many other plants will not, and are always most elegant in their aspects. Say, for the sake of being definite, that we put down *A. maritima*, *A. pontica*, and *A. vulgaris*. Of the last there is a variegated-leaved variety, which should be allowed somewhere to extend and form a great patch. *Epilobium hirsutum* and *E. angustifolium*, and the variegated-leaved varieties of both, are quite proper for such places, and though generally recommended for damp soils, they will thrive on quite dry spots if planted early in the spring, so as to have the summer to extend their roots, and form good crowns for the next year. The Day Lily is the next thing. The botanical name is *Hemerocallis flava*, a most beautiful plant, whether we consider its graceful light green leaves or its gay lily-like flowers. There are a dozen kinds in cultivation; and on a border near the windows, but where many trees preclude much planting of flowers, all the kinds of day lily should be planted, and every year thereafter they will increase in size and flower profusely. Of the Hawkweeds, *Hieracium pilosella* will be useful. *Spiræa ulmaria* is not to be despised, though I do not see it flower much when in a shady place; indeed, it is by the river's brink that it seems to be most at home, but as a green tuft it is of some value in the shady border where vermin abound. Of the violets the best for very shady places are *Viola cornuta*, *V. lutea*, a charming yellow flower, not much known, though common all over Europe; *V. obliqua*, which has a twisted flower; and the Russian variety of *V. odorata*, which grows and spreads, and makes beautiful tufts of herbage, but only flowers well once in three or four years unless skilfully cultivated; and you know that one part of skilful cultivation consists in propagating annually, and planting the young plants in fresh rich soil. For my part, I would rather see great patches of such a plant consisting of leaves only, than the bare, sour, ill-looking spots that are neglected because the shade and the vermin render it impossible to clothe them. Impossible! that word is for the incompetent, the idle, the careless ones who take refuge in a word from the obloquy that belongs to their paucity of noble deeds. It is impossible to take an army across the Alps; but Napoleon Buonaparte, greatest of leaders and worst of men, did it. Impossible! All that I have said herein is possible, and I hope it will be useful also. I had almost forgotten to advise the possessor of a shady border to sow at this time of year, or some time before Midsummer day, plenty of seeds of the columbine *Aquilegia vulgaris*, and allow them to spread and grow as they please. In truth, seeds of all the kinds of *Aquilegias* may be sown under the

shade of trees, and very few if any will fail. And what will be the result? Lovely tufts of most neat and attractive herbage in spring, soon followed by charming flowers, and these flowers will shed their seeds, and more and more plants will spring up every year.

Borders occupied with such things as these should not be dug: the gardener who digs such borders is—I will not use unkind terms, but I mean them, and as many as can be imagined. I have seen in some of your London gardens the spade used in borders where I was told there were many lilies, pæonies, and other herbaceous plants; and I have said, "You had best take farewell of your lilies, pæonies, and other herbaceous plants, for they are now being executed, though innocent of wrong, and without the sanction of either judge or jury." Dig not these borders. But few weeds will ever grow in them, and such as do appear must be removed by hand-fork or trowel; and to give a new surface wait to the end of March or middle of April, and then slightly break the top crust with a small hoe, taking care that in the operation not a leaf is hurt. If they are left to me, however, I will not even hoe them; for nature does not hoe the ground in the great woods, where for the most part such things grow, but they are covered with leaves all the winter, and in spring break forth as it were singing—certainly they break forth smiling while the lark is singing, and when we should be singing too, with the Spirit of the Lord upon us to bind up the broken-hearted, and deliver them that are bound. And once more the woods and the leaves remind me of the hyacinths—such as *Hyacinthus non scriptus*, in its blue and white varieties—which are at home under trees, and at the present moment are displaying their beautiful racemes of flowers. I have not seen this plant in English gardens, except those that belong to the poor; the rich do not know of its adaptation to make sheets of white and blue, and even of pale rose colour, under trees in the month of April. I saw some of it lately in a cottage garden, and I said within myself, "How many thousands of pounds have been expended on flowering plants that have not rewarded the disbursers of the money with flowers of beauty equal to these!" But that is no matter. Some value plants for their cost. I value them for their use and beauty, and if there be a story woven into the thread of their simple lives, the delight is the greater. Now, in the opening spring, we see some of the loveliest forms of vegetation pertaining to our native climes. If so poor a pen as mine could set forth their beauties and expound their influence on the human heart, how gladly would I labour for this. But to be silent is better than to load the page with inelegant reflections, though, having the works of De Lisle before me, I can transcribe a few lines that are appropriate, and may entertain the reader, and especially the reader who loves as I do the tangled maze of Flora's wilding wreath, and the nearest approaches that can be made to it in the enrichment of the garden:

"Ye gentle shades between the trees and flowers,
With you, ye laughing race, I'll deck my bowers.
Oh that my theme would grant the fond delay,
Nor with too urgent haste forbid my stay!
With what delight my hands each spray should guide,
And teach your curling tendrils where to glide.
In woven bowers and roofs your shoots should grow,
And 'neath your network arch the riv'let flow;
Around your elm your wedded arms should wind,
Emblem of strength, with gentlest beauty joined.
You, then, to whom their lovely pomp is given,
Display with art these charming gifts of Heaven;
Let every season have their brilliant bloom,
Their laughing colours, and their rich perfume:
Let each in turn the well-wrought chaplet wear,
Thus ne'er shall fade the garland of the year;
But new-born joys shall every season bring,
Each month a bower, and every bower a spring."

I did not observe till I came to transcribe this its complete appropriateness to the subject. It anticipates our ideas and warrants our assertions. KARL PROSPER.

THE GLORIOSA OR CLINOSTYLIS.

A vast number of plants of all denominations get a long grand-sounding name tacked to them and started out into the world, which very probably they by no means deserve, or in any way bear out the relationship which is naturally supposed to exist between the plant and its name; but this truly beautiful plant is one of the exceptions, for every one acquainted with its merits will admit that it most conclusively establishes its claim to the appellation conferred upon it, for it is indeed a glorious thing when well done. There is not a stove in the three kingdoms, or a collection of stove plants, however select, whether hard or soft wooded, that it would not be a very valuable and grand acquisition to it; yet, notwithstanding its extreme beauty, it is by no means extensively cultivated. I must admit that one cannot grow everything that is really good, for it would require a regiment of gardeners and several acres of glass to do so; while admitting this, I am of the opinion that it could be introduced into scores of collections with immense benefit, where the space required for its cultivation is at present occupied with

plants far inferior in merit to it. Few plants which are employed for training up the rafters and roof of the stove have a better appearance, or produce a richer effect, than this does when in bloom. For covering large spaces it would not be fair to put it in competition with fast-growing plants like the *Stephanotis* and passion-flowers, for it is not so suitable. My favourite way is to train it straight up the rafter: it shows the flowers off to a far greater advantage that way than any other; it also looks very well trained over a trellis, which is the way it must be trained if the plant is required in the conservatory during the time it is in bloom. Whichever way it is determined to proceed, it should receive attention immediately the young shoots get a few inches long, for they are very liable to get broken if they are allowed to hang about over the sides of the pot until they are several feet in length.

The *Gloriosa* is propagated by seed and division of the roots when the old tuber is shaken out of the old soil, and repotted in the spring. With careful impregnation, which is a very easy matter, it will produce a few seeds, which require sowing as soon as properly ripened, and a moderate amount of care bestowed upon them. For the first potting, in March or April, I prefer potting the bulbs in rather small pots, and then as soon as the pot is nicely filled with roots, and fairly started into growth, shift into a larger size. My opinion is that they do much better than when they are potted in the blooming pots at once; they root better, and when the plant feels the fresh soil it goes away with amazing rapidity. It is a great advantage to give the bulbs a nice bottom-heat of about 75°, if it can be conveniently done; it will enable them to push out much quicker and stronger. For the first potting, sandy peat, leaf-mould, and loam will be suitable, and for the final shift, some good fibry loam and rotten manure. If the loam is deficient in fibre, use a little peat to keep the soil open. Let the first soil be moderately moist, so that no water will be required until the young shoots make an appearance above ground, when they will require a little at first, and increase it in proportion to their growth. The temperature of an ordinary stove, with plenty of atmospheric moisture, and potted in the above-mentioned soil, will grow the *Gloriosa* to perfection. After the plants have done flowering, and the leaves begin to change and turn yellow, they should be dried off, and the bulbs put away in a cool part of the stove where they can be kept perfectly dry until the following spring.

I cannot occupy space with a long list of species, for I know of two only, *Plantii* and *superba*, and both are good.

GEORGE GORDON.

SHRUBBY CALCEOLARIAS, AND THEIR CULTURE AS POT PLANTS.

There are but few florists' flowers that better than these repay for the time and pains bestowed on them, when grown as specimen plants for furnishing the conservatory. Their varied, and always richly, and sometimes curiously coloured flowers are highly attractive, though not so large or so fascinating as the flowers of the herbaceous section. Yet they are far more useful to furnish cut flowers, and last a great deal longer after they are cut, their close compact heads of bloom favouring them for such a purpose, as contrasted with the herbaceous varieties. Even *Aurea floribunda*, the pet of our bedding calceolarias, when cultivated as a pot specimen, is in every way excellent for making the greenhouse or conservatory look gay during the late months of the spring. Perhaps one of the most important of the many reasons urged against their general pot culture, is their liability to suddenly droop and die off. We will attempt to explain the causes of this, so far as we can make them out, and also suggest such remedies as we consider to some extent would counteract the evil. First, we would say, exercise great caution in regulating the supply of water. Too little would be the lesser evil of the two, as compared with an excess; for should the plants become so thoroughly soaked as to be for any time water-logged in their pots, the healthy action of the roots must be checked, and the consequences must be fatal. Again, if allowed to suffer from drought, the result would be scarcely different, although by an after supply of water to the roots they may apparently revive, yet the chances in their favour are but as one to ten against a satisfactory recovery. Now comes the question, How are we to prevent these casualties? Why, by being attentive in watching their necessary requirements, and so using our judgment by regulating the supply of food and drink to the plants, and also keeping them very clear of insects of every kind. The latter advice should be rigidly adopted by fumigating them at least once a fortnight.

When potting them, put a thick layer of half-decayed manure over the drainage; cow-manure is the best, if obtainable. Such practice affords their roots a cool nourishing food. Before using it, examine the manure well, and pick out all worms that you can find, for should they be harboured in the soil or manure, evil consequences must ensue, for the constant activity of the worms would choke up the drainage.

It is advisable always to have duplicate plants of all the sorts you may cultivate, in case of an accident. When you stop the shoots, put the tops into a prepared pot of soil. They are not long before they become rooted, especially if they are covered with a hand-glass, so that air is shut out. The autumn is the most favourable period for successfully propagating all the varieties of the shrubby species.

When rooted, pot them off singly into small 60-sized pots, and put them in a close frame. If they are subjected to a gentle warmth in the first stage of their rooting, it is so much the better. As soon as they have grown sufficiently to admit of being stopped—that is to say, so that you can ensure from four to six breaks from the main leading shoot—take the point out of the leader; then, as soon as the new shoots have commenced pushing, shift them into one size larger pots, or, if they are well furnished with plenty of roots, you may put them into a pot twice their present size. As they grow, carefully train out each shoot, so that they may enjoy plenty of light and air, which will tend to strengthen them. When the increasing growth is allowed to crowd in a mass together without training, the thickening leaves afford to some extent a shelter or nesting-place for the breeding of insects.

In training them use caution, for they are brittle and soon snap. That you may in some degree avoid that, first secure the lateral shoots with bass to the main stem, or the centre stake that supports the plant; this will prevent the branch from severing from the stem.

The principal object of the cultivator should be, if he is desirous of obtaining large specimens, to encourage a rapid but healthy growth; and this can be done by endeavouring throughout all the stages of their career to maintain a moist and mildly warm atmosphere, admitting plenty of air on all favourable occasions, but avoiding sudden cold draughts. If the plants are progressing vigorously, they can be successfully shifted from a large 48 to an 8-inch or 24-size pot. It is useless to continue to shift after they have shown the least disposition to flower, as whatever shoots they make afterwards, flower-buds are sure to appear with them. A gentle syringing when they are shut up of an afternoon will be very beneficial to them, especially at the close of a warm sunny day. When in flower, keep them shaded from the hot rays of the sun. If they exhibit signs of being pot-bound, we then suppose that they have exhausted all the nourishment contained in the soil, and should they be in their flowering-pots, it is prudent to water them occasionally with liquid manure; but cease to apply this when the trusses are somewhat developed. Endeavour to keep them thoroughly clean, by continuing to fumigate them up to the period of their commencing to flower. If you fumigate after they are in flower, the chances are that the fumes of the tobacco will cause the majority of the blooms to drop. The compost most suitable for growing them in is a friable turfy loam, such as the top spit of a pasture that has been stored and turned at intervals, to which add about a fourth of leaf-mould or good old decayed *cow-dung*, with sufficient silver sand to render the whole porous. It will be all the better if you add about an eighth of peat-earth; but still that can be dispensed with. The following list will be found to contain some useful sorts, all of which I am at present growing.

Names.	Colours.	Remarks.
<i>Angustifolia Superba</i> ..	Deep yellow	Dwarf habit.
<i>Beauty of Heris</i> ..	Clear amber	Dwarf habit.
<i>Bird of Paradise</i> ..	Bright orange spotted	Free branching habit.
<i>Beauty of Montreal</i> ..	Bright crimson	Small flower, but effective.
<i>Canariensis</i>	Bright yellow	Compact habit, very dwarf.
<i>General Tom Thumb</i> ..	Deep yellow	The dwarfest variety in cultivation.
<i>Princess Alexandra</i> ..	Rich orange buff	Dwarf, compact habit.
<i>Magnificent</i>	Crimson	Large flower, and good.
<i>Etna</i>	Crimson-scarlet	Very free, rather long flower stalks, good for bouquets.
<i>Lillio</i>	Bright yellow	Very good and effective, forces well for bouquets.
<i>Victor Emmanuel</i> ..	Red scarlet shaded	First-rate.
<i>General Havelock</i> ..	Fine bright crimson	Excellent and long lasting.

JOHN F. McELROY.

IDER-DOWN.—A consular report of this year on Iceland gives an account of the way in which down is exacted from the cider duck. Early in June, the bird, always repairing to the same spot, comes to some small holme or islet in a bay or fjord, and lays its eggs, after lining its nest with the down plucked from its own body. As soon as the eggs are laid, the owner of the hatching-ground robs the nest of the down and a part of the eggs, both of which the poor bird replaces a second and a third time, when she is left in peace to complete the process of incubation, but with her body completely denuded of down. This method is adopted because the down of the dead bird loses its elasticity, and is of comparatively little value. The hen-bird gives eight or nine ounces of down to a nest, but when cleansed the weight is diminished by half. The value of the cleansed down is about 19s. per lb. The annual produce in Iceland is valued at about £5,000. In some instances one small holme will give its owner an annual income of £150. Such is the care taken of these birds that during the hatching season no guns are allowed to be fired in their vicinity; foreign vessels arriving are forbidden to fire salutes.

KNOCKHOLT BEECHES.

This has been a very unhappy sort of a day; my men have been unable to work on account of the continuous drizzling rain, which has been falling throughout the whole of the day; so, to save myself from stagnation with cold and ennui, I took my umbrella after dinner, and walked up as far as the famous Knockholt Beeches. This is a fine clump of beech-trees, growing on the highest point of land in the county of Kent. I am told that they can be seen from the sea, although forty miles distant. I have had them in my eye for many months past, as they form a prominent feature in the landscape of this part of the country, as seen from Chislehurst Common, and I have often wished for the opportunity of a nearer inspection. This opportunity has been twice afforded me. Once, six or seven weeks since, when the ground was thickly covered with snow, and every bush and tree was beautifully incrustated with rime, sparkling gloriously in the sunlight; and again to-day. On both occasions the atmosphere has been filled with mistiness, so that I have been quite unable to distinguish the configuration of the surrounding country as seen from this point, which, as may be easily imagined, is very extended and varied. I can therefore do nothing more than make a few notes on the clump itself. This consists of ninety-five large trees, the tops and branches of which commingling form one dense, twiggy mass, which even now, denuded of foliage, are a dark, imposing object, standing out in bold relief against the sky from every point for many miles around. Fourteen of these trees appear to be of very great age, probably not less than from 500 to 700 years; some of these are very much torn and gnarled with the storms and battling with which they have had so long to contend, and to the full force of which they are constantly exposed by their unsheltered and elevated position. I should say that the remaining eighty-one trees are seedlings from the older plants, as, from the exceedingly irregular way in which they are disposed, it seems impossible that they should have been planted. Another reason why I think these younger trees must be seedlings from the older ones is, that the whole surface of the soil, both in the interior of the clump and on the outskirts, is covered with young beeches of various ages, and different heights and stages of growth, so that, as any of the larger specimens decay, blow down, or otherwise lose their position from the main group, others are pushing themselves up into their places. The ninety-five trees are those which by their uniform height and growth do constitute what in common parlance are called "The Beeches." The moralizer would be very much interested while surveying this group at its resemblance to human society. Here are fourteen grandsires, so to speak, beginning to manifest signs of decrepitude and decay. Surrounding these and intermingled with them, eighty-one adult specimens of ages varying from one to three or four hundred years in their prime vigour, while on every hand saplings of every age, from the infant just out of the soil to the hobbledehoy, between a man and a boy, abound on every hand. The whole of the trees composing the group, with one exception, are fine, straight, upright boles, averaging eighty feet in height, or perhaps more. I don't know whether there is any tradition about these trees, as to how long they have existed in their present form, how they came here in the first instance, or whether the surrounding country was all forest and the surrounding trees cut away and these purposely left for a landmark or seamark, or what not. I may some day or other have the opportunity of learning. The length of the clump from outside stem to outside stem is 137 yards, the breadth about 60. The shape may be called a pot-hellid oval, a sort of monster egg.

There are three excavations, two of them being fifteen or more feet in depth, in the bottom of which and on the sides some of the largest trees are growing, while the third is a circular hollow, five or six feet in depth, containing a nice group of young trees, say of forty years' growth. The soil in which they are growing resembles much of the soil of this neighbourhood, and consists of a dark-red loamy clay largely intermixed with flint-stones, as large as two fists, and is of a nature to sustain trees of the largest growth. The undergrowth among the trees has nothing remarkable—a few scattered hollies, brambles, and honeysuckles thin and poor in their growth, are everything at present visible, with the exception of moss, which covers the ground with a bright, green, soft carpet, far surpassing in beauty and finish Turkey or Kidderminster. I think, Mr. Editor, you would be just in your glory if you could on some bright, clear, sunshiny day come down and roll yourself upon the moss among these trees, and enjoy the beauty of the surrounding scenery.

Knockholt, Kent, Feb. 26th.

WILLIAM CHITTY.

GRAPE-VINE TRAINING.

I am glad to find you continuing to advocate so powerfully in *The Farmer* the long-range system, as I may term it, of grape-vine training, which you brought prominently into notice last autumn.

I have for many years been convinced of the absurdity of the so termed "spur system," although no doubt vines will, under such treatment, bear very well during the first three or four years, while their roots and branches are more equally balanced; but gradually afterwards, by the unmerciful lash of the knife, they are, like a cruelly over-driven young horse, soon on their last legs. In corroboration of this, I may state that about four years ago we had a viney here, that after enduring the unnatural spur torture for many years, and yielding at the best about a third of a crop, I, in faith of giving liberty to the vines, cut out by the roots every alternate plant, thus leaving one vine only to every alternate rafter.

In pruning I then cut away all the spurs, with the exception of leaving a pair of branches at about 3 feet apart up the main rod, and these young shoots I trained horizontally along the wires. And now these vines go on regularly yielding double the number of bunches required to be left for a crop, and all perfectly coloured and entirely free from shanking, which was not the case while they were subjected to *vegetable bondage* under the former system.

The prevailing system of grape-growing may, in my opinion, be compared to a thickly planted and regularly dressed *thorn hedge*, the plants of which, in a comparatively short period, get stunted and die out; and as to the remarkable crop of *haws* on said hedge, who saw them?

Much is now being said and written regarding reform in our Parliament, but truly we gardeners, who pretend to control the vegetable kingdom, have as much need to grant universal suffrage to the vine.—Peter Murray, *The Gardens, Taymouth Castle, in "The Farmer."*

A RALE BULL.—An Irishman, passing through a field of cattle the other day, said to a friend, "Whenever you see a herd of cows all lying down, and one of them only standing up, that one is sure to be the bull."

PARIS INTERNATIONAL EXHIBITION, 1867.

with us in hoping that long ere it closes it may be unanimously pronounced a brilliant success.

We present a rough sketch of the building, as far preferable to the most elaborate description. The site occupied is on the margin of the Seine, on the spot so well known as the Champ de Mars. Originally the ground was some feet lower than the surrounding roads; but on the opposite side of the river was a mound (lying between Paris and Passy) called the "Troadero." Rails were laid down from the hill to the hollow, by way of the bridge which connects them, and in the course of time the mound disappeared, by the transference of its substance to the Champ de Mars, the level of which rose sufficiently for the purposes of the architects. The Exhibition, therefore, is built on made ground, and for that reason its very foundations are interesting; and when we state that the area which it covers is three times as large as the Exhibition at Kensington in 1862, it will be understood that the preparation of the ground was at once a curious and a gigantic undertaking—the removal of a mountain, in fact, to fill up a valley—fulfilling in a peculiar manner a scriptural expression as regards the two sites operated on, that the valley shall be exalted and the hill made low.

The building measures 1,600 feet by 1,250 feet. In general configuration it approximates to an ellipse. It consists, as may be seen by the figure, of a concentric series of courts, connected by transverse arcades, enclosing in the centre a garden, with flower-beds, fountains, and statuary. This garden, indeed, revives the idea of the inner garden of the old Roman mansions, the pleasing adornment of the colonnade on which the rooms of the basement opened, and which is so admirably represented in the model of a Pompeian villa in the Crystal Palace. In the case of the Paris Exhibition,

however, we have a space of 500 feet long by 200 feet broad, forming an elegant finish to the plan, and an agreeable place of resort to visitors who have become weary with the exploration of the courts.

The horticultural exhibition proper is in a portion of the park set apart for the purpose, and comprising an area of about twelve acres. The management of this is entrusted to M. Barillet Deschamps, the chief gardener of the city of Paris. This department will probably be the most attractive of all to the majority of our readers, and we venture to believe that, many and surprising as have been the rumours circulated respecting it, few English horticulturists will be disappointed. We forbear to speak of the specialities of this part of the undertaking at present, for they are as yet but in part developed; but for some time past the fruit garden has been enriched with some remarkable examples of training, an art in which the French cultivators excel, and by which they will astonish many of their English confrères. A very important section of the horticultural department is that devoted to the plant houses, of which there are six—and twenty, all tastefully arranged and connected with a noble conservatory, in the immediate vicinity of which are picturesque winding waters, with cascades, flowery banks, and other elegant accessories. In a short time hence the inner garden will be planted for the season with bedding plants of the richest colours, and with a profusion of sub-tropicals to give the dignity of form. Of these and other matters we shall afford our readers full particulars, in so far as may be necessary to keep the pages of the *Magazine au courant* with the progress of horticulture and its associated arts, in Paris during 1867.

The following are the names of the jurors, in the classes pertaining to the arts of rural life, in Group IX., Live Produce and Specimens of Hor-

PARIS UNIVERSAL EXHIBITION, 1867.

No. I.

The Paris Exhibition is the first of its kind in which horticulture has been regarded as an important feature, and the horticultural departments are fast attaining to such perfection, that they may be expected to prove the most successful, both because of the novelty of the idea and the admirable manner in which it is being worked. That the Exhibition was opened on the 1st of April everybody knows; that there is as yet scarcely any part of it in a finished state is also pretty well known; but no one who has taken any serious interest in the affair can seriously doubt—as some superficial and over-wise people do doubt—that in the course of a few weeks the present chaos will be reduced to order, and that this will prove to be the most complete and magnificent international exhibition of the series that commenced in London in 1851. That first gathering of the nations had the charm of beauty as well as novelty, to render it capable of making the bright mark in our memories it has done. In some respects the Exhibition of '51 will never be surpassed, cannot be surpassed: the world will never again see in the temper of surprise, delight, and emotional ambition for good, with which it then saw the glittering arch rising, like a palace of enchantment, from the bright green grass, toying with the sunshine in the matchless sparkle of its crystal roof, and within made more beautiful than was possible for art merely by the great elm-trees that were enclosed, and that became in time to the minds of all the presiding geniuses of that congress of the nations. But we can turn from the delightful memories of the first great Exhibition to this large affair of the French world without envy and without alarm; and we trust all our readers will join

LONDON GARDENS AND CHURCHYARDS.

We must be practical, even in spring-time, and even upon such a disturbing and delicious topic as the flowers of spring. In truth, we have a little suggestion to make, not altogether without reference to the change in the weather and the pleasant themes which it suggests. Everybody knows that for ten shillings or a sovereign you can, at this time of the year, make the most surprising investment which it is possible to mention on the Stock Exchange or elsewhere. You can plant silver in the ground—or even copper for the matter of that—and grow gold! It is no secret: it has been a perpetual fairy tale, perpetually coming true, since Adam was head-gardener in Eden. You lay your money out in odd-looking seeds and bulbs of various sorts—with Latin names generally spelt wrong—and by-and-by you find your garden all alight with colours and lovely forms; though it be only a tiny patch in London, like that which Charles Lamb used to "cultivate," as he wrote, "with a toothpick and a pair of scissors." Do not say that flowers will not come up in London—look at the window-gardens of poor people, and at the wonderful things which, despite the smoke, have been done in the different parks during the last few years. Why, all last summer and autumn there were Cannas and Sarracenas, the dwarf palm and the castor-oil plant, and many other distinguished foreigners, freely naturalising at the corner of Rotten row. But our thoughts are not soaring to sub-tropical or costly gardening; we speak of the common hardy annuals, which cost no more than a penny or twopenny the packet, and which will, with proper care and management, turn a bare unhappy plot of London soil into a place of beauty. And everybody knows that a little labour at the rake and hoe, water now and then, and half a cart-load of gravel or sifted shells between the beds, will render the effect of the investment splendid. You do not want a large garden to produce it; nothing is so small as not to repay care with beauty. Where nothing else will grow, scarlet runners can; and if you saw for the first time the coral flowers and broad green foliage of the "poor man's vine," how you would marvel that it could ever be a bold and vulgar thing even to allude to such a cookmaid's vegetable! Where, again, will not the nasturtium thrive, with its blossoms of golden tissue, pale or ruddy, and its great flat leaves, which love the light so much, and turn so constantly to the sun? We say—and this brings us to the point—that there is no spot, even in dingy, smoky London, where something pleasant may not be done in spring-time by the help of the flowers.

Why, then, when we are gardening everywhere, should we forget the dismal-looking churchyards, which might so easily be made bright and cheerful, and in some places positively charming? Go down the Strand, go up Drury Lane, into the City, into the suburbs, anywhere about the metropolis, and note what melancholy spots those churchyards are. The soil many and battered flat, the stones defaced and awry, dead cats, broken pipes, and hat-brims all about; and, perhaps saddest of all, a miserable attempt of some consumptive laurels or chrysanthemums to grow, without a chance of success. The graveyards are shut up now, and the sorrow of those who laid their dead there has probably, for the most part, long been robbed of its bitterness; but the ground is surely sacred still, and should be kept with care and reverence. St. Paul's itself is surrounded by a "yard" of the most leprous aspect—a howling-place for cats at night, and offering by day, in its neglected condition, a comment on the gloomy view we take of death. Most of the disused burial-grounds have substantial railings about them, and we will not allow that there is one—including even that of St. Giles's Church or of St. Paul's itself—where bushels of common flowers might not be made to grow for the trouble of putting in a little seed, or planting the space between the graves. If turf and some bright fresh gravel or shells were added, these places, which our Anglo-Saxon mother tongue called "God's acre," might be made to show like pretty little oases in the great city, instead of repulsive, sickly, accursed-looking patches, stamped upon by the hoof of Death's white horse and deliberately rendered barren. It would only need an order from the churchwardens and the rector in each parish to effect the beneficent change. If the plants were once struck, an occasional pot of water, and perhaps a little encouragement in the shape of manure, would be sufficient; and we might then have inside the railings, among the resting-places of "the poor old dead," those sweet blossoms, none of which are too common to serve for illustration to St. Paul's great argument, "that which thou sowest is not quickened, except it die. It is sown in dishonour, it is raised in glory." It would not cost the parishes a ten-pound note in the year to turn the wretched forgotten lumber-holes of death into beautiful nooks, with gay blossoms and green grass among the head-stones, and a wreath of clematis or jasmine, which will grow anywhere, to salute the passer-by with its perfume, and softly veil the names of the dead, who would no longer then be so forgotten. Now is the gardening time; and places like the Temple Gardens show what can be done in the worst of the smoke. Besides, the air of London is slowly improving, as all who grow flowers in it know. At little cost and trouble we might plant flowering trees and hardy shrubs which would make every churchyard in our great city a beautiful sight instead of an eye-sore; while many a sad face passing out from the great crowd to sicken and die would take home from the "places of the dead" a happy instead of an unhappy thought, and begin, perhaps, to guess, before the angels tell him, that golden things assuredly may grow out of Death, as those marigolds and lilies spring from the graves.—*Daily Telegraph*.

To CATCH RABBITS.—Schoolboys in England think themselves mighty clever when they catch birds by putting salt on their tails. Jonathan, however, goes a-head; witness the following mode of catching rabbits: "Place apples on the parts where the rabbits frequent, after sprinkling them with snuff, and when they come to smell, the sudden effort to sneeze which they make never fails to break their necks, and even in some cases has been known to cause them to tumble heels over head a considerable distance; in fact, cases are on record in which, in the convulsion of sneezing, they have leaped into a crust and become instantaneous rabbit pies."

MANCHESTER FIELD NATURALISTS' SOCIETY.

The first mild day in spring, when the slanting sunbeam falls warmly on the "silvery almond-hough," or lights up a sheet of the golden flowers of the little eelandine, causes also a curious stirring in the heart of the lover of out-door nature, and suggests the resolve for a ramble in the country, and the re-establishment of the old fellowship with green things. The garden suddenly becomes increasingly precious, for there are (or should be) myriads of lovely spring flowers there to invite us from the fireside; but of all places to charm the lover of beauty, to fascinate the eye of the artist, and warm the soul of one possessed of a poetic temperament, the woods enjoy pre-eminence. It is under the sheltering care of great old trees, and in the nourishing mould that centuries of decayed leaves have prepared for them, that spring flowers flourish; there we find the ground paved with daisies, violets, and primroses, surpassing ten thousand times the splendour of the grandest Alhambra court, in its green, gold, indigo, and snow-white tessellations, every tint of which is alive, odorous, and apparently full of joy, for each leaf dances to the breeze. It is not the season for elaborated tours and long-prepared-for sojourns, for the weather is capricious; and plans formed during sunshine, when the air is balm, and life has suddenly lost its reality and become a delicious dream, are likely to be mocked at the moment they should be carried out by the sudden return of winter wrestling with the spring, and splashing the pane with an unwelcome wet, and threatening to tear up by the roots the woods that a short while since, in their delicate glimmering of new green, made us think of nothing else than the possible perfections of an earthly state, and the probability of the real existence of fairy-land. Extemporized trips are glorious in spring-time if judiciously carried out, for, with all the accustomed uncertainty of the weather in this sea-girt isle, there is no place in the world where the spring is so rich in beauty, so overwhelming in its food for mental joy and exalted sensuousness. There are no flowers to equal the spring flowers, no verdure like the verdure of spring; at no other time do we see the true grandeur of the trees so advantageously, for their extremest fingery extensions are tipped with gold or emerald, and they shine as if hung with millions of costly gems, and yet their outlines are all displayed sharply, like vast magic etchings, against the clear blue or soft gray sky. Everywhere too, especially in the neighbourhood of an old village, and by the wood-side, the song-birds are swarming and singing, the air is as a voice speaking the praise of God, and we are silent because we cannot soar with the lark in the eye of the sun, and warble like him at the very gate of heaven; or, like the thrush, pronounce a melodious psalm that rises above all other sounds in the vast psalm of nature in the spring. It may be that we hurry out and tread the tender grass for mere diversion, to gratify the love of change, to promote our health; or it may be that we are engrossed in the study of natural history, and are on the search for such knowledge as the things of the season may afford us. But it matters not, provided we accept thankfully the feast that God provides us at this lovely time of year; and he perhaps will be most thankful and most happy who troubles himself least about science, and gives himself up willingly to the spirit of the season, which is tender, affectionate, cheerful, and has but one look and one language—the look and the language of LOVE. We may surely shake off our troubles on a sunny day in spring, if we will give ourselves to nature, and forget the cares that make us pale and thin. Yes, the forest is the proper hospital and sanatorium for a mind distracted with commercial cares and the anxieties of money getting. "Who can minister to a mind diseased?" God alone; and He does minister to thousands of minds that have become diseased through the cultivation of selfishness, by presenting to them a fluttering green leaf, or a timid, restless, musical bird, or a great expanse of heavenly blue, with the glad sun in the midst, warming nature into new life and love and song. These spring leaves are the soul's best medicines. They are the gifts of our Heavenly Father, whose Son has admonished us to behold the lilies of the field, and who, during His earthly pilgrimage, was constantly deriving from the aspects of nature the simple illustrations of his wondrous teachings. Shall we speak of the love of nature, and forget for a moment that Jesus Christ spoke with unapproachable affection and poetry of the beauties of the world—of the ravens that are fed by God, of the lilies that toil not, of the sparrows that are provided for in the vast scheme of providence that embraces the economy of countless millions of worlds? Yes! the country is the health resort of the soul equally with the body; and a religion that ignores its attractions, and calls this world a "vile world," is blasphemy in practice, whatever gray theologians and harsh sectaries may say. When cares multiply, go to the woods,—mayhap you may leave all your cares there, at all events you will be freed of their weight; for the fresh air, and the blue sky, and the tender green, and the wayside flowers, are so many elements of enchantment; and the true elixir of life is to be had for the asking direct from the Divine Disposer of our fortunes.

Oh! forest deep and gloomy,
Oh! woodland, vale, and hill,
Of all my joys and sorrows,
The gentle witness still.

When sick of worldly pleasures,
Leaving the busy town,
I seek thy quiet shadows,
And weary lay me down,

The forest softly whispers,
In tones of truthful might,
It speaks of earnest duty,—
Of what is wrong and right.

I listen to its teaching
With patient humble ear;
To me the beauteous language
Shall be for ever dear.

In connection with a subject so full of delights, it is somewhat chilling to think of organizations for promoting the observation of nature. The all-abounding beauty of the natural world is enough for the soul that loves in earnest, and it is like imposing fetters on a spirit that cannot live unless it be free, to subject the mind's communion with nature to rules and times and seasons and purposes. But it has been done, and that with vast benefit to thousands. Possibly there are not many in this age who can rise to the height of regarding impulse as superior to law, and hence such an institution as a Naturalists' Field-club is a good thing, a glorious thing; for it gives a healthy direction to the thoughts of all whom it embraces in its operations; and it is better for men and women to be led into the fields by the persuasions of a society than to forego the minutest part of life's share

in the glory of the great world, and its evidences of the love of its Maker. If the poetic element, which is undoubtedly the highest, morally and spiritually considered, loses by organization, there can be no doubt that social life is benefited and science promoted by the establishment of field clubs, and, for all we know, the good actually accomplished in one way may far outweigh the harm we imagine to be done in another. Not to hypothesize—for that is what we have almost engaged in—here is the report of the Committee of the Manchester Field Naturalists' Society for 1866, and we call the attention of all our Manchester readers to the fact, that if they love rambling in the country, they can have the advantage of organized rambles and good society to make an end of loneliness, and, moreover, accomplished savans to assist them in the study of the things they see, if they will join this society, and take full advantage of its enlightened provisions.

The writer of this has taken some interest in the formation and prosperity of these societies, and though given to impulse in seeking his own enjoyment, can have no objection at all to organization for those who find it needful or beneficial. Having been accustomed to out-door explorations for nearly forty years, he always believed he had little to learn as to the conduct of a party making an excursion ostensibly in the pursuit of natural history studies. There might be a little flirtation, and some very happy and prosperous courtships, all in the interests of science—that is to say, social science; but, as a rule, much knowledge would be diffused amongst the excursionists, respecting plants, insects, and even geology and meteorology. But some real curiosity was excited about the way in which a flourishing society, such as the one now occupying our attention, would get through the winter. It was, therefore, with some pleasure an invitation to address the members at one of their winter soirées was accepted; there could be no better opportunity of having a peep at a good society in its season of (comparative) hibernation. If the whole case may be judged by this one example, Field Naturalist Societies are somewhat better off in the winter than what are called "Literary and Scientific Institutions!" These last have meetings at which there is either much speaking or much performing; but the naturalists have a way of promoting social enjoyment and intellectual communion far superior to what is generally understood as the winter recreations of literary societies. At all events, at the soiree at the Manchester Athenæum, on the 18th of December last, there was a vast gathering of ladies and gentleman, and the only fare set before them consisted of dried plants, collections of fossils, drawings illustrative of botany and zoology, and a few kindred subjects, to which were added, as a makeweight, an address by the writer of this notice, who is not ashamed to say that he found it pleasant to speak to the assembly who honoured him with their audience, and hopes it was not a painful task for them to listen. One of the advantages of this sort of entertainment is that (except when the orator of the evening is on his legs) there are abundant opportunities for conversation. This is an advantage of far greater value than the promoters of tedious meetings, where there is a flood of speeches or a plethora of performances, are aware of. One of the simplest and most successful methods of getting up a private party is to invite a lot of people, and then leave them to entertain one another. That is nearly the method pursued by this society; but care is taken that there shall be abundant amusement for the eyes, with a little music and light refreshment, and the result is success. By success we mean that the society continually increases in strength, and all that join it pronounce it delightful.

During the past year there were soirées and excursions as follows:—On the 13th of March, a soiree, when Mr. James Bateman, of Biddulph Grange, gave a lecture on the Wellingtonia gigantea. On the 17th of April, another soiree, when Professor Williamson, of Owen's College, gave a lecture on fossil and extinct birds. On the 12th of May, an excursion to Hanging Woods Bank, Wilmslow, when (after tea) Mr. Holland gave an address upon the Natural Order *Cruciferae*. On the 9th of June, an excursion to Thelwall and Lymm, when Mr. Bailey (after tea) wound up the affairs with an address. On the 23rd of June, an excursion, *via* Buxton and Millersdale, to Chee Tor, when many rare plants were gathered, and there was no time left for botanizing or speechifying. On the 7th of July, an excursion to the lower valley of the Etherowe. On the 21st of July, an excursion to Bollington, respecting which occurs in the report this note: "Upon the slope ascending towards the rude summer-house called 'White Nancy,' abundance of wild thyme was observed. This is a new locality in our neighbourhood for a plant scarcely known to the flora." How some of the Manchester hotanists would rejoice to see in some of the sandy parts of Surrey, on every acre of land, thousands of round hummocks (like hassocks), this fragrant plant growing all alone, and in superb luxuriance, and to observe also the signs that after dusk every hummock is a meeting place for a soiree of rabbits, which, however, are not scarce in the fauna of the cotton city! August 4th, excursion to Knutsford. August 18th, excursion to Southport, for the Birkdale sand-hills; this was a good day, and heaps of good plants were gathered. September 1st, excursion to Capersthorne; and again there were good botanical findings. September 15th, the ninth and last excursion, this time to Marple, and thence to Romley; after tea an address was given by Mr. Bailey. It all appears so pleasant that one can scarcely glance at the list of officers, and see Mr. Grindon's name entered as secretary without concluding that Grindon is a synonym for happiness. But, with all our regard for this society, we can find fault, which is always a fortunate circumstance for a critic. The society is *too botanical*; it does not look after animals enough. One of the objects of this summer should be to teach its members how to distinguish the several song-birds of the district by their voices, flight, and plumage. We could suggest a few more agreeable tasks, but perhaps it would be more decent to observe and admire, for great things have been done to enhance the love of nature amongst the residents in a great smoky city.

On the 25th of November, the soirées commenced, when there was a display of microscopes, and a lecture on microscopic botany by Mr. Grindon. Dr. Simpson, who occupied the chair, no doubt contributed his share of light, effulgent light; for on a subsequent occasion, December 18th, he presided again, and spoke most eloquently and truthfully on the elevating tendencies of scientific pursuits. As it may interest some of our readers, and serve generally to exhibit the purport and management of these meetings, we transcribe verbatim from the report the notice of the last of the soirées of 1866, that which took place on December 18th, and with that we for the present quit the subject. The specimens exhibited included a collection of fossils, lent by Mr. J. E. Forbes, F.G.S.; the white head of an arctic fox, brought from the arctic regions by the McClintock expedition; and a collection of sixty varieties of the ivy-leaf. The two latter were exhibited by Mr. Hibberd, the lecturer of the evening. On the tables

were also the prize herbariums of the season, prepared by Mr. John Barrow and Miss Wilson; and specimens of the cones of the *Wellingtonia*, produced at the residence of Lord Crewe, and exhibited by Mr. Grindon. The chair was taken by Dr. Pankhurst, who stated that that meeting completed the seventh year of the Society's existence, and he hoped the new septenniad would be entered upon with renewed zeal. Mr. Hibberd's excellent address upon the "Essentials of Observation in Natural History" occupied considerably over an hour, and was listened to with the most cordial attention. In substance it was as follows:—

"While we all have our hobbies, success in any enterprise comes only of deep love of what we undertake, and few things awaken so lively an interest as natural history. Natural history is important and interesting to every man, since it is through what we derive from the earth, in the form of natural productions, that we are enabled to enjoy life as well as to sustain it, and that we become intellectual beings. Natural history is identified with civilization. Through natural history we understand the nature of coal, and learn how to procure it. So with all vegetable substances used for food. In every way natural history proves itself to be one of the high roads to human happiness; it makes us more complete as human beings.

"Referring to the excursions undertaken by the society during the summer months, Mr. Hibberd said it was important to remember that in order to derive intelligent enjoyment from country rambles, we must take knowledge with us. Those get the most pleasure and reward who carry out with them the most, previously acquired. 'To him who hath, shall be given,' is not more true in morals than in the pursuits of nature. Natural history helps immensely to perfect our organs of sense. A botanist is at once known by his quick eye and keen sense of discrimination. So with the ornithologist; so with the geologist: they learn how to see. How common it is to find people incapable of noticing the commonest things; it is because they have not acquired the habit of observation, such as natural history so eminently confers. What mistakes and absurdities are committed in giving descriptions, even by people who are 'well educated'! The reason is plain: they have not been observers of facts in natural history.

"Natural history teaches us to compare. We learn from it how to be cautious in pronouncing things to be different or the same. Nature never deceives us, though she submits many problems to our curiosity, as illustrated in the beautiful *Poinsettia* which (pointing to it) stood by the lecturer's side. A strange condition of the common mushroom (exhibited by Mr. Hibberd) was another apt illustration. Next, holding up the head of a white arctic fox, Mr. Hibberd proceeded to speak of the nature of organic types, and pointed out a number of very curious and interesting phenomena connected therewith.

"Another essential to the wise observation of nature is to acquire a good stock of sound general knowledge. It is of no use for a man to say, 'I will be a hotanist,' or 'I will be a geologist.' The sciences help one another. The anatomist wants some knowledge of mechanics; the botanist wants knowledge of climates and seasons. No man can learn a subject even approximately unless he gathers light and illustration from many surrounding departments. Very important is it also to take broad views of things, and to practise catholicity in our estimation of what we see and hear. We should always remember as naturalists, that we do not live in a botanic garden or in a museum, but in a world. We then perceive the relations of things, and learn to comprehend somewhat of the general scheme of creation, and to see how things fit into one another. Who sends his boy to school in order that he may become simply a mathematician or a chemist? No one. We want our boy to become a citizen of the world, and as this is the true idea of education, so is it in reference to natural history studies. Always avoid walking in a groove. To a certain extent we are constrained to it, but let us be ever striving to escape from the slavishness of it while we still keep our eyes fixed on some given point. And while doing this, never look with contempt on the studies of others, though they may not be such as we sympathise with. They all have a use. Keep an eye to truth, admiring everything in its degree.

"Lastly, while studying forms, remember that life-history is still more important. The mode of growing, of living, even of dying, for everything has its own way. Moreover, cultivate a spirit of reverence; believe that this world is a good one; and be glad if you have the power of contemplating it in the spirit and with the eyes of the poet, for the imagination is essential to sound enjoyment and genuine progress."

EAST LONDON FLORICULTURAL SOCIETY.
